ELECTRICITY AT THE MINING EXPOSITION, SANTIAGO, CHILI.

BY

Harry Bindemann

THOUGH a small local exhibition in a rather far-off corner of the world, the Mining Exposition of Santiago, Chili, recently closed has been a success, opening avenues for European and American commerce, and directing the attention of the Chilian mining public to the splendid advantages of modern mining machinery, of electric transmission of power, electric lighting and electro-metallurgy. The electric manufacturing concerns in Europe and the States have certainly much to be thankful for regarding this exposition, because the Chilian public has been able to see that electricity has passed from the stage of experiment some years ago to healthy and systematic development.

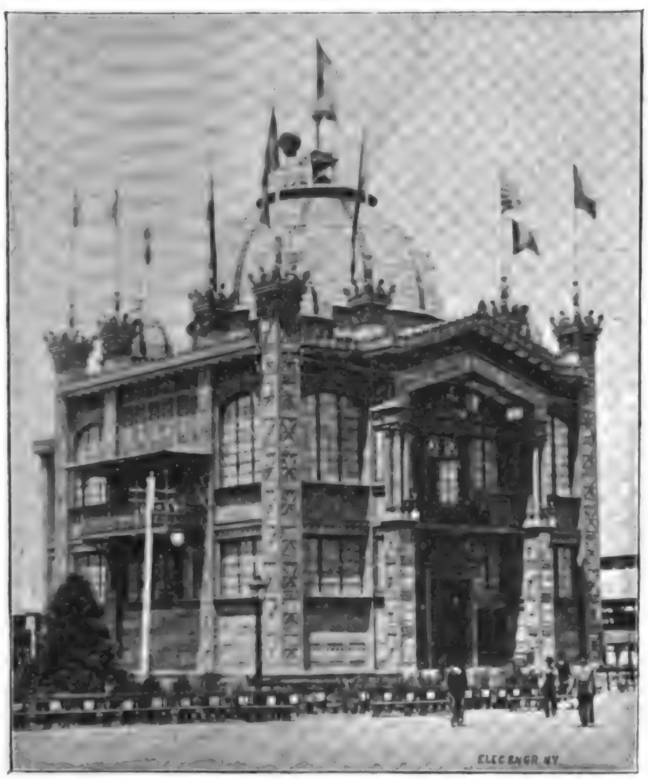

FIG. 1.—SCHUCKERT SEARCH LIGHT AT THE SANTIAGO, CHILI, MINING EXPOSITION.

Foremost among the electrical exhibits was that of the well-known firm of Schuckert & Co., of Nuremberg, Germany, now the Schuckert Electrical Company, Limited, of search-light fame at the World's Columbian Exposition of 1893. The Company were represented at the exhibit by their agents for Chili, Messrs. Saavedra, Bénard & Co., who spared neither pains nor money to develop an exposition worthy of the high reputation they are fast gaining. The exhibition of these gentlemen, who preferred to have it under their own roof instead of together with, and amongst a lot of, ill-assorted competitive machinery, was in itself a collective one, Schuckert dynamos being driven by the famous "Otto"-Deutz gas, petroleum or benzine engines, Rudolf Wolff's portable steam-engines, lubricated with oil from the Standard Oil Co., of New York, and the belting supplied by C. Otto Gehrckens, of Hamburg.

The plan of this special pavilion, Fig. 4, and the engraving of the interior Fig. 2, will show the general arrangement of the machinery and exhibition objects. Prominent among the generating machinery, as regards economy and regularity of working, besides perfect workmanship, was one of Wolff's portable 24 H. P. steam-engines, driving a Schuckert 4-pole, 19 KW. shunt-wound dynamo. There was also a 6 KW. bi-polar, ironclad, shunt-wound dynamo driven by an 8 H. P. double-cylinder "Deutz" gas engine. Besides these there was a storage battery in a separate room, consisting of 60 "Tudor" cells from the celebrated Hagen (Westphalia) firm, with a normal capacity of 250 ampere hours. The switch-board connections of these three current-generators are clearly shown in Fig. 3. The circuits for the electric motors, the descriptions of which are given later on, were all connected to one half the positive, the lighting circuits for the building and two search-lights, to the other half of the bus-bar. Now, by means of two three-throw switches I and II *b*, *c*, any one dynamo or the battery could be connected to the power or light bars, as shown in the diagram; or by closing switch III, the whole system could be worked in parallel. This division between light and power was obviously necessary in case of the small

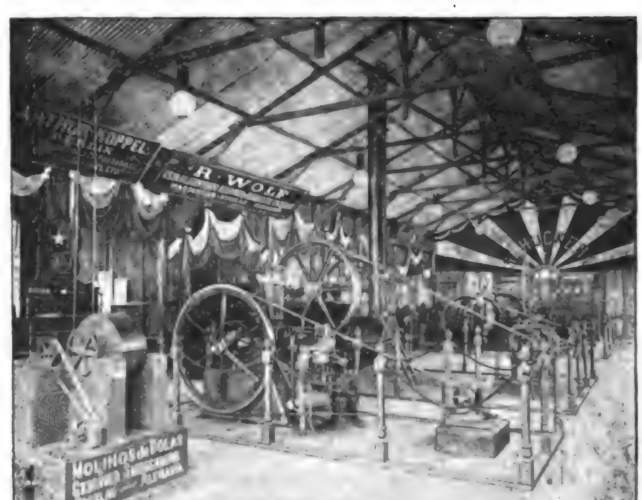

FIG. 2.—INTERIOR VIEW SCHUCKERT PAVILION.

mining railway being in use, the starting of which would naturally have produced a flicker in the lights. With the battery in parallel to a dynamo, however, this was found

to be reduced to a minimum. The contacts *a* I, *a* II, were used for charging the battery, the necessary switching on and off of the cells being done by means of a double cell switch, the idea of which is clearly depicted in the diagram.

This cell switch in general has been made a special study by the Schuckert firm, and has found very extensive use in its various developments in many of the largest central-stations in Europe. The discharging switch in this case was worked automatically, the contact-shifting handle being turned by a small electromotor, the back or forward motion of which was controlled by a delicately adjusted solenoid, shunted across the mains. In this manner the pressure of 110 volts between the lighting bus bars was kept absolutely steady. The remaining apparatus and connections are so simple as to need no detailed description.

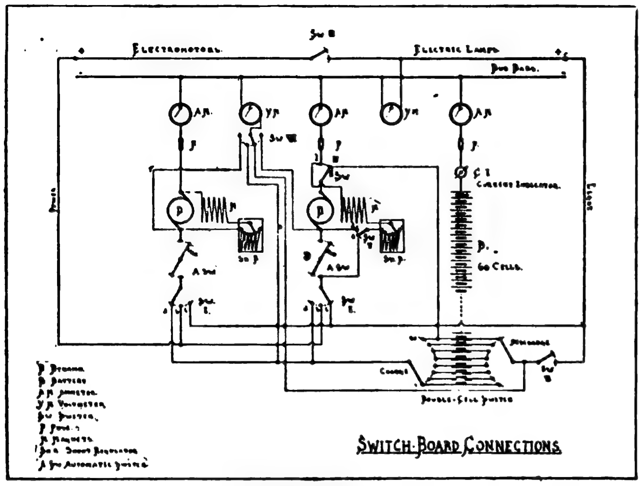

Fig. 3.—Switchboard Connections of Generators, Batteries and Motors.

There still remains for notice, however, an interesting use of the storage battery for starting the gas engine by the dynamo running for a short time as an electric motor. This is accomplished by sliding the cell-charging switch down to cell No. 20, putting switch V on contact *e*, switch II on contact *a*, closing the shunt regulator, thereby exciting the magnets of the dynamo; then throwing switch IV on contact *g*, closing the automatic switch, and slowly sliding the charging switch up again, in this manner sending the current of 20 cells through the armature and starting the gas engine. As soon as the gas engine "ignites," the automatic switch opens at the same moment, the armature current suddenly falling. By this means all starting resistance is completely done away with. Switch IV in every other case always remains closed on *f* and switch V on contact *d*. There will be also noticed on the plan Fig. 4 two smaller oil engines and a benzine engine built by the Deutz firm and driving Schuckert dynamos, which were used to furnish lighting current to other adjoining buildings, as for instance the banquet-hall, the restaurant, etc. The current generated by the larger machines before mentioned, was exclusively used for driving the different electric motors, the electric mining locomotive, two search-lights, one of 50, the other of 75 amperes; an electro-metallurgical establishment, besides the general lighting of the building.

There were further exhibited a centrifugal pump coupled on the same shaft to an electric motor, and capable of lifting 40 gallons of water per minute to a height of about 150 feet; also a mining hoist with one cable-drum, connected by spur-gearing to a 7 H. P. electric motor with reversible motion. Besides these there was a high-pressure mining ventilator capable of furnishing about 2,300 cubic feet of air per minute.

The mining railway was constructed on the overhead system, imitating the conditions existing inside a mine; the small locomotive was furnished with a 8 H. P. electric motor, driving the wheels directly by means of worm-gearing running in oil. The current entered from the overhead wire by means of a ┌┐ shaped copper sliding bar, past the starting resistance, which could be controlled from outside by a simple lever movement, and, passing the motor, returned by the copper-bonded rails.

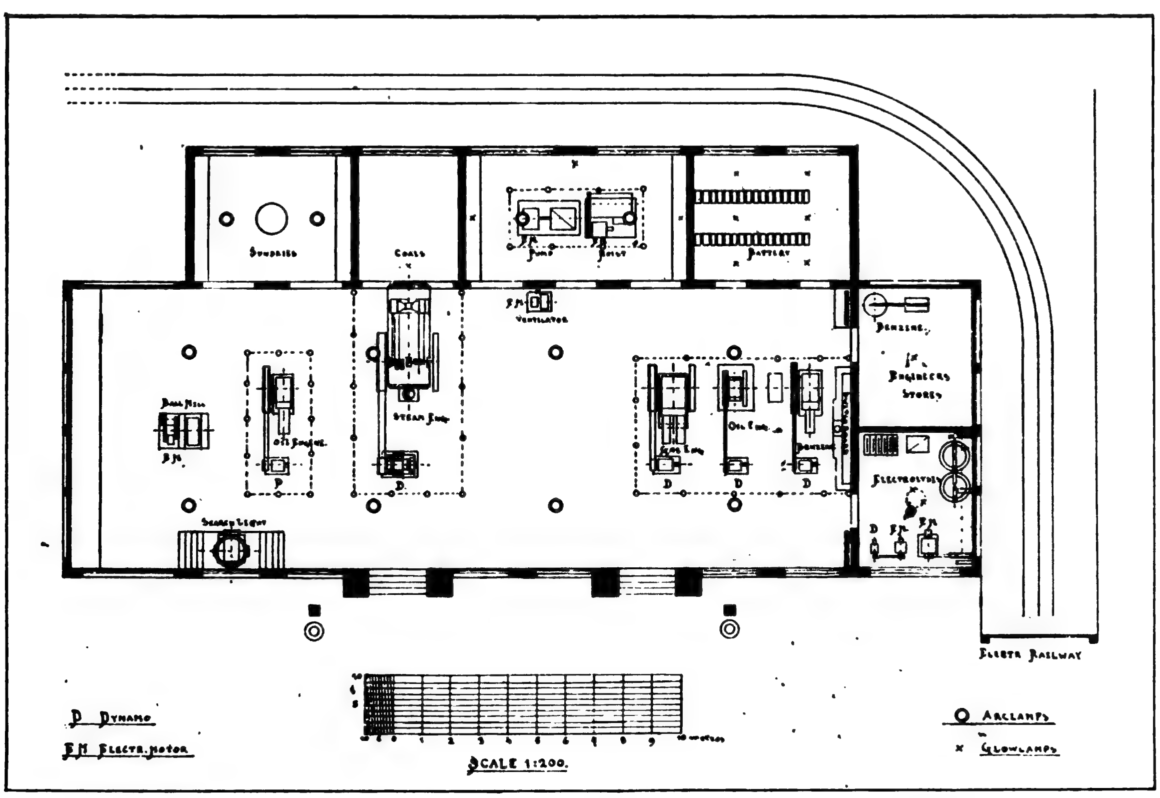

Fig. 4.—Diagram of the Schuckert Electrical Mining Exhibit.

The electrolytic process mentioned before was shown in a separate part of the building (see Fig. 4). The necessary shafting used for driving an air and acid pump, besides two stirring apparatuses, was driven by an electric motor, while the low voltage current necessary for electrolysis was furnished by a small dynamo, also driven by a separate electric motor. This electrolytic process, which was operated according to patents belonging to Dr. Höpfner, of Giessen, Germany, consists mainly in the use of a solution of low-grade copper or silver-ores, the metal of which is deposited electrolytically in plate form in a chemically pure state, the electrolyzed remaining liquid being used over again for working a certain quantity of fresh ores. The process by these means forms a complete cycle, involving a minimum of working materials and of cost.

The two search-lights mentioned, one of which was located on top of one of the handsomest exhibition buildings, shown in Fig. 1, furnished no little amusement and delight, when illuminating the romantic "Cerro Santa Lucia," at the other end of the town, or when their strong beams rested on the distant heights of the Cordillera.

A very interesting use of the storage battery for mining purposes was shown in the form of a portable lighting apparatus for mine drifts. The battery consisted of 10 small Tudor cells, filled with Dr. Schoop's well-known gelatinous electrolyte, enclosed in a box carrying the necessary switches, fuses and charging connections, the whole apparatus forming a sort of knapsack on the back of a workman. A 16 c. p. lamp which is connected to this battery by a strong metal-sheathed flexible cable is enclosed in a strong wire-guarded metal reflector, and will burn for about 10 hours.

Besides this splendid exhibit, the largest and most complete, electrically, in the Exposition, Messrs. Saavedra, Bénard & Co. had a smaller power-house for themselves including a 30 h. p. Deutz single-cylinder engine driving a Schuckert dynamo of 21 kilowatt, which was used exclusively for lighting the different avenues, buildings, festivities, etc., in the park and which of course necessitated a frequent shifting of lamps and wires. Altogether there was running an aggregate of 125 h. p. including electric motors, which furnished current for about 70 arcs ranging from 300 to 3,000 c. p., and 24 16 c. p. incandescents. The complete plant was started the evening of the opening day, being the only one ready, and ran till the end of the exhibition without a hitch. The designs and plans for this exhibit besides the erection of the complete plant were in the hands of the writer, who acted as electrical engineer to the firm.

THE SHUNT vs. THE DIFFERENTIAL ARC LAMP.—II.

(Concluded.)

BY

E. R. Knowles. C. E.

Now as to the circuits and sources of electric current upon which these lamps will successfully operate.

We may have several kinds of electrical circuits upon which it may be desired to run electric arc lamps. We may have a circuit in which the current and electromotive force are constant; we may have a circuit in which the electromotive force is maintained constant and the current is varied; or we may have a circuit in which the electromotive force is varied and the current maintained constant. The two latter are the ones met with in actual practice.

It is necessary for the satisfactory running of an arc lamp, that as the current passing through it varies, the electromotive force between its terminals shall also vary inversely with the current variations, these variations together making the relative constancy of action of the lamp. At its best no lamp runs with absolute constancy. There is always a fluctuation up or down of the current and there must be corresponding fluctuations down or up of the electromotive force, and the smaller and more frequent these variations are made the more nearly constant will be the action of the lamp. To accomplish this there must exist in the circuit an ability to vary its electromotive force within limits; there must exist a spring or elasticity, as it might be called, to the circuit.

At first the only source of electricity was galvanic batteries which were coupled together in such manner as to produce the required electromotive force and current. This arrangement was always of constant electromotive force, the current varying with the resistance in the circuit. The earlier types of main and shunt lamps were operated on such circuits with no very satisfactory results, except as they were run singly.

Any lamp with a reasonably well made feeding mechanism will run singly on any circuit, but when two or more are to be run in series on the same circuit, something more is required. The lamp must not alone be capable of quickly adjusting itself to variations of current, but there must be present the spring or elasticity to the circuit already mentioned, so that it will also adjust itself to the varying conditions upon it. No such conditions prevail on a circuit whose source of current is a battery. Its electromotive force is fixed and does not vary and when more than one lamp is run on such a circuit they do not give the best results. There was no chance for the electromotive force to vary and there was no spring or elasticity, so that the lamp ran in a more or less irregular manner even under the best conditions. With the advent of the dynamo electric generator, a change in conditions took place and circuits of constant current and varying potential were made available and it became possible to run any number of arc lamps in series upon such a circuit, as it possessed the requisite elasticity or ability to vary its electromotive force. Shunt lamps were so run, but the most successful lamps were those of the differential type. The current was kept practically constant on the circuit and the electromotive force was varied with the number of lamps or the total electrical resistance of the circuit.

Now it is perfectly possible to so adjust the balance of a differential arc lamp, the pull of the main magnet balanced against the pull of the shunt magnet, that the lamp will quickly adjust itself to the variations of the current and electromotive force and maintain a practically constant arc and so a practically constant resistance between its terminals. This being the case each lamp works as an entity in itself and does not influence, nor is it influenced by, any of the other lamps which may be running in series with it. This being so, all the lamps will operate alike and all will, if properly constructed and adjusted, have practically the same length of arc and will each give practically the same light.

Recently, in order to cheapen and simplify the arc lamp, a return has been made to the second or shunt type of lamp. It is not possible, however, to make these lamps operate in as perfect a manner in series as the differential type of lamp. The differential type of lamp is very sensitive to slight changes in the current on account of the double magnetic action to which it is subjected, but the shunt lamp has only one magnet in action, and is sluggish and does not respond as quickly to slight changes in the current, so that its resistance may vary greatly and allow one lamp to gain or lose on its neighbor, so that some lamps may be giving more light than others on the same circuit. This action is not very noticeable on circuits where the electromotive force can vary with the resistance of the circuit as in this case the distribution of electromotive force along the circuit will vary and where a lamp may have an abnormally long arc the e. m. f. between the lamp terminals will rise and the action of the shunt be greatly increased and so be brought more strongly into action and thus cause the lamp to adjust itself more

quickly to its normal condition. Until quite recently all arc lamps were run on such a circuit, the one in series with the others, like beads on a string, constituting what is known as the high potential series system of lighting.

With the recent wide-spread introduction of the incandescent lamp, new conditions have arisen. We have a return to the old constant E. M. F., varying current circuit, all of the incandescent lamps being arranged singly in parallel with one another like the rungs of a ladder; the difference between the modern circuit and the old circuit being that the modern circuit is supplied from a dynamo electric generator and not from a galvanic battery and that a higher potential is used so as to permit of a much more extended and economical distribution of current. It is also desired to run arc lamps on the same circuit with the incandescent lamps so as to render the lighting service as universal in character as possible. If the potential of the circuits was low enough to admit of the running of each arc lamp singly there would be no difficulty; almost any lamp would serve the purpose; but it is not. At least two arc lamps must be run in series. The circuit being constant in potential, the old original difficulty crops up again, namely, the lack of spring or elasticity to the circuit due to the unvarying character of the E. M. F.

The E. M. F. of the modern constant potential circuit was found to be too high for two lamps in series, so it became necessary to place a dead resistance in series with the two lamps to take up the excess of potential and it was then found that two lamps of proper construction would run satisfactorily in series on such a circuit. This was due to the fact that although the potential at the terminals of the lamp circuit was *constant*, the dead resistance introduced the needed spring or elasticity into the circuit, because, as the resistances of the lamps varied, a constant *shifting* of the *distribution* of the potential on the circuit took place, it being shifted off and on the dead resistance, so to speak, permitting of the slight variations of E. M. F. at the lamp terminals necessary to the satisfactory running of the lamps.

At first the differential type of lamp was used on these circuits with most satisfactory results, provided the lamps and the dead resistance were all properly proportioned to one another. When this was not carefully attended to, there was a tendency for one lamp to rob the other and for the lamps to see-saw, due to the causes already described. But as the demand for this style of lighting increased, the number of different makes of lamps also increased, and close competition in prices set in, with the result that the price of lamps was gradually forced down. As the price went down the quality of the lamp went down with it. It was made less substantial and everything was eliminated from it that could possibly be spared without seriously impairing the running qualities of the lamp.

Finally a return was made to the old form of a single magnet shunt lamp as being the simplest and cheapest form of lamp to build. But with the return to this form of lamp, all the original evils of such a lamp returned and the action of the lamps became unsteady to a marked degree, the lamps robbing and see-sawing, not quite as badly as in the old times on the battery circuits, because the dead resistance in circuit with them helped to obviate this in a measure, but badly enough to make their action quite unsatisfactory and all due to inherent defects already described in this form of lamp, which can never be fully eliminated.

It would seem, from all the available data on the subject, that the differential type of lamp is the best form of lamp for all arc lighting purposes, and especially so for use on circuits where the terminal E. M. F. is kept practically constant, and is the only type of lamp which gives a practically constant and steady light, and that the shunt form of lamp possesses radical and inherent defects which render it unsatisfactory in operation in any circuit, but especially so on modern constant potential circuits. A little better mechanism and a little more first cost; a little less profit to the seller and a return to the differential type of lamp, would give the public that which they desire, a better and more satisfactorily running lamp than many of those now in use.

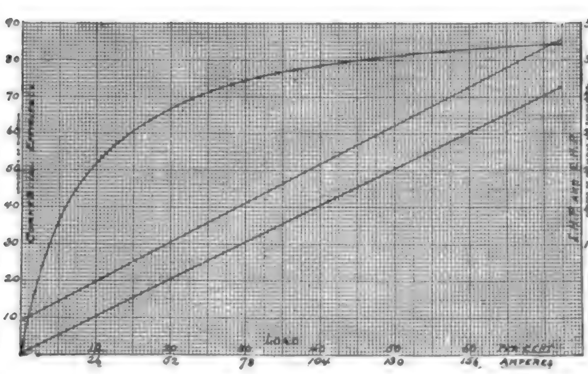
A great many ingenious forms of feeding mechanism have been devised, many of them exceedingly simple and beautiful in their arrangement, but the difficulty does not lie in this direction, it lies in the magnetic devices which control the feeding mechanism and experience would seem to point out that the type of lamp which is most free from all difficulties and which most nearly fulfills the requirements of a steady, quiet, unvarying lamp is of the differential and not the shunt type.

SOME OBSERVATIONS ON A DIRECT-CONNECTED 300 K. W. MONOCYCLIC ALTERNATOR.[1]

BY DUGALD C. JACKSON AND S. B. FORTENBAUGH.

The machine is the new monocylic alternator, manufactured by the General Electric Company, of 800 K. W. capacity—1,150 volts, 260 amperes—at a speed of 140 revolutions per minute. It is direct connected to a Russell, tandem-compound, high-speed condensing engine, which ran during the test about 15 revolutions more than the required speed. The armature is of the ironclad type, 110 inches in diameter, 10½ inches wide, with about $\frac{3}{16}$ inch clearance, and is furnished with two sets of windings. According to Dr. Louis Bell the cross-section of the main and teaser coils is the same, but the latter has fewer turns and is placed in shallower slots midway between the main coils. The pressure developed by the teaser coils was .7 of the pressure across the main terminals of the machine.

In planning the test we fully expected to make a ten hour, continuous run at full load, and determine the heating, efficiencies, etc., but were unable to go farther than slightly above half load. In the first place the engine was piped to a single boiler of insufficient capacity, and secondly, the engine was too small to carry the full load of the generator, and in addition its regulation was defective, the total variation of speed being as much as 15 per cent. Fig. 1 therefore shows an efficiency curve for slightly



EFFICIENCY CURVES OF 800 K. W. MONOCYCLIC ALTERNATOR.

above half load, and from this it will be seen that the commercial efficiency of the generating set is about 81 per cent. at half load. When these observations were made the machine was in commercial service with the regular transformer load. The commercial efficiency of the generating set is taken as the ratio of the electrical output to the I. H. P. The E. H. P. here used is taken as the product of amperes and volts, the power factor of the circuits therefore being assumed at 100. Actual measurements have shown that the power factor is at any rate over 98 per cent., and consequently the error made by this assumption is comparatively small. The diagonal lines in the figure show respectively the I. H. P. and the E. H. P. at different loads, the vertical scale for these being at the right hand of the figure. For the ordinary changes of load, the regulation of the alternator is not entirely effected by the series coils as the machine now stands, but requires considerable hand regulation. However, this can probably be improved by altering the shunts across the rectifier and series turns respectively, thus giving a greater number of ampere-turns in the series coils. This lack of regulation on the part of the alternator combined with the unsatisfactory regulation of the engine makes the performance of the generating set somewhat below the standard for this class of machinery when under ordinary working conditions, but, as a whole, the unit is a magnificent piece of mechanical construction.

1. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

LOCATION OF GROUNDS IN ARMATURES, FIELDS, ETC.[1]

BY CLARENCE E. GIFFORD.

If the work can be performed in a very quiet room, two or three cells of battery, a telephone receiver and connecting wires, comprise the necessary apparatus. In some cases two "table binding posts" and a foot or two of No. 18 or No. 20 bright iron wire will be a convenient addition. Where noise will not permit of the use of a telephone, a dead-beat reflecting galvanometer, a milli-voltmeter, or some other form of delicate and rapid working visual indicator must be used instead. If an armature is to be tested without removing it from the machine, connection with the battery may be made through the brushes, first making certain that the short-circuiting switch is open, if dealing with an arc machine. The points of connection with the battery need not be diametrically opposite, and may be made by the wires being firmly pressed against the commutator by an assistant, if more convenient.

Good electrical contact between metallic surfaces can better be secured by cleaning the same thoroughly with kerosene, which removes foreign matter, and is so fluid that it will in no way interfere with perfect contact, when moderate pressure is applied. Especially when making measurement of resistance of armature sections, it is even advisable to have the surface of the commutator quite wet with kerosene during the operation, as this avoids trouble from grease or dirt which might get on the surface from handling, subsequent to cleaning, and it also prevents the contact points becoming oxidized by any sparks which may occur at the moment of breaking contact. True, the oil is an insulator, but we use it in this case as a detergent simply.

Connection being made between battery and commutator, first determine whether the armature circuit is complete throughout. If the circuit is complete, a click will be heard in the telephone when the two terminals of the same are brought in contact with any two contiguous bars of the commutator, or when contact is broken. If an open circuit exists on either side of the circuit, of course no sound will be heard in the telephone when used on that side, except when connection is made or broken by it between the bars lying on opposite sides of the break. See Fig. 1.

Close any open circuit temporarily by bridging between the two bars with a drop of solder. Two or more breaks can evidently be located by suitably shifting the battery contacts and searching as before. Open circuits will, of course, when an armature continues in work, soon cause burns between the bars that will indicate unmistakably their location. Having closed any open circuits, and the battery being connected to two points of the commutator, approximately opposite each other, one terminal of the telephone is connected to the armature shaft, or frame of the machine, and the other terminal is drawn completely around over the surface of the commutator, while the telephone is held to the ear. If

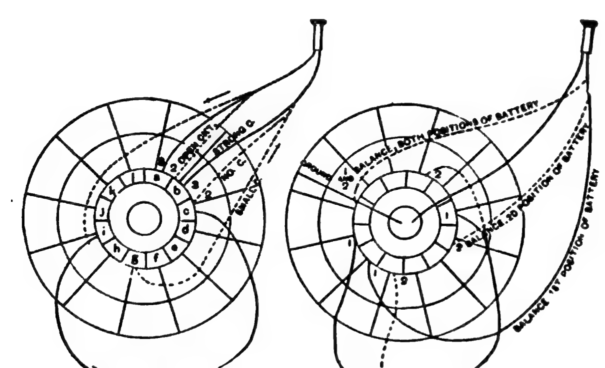


FIG. 1. FIG. 2.

only one ground exists, two balancing points, or points giving the least noise in the telephone will be found.

In an armature of ordinary construction, one of the points so found will be on the bar nearest the real ground, while the other balancing point bears what might be termed a "bridge relation" to the first, being at practically the same potential; the armature itself forming in reality a veritable Wheatstone bridge.

Now, shift the points of battery contact a few bars either way and the true ground, if but one exists, will be indicated in precisely the same position as before, while the other balancing point will shift every time the battery contacts are shifted. See Fig. 2.

If two grounds exist, two balancing points will be found, as before, but both points will shift more or less when the battery contacts are shifted, provided the grounds lie on opposite sides of the same battery contact.

In the case of one ground, having determined its location approximately, fix it as closely as may be by making and breaking contact with the telephone terminal on each of the more quiet bars, separately, until by comparison, the two giving the faintest clicks are determined. If your hearing has served you correctly these two bars lie nearest the trouble, the fainter one being the nearer. Prove the non-existence of a second ground by placing one of the battery contacts on the first bar to the right of the apparently permanent balancing point just found, and then on the first bar to the left of said point, the other contact being nearly diametrically opposite. This balancing point should still remain unchanged if no other ground exists.

The next step is to connect the battery to these two bars just

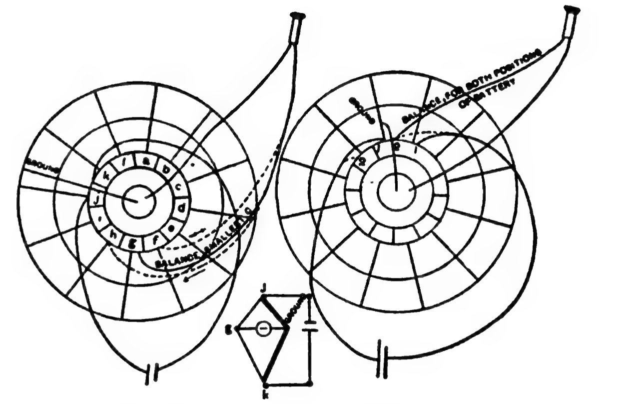

FIG. 3. FIG. 4.

fixed upon as lying nearest the trouble. The armature still forms a "bridge," the portion included between the two contiguous bars to which the battery is now connected forming the one side, and the remainder of the armature, the other side. See Fig. 3.

One of the telephone terminals is now connected to the shaft as before, and the other terminal again drawn around the commutator. If the balancing point is found, say one-sixth to one-half, the long way around from one battery contact to the other, (these contacts being on two contiguous bars) the trouble lies in the coil between those two bars, and the point of trouble divides the coil in the same ratio as the balancing point divides the remainder of the armature, the ground and the balancing point being respectively nearest the same battery contact. If the balancing point falls on the same bar as one of the battery contacts, the ground is located on that bar or on the lead between it and the armature, provided the balancing point is found to be upon the same bar when the battery contacts are both shifted one bar to the right or left of their original position. See Fig. 4.

If the balancing point appears to be found within three or four bars from one of the contacts, the precaution should be taken to test its correctness by moving both battery contacts one bar toward the balancing point. If the trouble was between the battery contacts when in their previous position, this shifting of the contacts will now throw the balancing point clear around onto the contact which was, in the previous position, farthest away from the balancing point. If, on the contrary, the balancing point remains unmoved by this shifting of the battery contacts, it shows that this balancing point is the point nearest the real ground, and that the ear was deceived in its first supposed approximation, which, with due care, however, is not likely to occur.

If such error has been made, the new point, as indicated, together with first the bar on one side of it, and then on the other, must be tried as points of battery contact; or, much better, make a new start with the contacts nearly at opposite sides of the commutator and proceed as before. A single 20,000 ohm ground on a one ohm armature should be located accurately in not over three minutes, in a quiet room. High resistance grounds require more battery and more care. Armatures of very low resistance also offer greater difficulty.

Where two grounds are found to exist, as indicated by the change of location of both balancing points, under the conditions before stated, when the battery contacts are shifted, the following mode of procedure will answer the purpose well, and is simple. Fix the battery contacts at any two points of the commutator nearly opposite each other, preferably at points to be determined by trial, that will cause the balancing points to fall nearly diametrically opposite to each other, and determine and mark the two balancing points, as then shown. Now place the battery contacts on the balancing points just found. If only one ground exists, the two balancing points and one battery contact will all be coincident in one point. If two grounds exist, both balancing

1. Abstract of a paper read before the American Institute of Electrical Engineers, Niagara Falls, June 26-30, 1895.

points will be shifted from their former position. Open the armature circuit by unsoldering one of the ends of a coil connecting with the lead of the bar that is marked in the first part of this test, as one of the balancing points. Place one of the battery contacts on the armature shaft, and the other on the marked balancing point that is farthest from the point where the circuit has been opened. Next place one telephone terminal on the first bar to the right of the opened wire, and draw the other terminal from the same point, toward the right, over the surface of the commutator. The telephone will be absolutely silent until the moving terminal has just passed the ground nearest to it, and strikes the first bar beyond the same, when it will click. This ground lies in the coil between this first bar giving a click and the one passed just previously, or else in the said previous bar.

The other ground is obviously to be located in a similar manner, by placing one telephone terminal on the bar just to the left of the open wire, and from that point searching toward the left with the other terminal. Only in cases where one ground is of very low, and one of very high resistance will any difficulty be experienced in locating both accurately before either is removed.

The coils thus indicated may have their terminals unsoldered, when it can be readily ascertained with each, whether the ground be in the coil or in the bar just preceding it.

If scientifically inclined, or if otherwise preferable, the circuit may be opened at a point somewhere midway between the two indicated coils instead of disconnecting those coils, and the exact location of each ground determined as follows: Take a piece of "broom wire" about 18 inches long, new and clean, screw the ends firmly into two clean, brass table binding posts, and into the other holes of the same posts, screw the battery terminals. Have an assistant press the corners of the bases of the binding posts into very firm contact with the two bars that lie at the ends of the indicated coil, observing the directions previously given for securing clean contact. Place one telephone terminal in contact with the shaft, and with the other find the balancing point on the wire. This point will indicate the relative position of the ground in the coil, or commutator bar, as the case may be. If more than two grounds were suspected, the two lying the farthest apart would be approximately located by the first part of the two-ground process, and if these coils were not disconnected before proceeding farther, it would be well to make two openings in the circuit, close to and lying between these outer grounds; then locate definitely these two extreme grounds, and proceed with the remaining section somewhat as with a complete armature, except that you would commence by connecting the battery to the terminals of this section, and would then bridge the telephone from the shaft to the different portions of the section, and would complete the process by applying the remainder of the two-ground test.

In dealing with a cross connected Gramme ring, an obvious change would be made in the points of application of the battery; and as many points of apparent trouble would be indicated as there were series of cross-connections.

After location of these points it would be necessary to use the auxiliary wire loop, as before described, between these points, to determine which is nearest the trouble. This fact being determined, it would in case of a single ground (indicated by the permanency of the balancing point) become necessary to remove the cross-connections from two bars before proceeding farther. The auxiliary wire loop would properly be used to complete the process.

The ordinary "closed coil" ring or drum armatures are types to which these methods are directly applicable.

The sections of open coil armatures would receive the same treatment as field coils.

Whenever necessary to deal with wet grounds in testing, it is better to make at least four tests, reversing the battery after each test, and taking the mean of the four determinations.

Field coils, also any wires of uniform cross-section, the extremities of which are accessible and within a reasonable distance of each other, can of course be easily tested for grounds by soldering or firmly clamping a bare wire of suitable size between the extremities of the conductor to be tested, applying a battery to the junctions, and bridging with a telephone between the bare wire and the object upon which the conductor is grounded. This will give only the location of a single ground, or the "resultant" of two grounds. A "T.-H." rheostat should have the battery connected to the two extremities, and the point of apparent ground determined by bridging with a telephone between the frame and the several contact plates. Then apply the battery to the frame and point of apparent ground, connect one terminal of the telephone with each extremity successively, and search from it toward the center with the other terminal, as in the case of searching for two grounds in an armature.

In determining the location of grounds that are of very low resistance, a good induction coil similar to that used in the Blake transmitter may be used with advantage in connection with the telephone receiver. The receiver is placed in circuit with the secondary of the coil, and the "bridging" is done with the primary. With high resistance grounds the best results are obtained by using the receiver only.

THE CAUSE OF DEATH IN ELECTRIC SHOCK.[1]

BY A. M. BLEILE, M. D.

The data bearing on the subject in general are quite meagre, especially as to the amount of current which actually passed through in fatal cases. In all my experiments dogs were used.

In the first experiment 525 volts, 2 amperes were applied for 8 seconds; in the second, 220 volts, 1.2 amperes; in the third, 106 volts, .4 ampere, 10 seconds; in the fifth, 96 volts, .35 ampere, 2 seconds; in the sixth, 52 volts, .3 ampere for 1, 2 and 4 seconds; in the seventh, 70 volts, .32 ampere, ½, 1 and 2 seconds was used.

Before the application of the current a canula was put into the trachea so arranged that it could at once be connected with a bellows for the purpose of giving very complete artificial respiration. Respiration was set up as soon as the current was off and this was continued for periods varying from 20 minutes in the first case to 2½ hours in the last, and in no instance was resuscitation accomplished. Further work was carried on for the sole object of studying the effect of the current.

The result depends, somewhat independently of the weight of the animal, on three factors: On the voltage, on the amperage and upon the time of the application. A variation of either one of these factors may change the result—that is, a lower voltage with lesser amperage applied for a longer time will have the same effect as a current of higher voltage or more amperage applied for a shorter time.

In all cases this examination was made immediately after death, and at first we wished to study the changes produced upon the heart, so that the incision was made through the chest walls and the heart exposed as rapidly as possible. This organ presented the following peculiar conditions. The left side was completely relaxed, the right side was intensely gorged with blood, as were also the large veins in the immediate vicinity of the heart, and the little appendages of the upper portion of the heart were found beating regularly, strongly and synchronously. Pressure on the heart caused a contraction of the other parts, and from this it was evident the death was not due primarily to the destruction of the heart fibers. In addition it was noted that the deep and extensive cuts made in the tissues were free from blood, and that the arteries were quite small and contracted. This excluded a direct effect upon the heart, and, having shown by artificial respiration that the stoppage of this function was not the cause of death, other causes were to be looked for.

It was supposed that the current immediately struck the pneumogastric nerve stimulating those fibres which control the heart in that they have the power of arresting its beat, when strongly stimulated. To test this view, resort was had to the hypodermic injection of atropine, the action of which drug is to paralyze the nerve fibres and thus prevent their action on the heart when stimulated. The animals were not rendered more resistant by the drug, and the theory as to the role of the pneumogastric nerve was abandoned. To test the view, that the action of the vascular nervous system was the cause of death, we resorted to the hypodermic use of nitroglycerine. It is known of this drug that it powerfully affects the arterial system, causing, when given in larger doses, an extreme dilatation of the arteries, and a consequent great lowering of the blood pressure.

The first animal received $\frac{1}{15}$ of a grain of nitroglycerine and, when the effects were fully established, a current, which was known to be fatal, was thrown in; namely 50 volts, .24 ampere for 4 seconds, but the effects produced by this current soon passed off and there was complete recovery. Then 97 volts, with .54 ampere were thrown in for 1 second but this caused death. The animal was then brought moderately under the influence of the nitrite of amyl, (a drug having a similar action to nitroglycerine) 52 volts with .24 ampere were thrown in for 3 seconds, (this by the way being a fatal dose ordinarily,) without producing death. Fifty-two volts, .25 of an ampere for 4 seconds, also a fatal dose, failed to produce death. Fifty-two volts, .3 of an ampere for 6 seconds produced death, but after the current was taken off, the animal made 22 deep, regular respirations though not a trace of the heart beat could be made out, this incidentally proving that stoppage of the respiration is not the primary cause of death.

No. 24 was a pointer dog in excellent condition, weighing 34 lbs. Nitrite of amyl was given until the effects were fully marked. Fifty and five-tenths volts with .2 ampere were given for 3 seconds; after a pause the same quantity was given for 6 seconds, followed by recovery. Three days later the same dog, who showed no effects at all of the previous treatment, was given—without the nitrite of amyl—51 volts, .2 ampere, 4 seconds, producing death.

The statements made in regard to the cause of death by electricity are so at variance with one another that it is unnecessary to review them here. Among other plausible reasons it has been stated that the current has a direct disintegrating effect on the brain and nerve tissues and that herein is to be found the cause of the fatality. The disintegrating effects of the current on the

1. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

brain and nerve tissue said to follow are not to be seen microscopically and the microscopic examination of these organs so far as made by us failed to reveal any change in their structure. It would appear therefore that death in electric shock is entirely due to the fact that the current produces a contraction of the arteries through an influence on the nervous system, and that this constriction of the arteries throws in such a mechanical impediment to the flow of the blood as the heart is unable to overcome, and that, where drugs are given to counteract this effect, much larger doses of electricity than the ordinary can be borne. While artificial respiration may be of value in simple stunning, when larger doses have been taken, no rational means of resuscitation have as yet been suggested.

The current was obtained from a surface wound alternator giving an approximate sine-curve.

PROPERTIES OF FUSE METALS WHEN SUBJECTED TO SHORT CIRCUITS.[1]

BY WALTER E. HARRINGTON.

The law bearing on the relation existing between the diameter of fuse metals and the minimum currents required to fuse the metals, when sufficient time elapses for the fusion to occur, as enunciated by Preece, Forbes and others is $C = a\ d^{\frac{3}{2}}$ where C = Current in amperes, d = Diameter of wire in inches, a = Constant depending on the metal.

The law is not rigorously true but can be depended upon very closely, particularly in the smaller diameters. In the larger diameters the law certainly does not hold true, as has been shown by different observers.

In the course of his professional work the writer has had occasion frequently to desire to know what current would flow through fuse metals on 500-volt short-circuit work. There being absolutely no literature on the subject and the data being obtained only by experiment led to the following series of tests:

The sizes of fuse wires employed was such that the current flowing through them would not exceed 500 amperes, this being determined by the adjustment of the Westinghouse magnetic circuit breaker employed.

In the following tables the first column gives the size of wire in B. & S. gauge; the second column gives the circular mils. The third column gives the mean of determinations as given by the indications of the C-S magnetic circuit breaker. The fourth column gives the constant B entering into the formula $C = B\ d^2$, where C = current in amperes passing through the fuse metal on a short-circuit. d = diameter of fuse metal in inches. B = constant depending on metal and voltage of circuit short-circuit is made on.

TABLE I.

COPPER.

B. & S. Size Gauge.	d^2 C. M.	S. C. Amps.	B.
30	100	39	390,000
29	126	44	350,000
28	159	62	390,000
27	201	80	398,000
26	254	116	456,000
25	320	140	437,000
24	404	225	556,000
23	509	300	589,000
22	642	370	576,000

By averaging B the law for copper wires on 500-volt short-circuits could be stated to be: $C = 460{,}000\ d^2$; or, expressed directly in terms of circular mils, the current which will flow in copper wires on 500-volt short circuit will be:

$C = \frac{C.\ M.}{1.9}$, where C = current in amperes, C. M. = circular mils.

TABLE II.

ALUMINUM WIRE.

Size B. & S. Gauge.	C. M. d^2.	S. C. Amperes.	B.
24	404	200	500,000
21	810	290	358,000
20	1021	325	318,000

For aluminum the law for 500-volt short-circuit currents would be: $C = 392{,}000\ d^2$; $C = \frac{C.\ M.}{2.6}$.

There was one very pronounced peculiarity in the action of aluminum during the short-circuits; the metal seemed to burn longer and pieces of metal would come down after the explosion, still burning.

TABLE III.

STOCK (LEAD AND TIN) FUSE WIRE.

Size B. & S. Gauge	Rating Fuse Wire Amperes.	C. M. d^2.	S. C. Amperes.	B.
24	1	404	50	125,000
21	3	810	115	156,000
19	5	1252	130	106,000
17	7	2048	230	118,000
15	10	3256	290	86,000

For fuse metal (ordinary commercial lead and tin alloy) the law for 500-volt short-circuit currents would be: $C = 118{,}000\ d^2$; $C = \frac{C.\ M.}{9}$.

Copper gave the best result as regard quantity of current per cross-section of metal. This is shown in the formula for copper

$$C = \frac{C.\ M.}{1.9},$$

where, compared to the other metals, the current per circular mil is a maximum, and that the amount of metal to disintegrate for a given current would be a minimum. In all the tests the behavior of the copper short-circuits was noticeably short and attended with a loud explosive report, with but little comparative flash.

In the use of the law for practical work where fuses had to be employed for cases beyond the values as determined by test, the values as obtained by extrapolation in every instance fulfilled the requirements, demonstrating the practical correctness of the law.

TABLE IV.

LAW.

30	100.5	11	39
29	126.7	12	44
28	159.7	14½	62
27	201.5	17	80
26	254.0	20	118
25	320.4	24	140
24	404.0	29	215
23	509.4	34	298
22	642.7	41	340
21	810.1	48	405
20	1021.5	56	510
19	1252.4	67	625
18	1624.3	82	812
17	2048 2	98	1024
16	2582 9	115	1291
15	3256.7	140	1625
14	4106.8	168	2053
13	5178.4	195	2589
12	6529 9	235	3264
11	8234 0	280	4167
10	10381.0	330	5190
9	13094 0	395	6547
8	16509.0	470	8000
7	20816.0	560	10000
6	26250.0	670	13000
5	33102.0	790	16000
4	41742.0	950	20000

In Table IV, column 1 gives the size in B. & S. gauge of the copper wires; column 2 gives the circular mils; column 3 gives the minimum fusing current as determined by Preece's law, $C = 10244\ d^{\frac{3}{2}}$, and column 4 gives the fusing currents on 500-volt short-circuits as determined by the law, $C = 470{,}000\ d^2$, enunciated by the writer. The natural conclusion arising from a knowledge of the above data is that fuse metals are under no circumstances to be considered in the light or nature of a protection.

1. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

MUNICIPAL LIGHTING AT SPRINGFIELD, ILL.

At Springfield, Ill., an interesting experiment in municipal electric lighting has been started. As the debt of the city was up to the legal limit, no obligation could be incurred for the establishment of a municipal plant. Sixty men of property loaned their credit to the city, and a lighting plant has been set up. It has been leased to two electricians for five years on a contract to supply the city with light at $60 a lamp. Appropriations will be made by the city at the rate of $113 a lamp, and the difference turned into a sinking fund, which will extinguish the debt incurred in five years. Then the city expects to run the plant itself.

ELECTRIC TRANSPORTATION DEPARTMENT.

THE SUBSTITUTION OF ELECTRICITY FOR STEAM IN RAILWAY PRACTICE.[1]

BY DR. LOUIS DUNCAN.

In an address delivered before this Institute in June 1892, Mr. Frank J. Sprague spoke of the coming development of electricity as applied to railways, and outlined his views as to the direction of this development. In the last three years great extensions have been made in electrical transportation, and it seems well to review briefly the amount of these extensions and their direction. In this paper I shall consider electric traction as it stands at present, not the possibilities of the future.

In the last seven years electricity has largely taken the place of horses for tramway work, and it is now beginning to replace cables, although the latter have been recently installed at great expense. At first the lines were confined to the limits of towns and cities, but they have been extended first into the suburbs, and then to neighboring towns, and the extensions have brought them in competition with the steam roads. The reports of the earnings of the Railroad Companies in the United States, shows that after paying fixed charges, only a small amount of the net profit remains to be applied to dividends on the stock. Any general decrease in the earnings even if it is only a small percentage of the total amount, will wipe out the narrow margin that is now applied to dividends, and the absorption by the electric lines of the local travel formerly conducted by the steam lines promises to do this. At first the managers of the larger steam roads ignored the growth of their electrical rivals, but the time has come when they can no longer ignore the decrease in the receipts from their local passenger travel, and they are beginning to face the difficulty and to carefully study the situation.

In this paper I will briefly take up the following questions:—

1st. Given a railroad system at present operated by steam: will it pay to change entirely to electricity, or to make a partial substitution, and how should the change be made?

2nd. If entirely new lines are to be built, is it likely that it will pay to equip them electrically, and how should they be equipped?

3rd. I will describe the equipment of the B. & O. Tunnel Plant and draw from it what morals I can.

In order that it should pay a railroad to make a change in its motive power, the effect of the change must be either to increase the receipts or decrease the expenses by an amount equal to the interest on the cost of the change. That is, there should theoretically be such a gain; practically, the amount should be greater in order to justify the change, to take into account those elements not capable of exact calculation, and also the fact that an increase in the fixed charges of a road is a more serious matter than the mere amount of it, for although the average for a number of years might show a gain by the substitution of electricity, in a bad year the increased fixed charge might cause difficulty.

There are two very distinct sides to the question of transportation, the passenger side and the freight side, and their requirements for good service are very different. First, taking up the question of passenger travel, the receipts of a road are increased by running trains at short intervals and at high speeds, and this is a condition peculiarly favorable to electricity. On an electric line short trains equally distributed over the track, give a greater station efficiency, and the lowest cost of equipment of both station and line. The cost of train service is somewhat greater, but is compensated by the saving in the other items.

The cost of hauling a given number of passengers between given points by steam is greatly increased when the number of trains is increased. The efficiency is less, and the cost of equipment and of train service is greater. Wellington states that doubling the number of engines for a given traffic, increases the cost of transportation about 50%.

On the other hand if we take up the question of freight traffic, the conditions of greatest economy are reached when trains of a maximum weight are hauled by a single locomotive. The tendency in late years has been in the direction of increasing the size of the locomotive, the capacity of the cars and the length of the trains. These changes have necessitated more solid and expensive road beds, heavier rails, and general strengthening of bridges. The outlay has been enormous, but the decreased cost per ton mile for freight transportation has shown the wisdom of the change. On one of the larger roads which publishes careful yearly statistics, I find that the cost of transportation per ton mile in 1870 was 1.15 cts. and in 1890, .56 ct., on another road it was 1.9 cts. in 1864 and .447 ct. in 1893. The number of tons per train mile on the first road in 1870 was 103, while in 1890 it was 226. In attempting to carry on traffic of this kind by electrical locomotives operated from a central station, we find that we are at a great disadvantage because of the irregular service necessitated by the freight traffic and the unequal distribution of the load along the line. Suppose for instance that there were two stations supplying the line and that the traffic was uniformly distributed along it, then the capacity of each station would be one-half of the total required capacity. Suppose, however, that the entire traffic was concentrated in one train, then each station would have to have a capacity equal to the total power required for hauling the entire traffic, as the train would be first supplied from one station, and then from the other. The line also would have to have a capacity suitable for handling the total traffic. If a number of heavy trains were used, and the traffic was irregular and liable to be congested at one point as in the case of freight service, then again the capacity of the stations would have to be greater than that required to supply one-half of the normal traffic. If we were to decide to transmit the current to a longer distance and to supply all the track from one station using transformer devices along the line, then the capacity of the station itself would only be that required for the normal traffic of the line, but the transformer devices would have to be sufficient to handle the maximum traffic of the section which they supplied, and would have to be given a capacity greatly in excess of their average load in order to supply this energy. We must distinctly bear in mind in considering the application of electricity to steam roads that any departure from a uniform distribution of load along the line will increase both the cost of equipment and the cost of operation.

In looking over the reports of the same road from which I have given freight statistics, I find that in 1870 the receipts per passenger mile were 2.09 cts. while the expenses were .59 ct. In 1890 the receipts were 1.9 cts. while the expenses were 1.47 cts. During this period the passengers per train mile have decreased from 79 to 59. Comparing these figures with those given for freight transportation, we find that the two types of traffic have gone in opposite directions in the period we have been considering. The amount of freight transported per train mile has more than doubled, and the expenses have decreased more than one-half. The passengers per train mile, on the other hand, have decreased, and the expenses have changed only a slight amount, notwithstanding the greater economies that have been put in force in the interval. Passenger traffic has come in the direction in which electricity is the most economical for transportation; freight traffic, on the other other hand, has gone in the direction where electricity becomes most costly. It might be argued that some new scheme for freight transportation by electricity might be used, but it would be difficult to devise any system more economical than that in present use, and the great amount of through traffic on freight lines precludes the possibility of devising any system which differs radically from that at present in use. For instance taking the figures from the records of the Pennsylvania Railroad for 1893, I find that the freight mileage of foreign cars on the lines of the Pennsylvania Road east of Pittsburgh is in round numbers, 370,000,000, while the freight mileage of home cars is 436,000,000 making almost 46% of the total mileage made by foreign cars. It would seem then, impossible to change the present system of freight traffic without disorganizing the service and decreasing the freight revenue of the road. The importance of freight traffic is shown by the fact that the earnings from freight on all the roads in the United States are between two and one-half and three times as great as those from passenger traffic. The New York Central Railroad Company in 1892 received from their freight traffic $26,000,000 and from their passenger traffic, $13,000,000. On the lines of the Pennsylvania Railroad east of Pittsburgh, the freight receipts were $47,000,000, as against $17,000,000, for passenger receipts.

Suppose then, the question comes up before the managers of a road as to whether they are to equip their lines to be operated entirely by electricity. It seems to me as matters now stand, it will not pay trunk lines to change the method of operation for freight traffic, and the question to be considered would be the operating of the lines partly by steam and partly by electricity. Let us consider if it is possible to run the passenger service wholly or partly by electricity. Considering a two track road doing a through as well as a local business I think we can decide that unless the case be an exceptional one, it will not pay to equip the main line electrically. It is necessary that the through express service be continued, and that the freight service be continued, and an attempt to operate the local trains with the through trains could not be successful if there was any considerable amount of through traffic. With a four-track road the condition of affairs is somewhat different. If the road operates between cities acting as terminal points for all passenger traffic, as with some of the

1. Inaugural Presidental Address delivered before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

lines between Boston and New York, then by equipping all four tracks it would be possible to run express service at short intervals on two of the tracks, and on the other two tracks to run freight and local trains. At present it would not pay to use electric locomotives operated from a central station for the freight service, but the local service could be operated electrically, and as the speed of the local trains would be approximately equal to that of the freight, there need be no serious interference with the traffic. We would then have express passenger service working under favorable conditions, that is, with a number of trains evenly distributed; a local service operated under similar favorable conditions and with no interruption to the freight traffic. If the road however is to transport a considerable number of foreign cars, as for example the New York Central or the Pennsylvania Railroad, then the condition of affairs for express service would not be so favorable, and the question of the equipment of the tracks for express service would have to be carefully considered. As far as the branch lines go, whether it would pay to partially or wholly substitute electricity for steam, depends upon the local conditions. A long branch with a small amount of local traffic it would not pay to equip, but on a short branch with considerable passenger traffic and comparatively little freight traffic such equipment would pay. I find that in 1893 the total number of through passengers carried by the New York Central Road was 234,650, while the number of local passengers was 21,978,979. It will be seen that the through traffic is but a small percentage of the total number of passengers, and that the question of preserving the local traffic is of great importance. Now, the greater part of this local traffic will in the next few years be taken by the electric roads paralleling the steam roads unless some effort is made either to control the electric roads or to give an equally good service between adjacent towns. This latter is possible using the ordinary steam tracks only when the distances between towns are small and the amount of freight or through traffic is also small.

There are certain kinds of local traffic which the steam roads must, to a large extent lose, and which in the nature of things they cannot regain. In large cities having a considerable suburban traffic the trolley roads, forming as they do a network of lines within the city and extending in every direction into the suburbs, offer advantages with which the steam roads cannot compete. In Philadelphia one of the large steam lines lost so much traffic that it has attempted to regain it by reducing prices and increasing the number of trains. In this effort it has partly succeeded, but at the cost of greater expense and decreased receipts. To counterbalance this loss at central points railroads may hope by the introduction of electricity, to increase their earnings along the lines and on their branches.

As to the nature of the equipment that will be required it would depend on the work to be done and the branch that is to be equipped. In some cases it might be well to use single electric cars running on the steam tracks between towns and on the local tram lines in the towns. As the speed would be very different in the town and on the railroad line, and as the voltage could also be different, it would be well in this case to use a number of motors on the car, and to use a series parallel controller, the motors being in series for the town traffic. For instance, suppose we wish to run at a maximum speed of forty miles per hour between two towns, and it is economical to use 1000 volts on the line, we could use two motors on the car, run them in parallel on the main line at a speed of forty miles per hour; while in town, with a voltage of 500 we could run them in series at a speed of 10 miles per hour. I can hardly imagine a case where the three-wire system could be economically used for such service on the steam lines.

The condition of affairs in electric transportation is at present, curious. The trolley companies by extending their lines, are working from tramway transportation to through transportation. They are attacking the problem by development from small motors to larger ones. The railroad companies starting with the large units are coming down in the direction of the present trolley systems, as in the case of the Nantasket Beach Road of the N. Y., N. H. and H. Co. Perhaps in the future they will meet and some standard electrical system will be adopted for the present steam road. I think then, that in the case taken up, the policy of the road will be to equip those branches for which the conditions are favorable with a trolley, run comparatively large motor cars capable of drawing one or two ordinary passenger or freight cars as trailers, using the present steam service for their freight traffic when necessary. This will allow the necessary through travel, will give the required local service between towns, and will not interfere with the freight traffic.

As for the systems to be used for such services I believe that at the present moment the continuous current overhead trolley system is the only one that can be selected with a certainty of successful operation. It gives a minimum complication in the way of conveying the current to the cars, it allows a considerable range of speed with a comparatively high efficiency, and our experience with it is such that successful operation could be at once guaranteed. By using different voltages in the towns and on the line, both high and low speeds can be obtained. If the line to be operated is to be very long, it might be best to use rotary transformers at different sub-stations along it, the line being supplied by continuous currents from the sub-stations. In fact the three systems that are at present possible, are first, the ordinary direct current system, second, a system in which direct currents are used on the line and rotary transformers supplied by alternating currents are placed along it, and third, a two or three phase system supplying rotary field motors on the cars. In the latter case, it would be well to employ different periods in the towns and on the lines.

The second case which I wish to consider is that of roads built for an entirely new electrical equipment such for instance as the elevated roads in Chicago, and the underground rapid transit road in New York, or the proposed Washington-Baltimore Boulevard line. In most of these cases, the traffic is almost entirely a passenger traffic, and the conditions are especially favorable for the operation of electricity. Taking first the case of the New York underground road, there will probably be required about 150 trains for local service, each train having five ordinary cars and a motor car. For the express services there would be about 25 trains, of say, four ordinary cars with a motor car. For this, it would probably be best to use the direct current three wire system, one of the cars on the train being equipped with motors and acting as a locomotive. With four motors on a car the system would be efficient at all practical speeds, and, if desired, a large part of the energy could be thrown back on the line when the cars are being stopped. In the case of the local trains a simple calculation will show that a very small part of the total energy expended is used in overcoming the track resistance, while a very considerable part is employed in accelerating the train and afterward wasted by braking. I have calculated the amount of energy which can be practically saved under the conditions of local and express traffic on the New York underground road and find that with motors of ordinary efficiency about 45% can be returned. If storage batteries are used in connection with the central stations, the batteries being located along the line, a uniform load can be thrown on the stations, and their capacity may be reduced to almost one-half as compared with a system in which the energy is not returned; thus greatly decreasing both the expense of installation and of operation. As it is possible at present to obtain batteries with a rapid discharge rate at very reasonable prices and with a guarantee for repairs that places them well within the limit of commercial calculations, a system of this kind offers some advantages over any other system that could be applied to the operation of the underground road. An alternating current would hardly be economical for this work, as it precludes the possibility of returning the energy to the line, and as the variable speed required makes it uneconomical as compared with the direct current system using, say, four motors with series parallel control. In the case above cited, shunt motors would be used, and it would be possible to get a contact with the line that could not under any circumstances be broken. The case of the elevated roads is very similar to the one I have cited except that in existing structures shorter trains would be used, and the cost of equipment for a given number of cars would be somewhat greater.

Baltimore has been the pioneer in almost every branch of transportation. In ocean service, the record of the Baltimore clipper is a tradition of our maritime supremacy. The Baltimore and Ohio Railroad was the pioneer steam road. An electric road from Baltimore to Hampden built in 1885 gives us a right to boast of our pioneer work in electrical tramways. The immense locomotive for the Baltimore Belt Line Tunnel is the first instance of the direct displacement of steam by electricity, and the line over which it is to be operated is the first through steam line to be equipped electrically. The Baltimore and Columbia Railway Co. owns in Washington the Eckington and Soldiers' Home Railroad and the Belt Line Railroads, and has franchises for extensive additions to their present mileage. In Baltimore they are constructing a road in the city and beyond it to Ellicott City, and they have also purchased a steam line running from Baltimore to Catonsville. They have rights of way from the terminus of their Baltimore lines to the lines they own and are preparing to build in the District of Columbia. The problem offered is not a simple one, but it is one of the most attractive that can be presented to electrical engineers. Speeds of 60 miles per hour are to be used for the cars outside of the city limits, and within the city limits ordinary speed is to be employed. In the District of Columbia overhead trolley lines are not allowed, and some type of conduit will have to be employed. In fact there is presented almost every problem which must be solved if electricity is to displace steam in the future with the same rapidity that it has done in the past. Many high speed electric roads have been projected; a number of them occupying considerable space in the newspapers; but I think this road will be the first to solve the detailed problem of interurban rapid transit.

The last subject which I wish to take up is the electric plant for the Belt Line Tunnel of the Baltimore & Ohio Railroad. In this case there is no question of economy in the employment of the electrical locomotives, as the plant adds considerably to the

cost of operating the road. The Belt Line Tunnel runs beneath the city of Baltimore for a distance of one and one-quarter miles, then to the outskirts of town through open cuts and short tunnels. There is a grade of .8 of one per cent. over almost the entire length of the tunnel proper, while one-half mile beyond it there is a grade of 1½ per cent. Being in the middle of town it would have been difficult to have provided a satisfactory ventilating plant even supposing that ventilating plants had been successful in other localities, which is not the case. The managers of the B. & O. Railroad Co. wished to provide a satisfactory service, and considered a number of plans for drawing their trains through the tunnel without the annoyance due to smoke and gases. After careful consideration they concluded that electricity was the most satisfactory means to accomplish this, and the General Electric Co. was confident enough of its ability to successfully equip the road to make a contract with the B. & O. Co. to haul its trains over the Belt Line, the contract being dependent upon the successful operation of the plant. The total length of the line equipped is about three miles, the extension beyond the tunnel being for the purpose of assisting the freight locomotives to haul their trains up the 1½ per cent. grade on the line beyond the tunnel. There are to be three locomotives and it is calculated that the traffic can ordinarily be handled by two of them. The steam engines are not to be taken off the train, but hauled through the tunnel by the electric locomotive which switches off at the terminus of the line. To operate these machines, a station has been erected which contains 3,000 H. P. of electric generators, and an overhead line has been equipped to transmit the current to the locomotives. With respect to the station itself, there is little that is novel. There are four 750 H. P. Allis-Corliss engines directly coupled to generators of the same capacity, the generators having a voltage of 600 at no load and 700 at full load. The foundations have been partly erected for a fifth unit in case it is found necessary. The building also contains a lighting plant having a capacity for 400 arc lights and 4,000 16 C. P. incandescent lights. Provision has also been made for an extension to this lighting plant when the stations for the Belt Line are erected. There are two incandescent machines and one of them will be used to supply the 1,000 32 C. P. lamps which have been installed in the tunnel. Perhaps the most novel feature of the plant is the overhead structure that is employed. The conditions to be met were peculiarly difficult, and the ordinary underrunning trolley was considered impracticable. The tunnel is very low in places and the management of the road decided that the conductors could not be placed over the cars, but should be placed in the middle of the tunnel between the tracks. Outside of the tunnel the conductor is still between the tracks, but is elevated to a height of 22 feet, while inside of the tunnel it is only 17 feet from the top of the rail. The conductor consists of an iron trough made of two Z bars riveted to a cover plate 12 inches wide, leaving a slot one inch wide between the Z bars. In the tunnel this trough is supported from transverse channel bars secured to expansion bolts which are fastened in the top of the tunnel. There is a double insulation; one porcelain insulator being between the trough and the channel bars, and another between the channel bars and the expansion bolt. Outside the tunnel the trough is supported as follows: At distances of 150 feet light iron columns with cross trusses are erected, and between these trusses are hung catenaries supplied with a number of suspension bolts. Transverse channels similar to those used in the tunnel are fastened to these bolts, and the trough is fastened to the channels. The Z bars are made in lengths of 30 feet the opposite bars breaking joints with one another, the lengths being riveted together and then bonded with "Chicago" rail bonds. Suspended on the same transverse beams as the trough are three copper cables of 1,000,000 C. M. area which serve as feed wires and which are connected at intervals with the trough, there being of course one trough for each track. For the return circuit the tracks are bonded as in ordinary railroad work, there being cross bonds and at intervals connections with a copper cable of 1,000,000 C. M. area carried in a wooden trough between the tracks. The contact arrangement that it is to be used consists of a brass shoe travelling in the trough and connected with the locomotive by a flexible saw buck arrangement which has a very considerable range in every direction. The current is transmitted to the motors by a copper cable, and in case of the shoe sticking in the trough, a safety pin is arranged to break with any desired strain. Where switches are used there is a tongue worked by the lever which operates the track switch, and which serves to direct the shoe. This structure, although exceedingly massive and expensive promises to give an excellent contact at all times, and it requires no care from the motorman.

The locomotives are the most massive in the history of either steam or electrical transportation, and the weight, which amounts to 95 tons, is on eight driving wheels so that the full tractive power of the locomotive will be developed. On each axle there is sleeved a 6-pole motor, there being considerable play between the axle and the sleeve which latter is spring-supported from the frame. In this way any heavy blow due to irregularities in the track is taken through the springs, and the wear both of the track and the locomotive is reduced. On the armature shaft are projecting arms which move between lugs cast on the wheels, thus allowing the necessary relative motion between the axle and armature.

The situation in the Baltimore Belt Line plant is this: The station is completed and is being operated daily. One of the locomotives is on the ground set up and ready to run, and the overhead work is finished with the exception of a short length which was interfered with by a temporary bridge over a cut. The latter has been removed and the plant should be ready to run this week.

If this equipment proves successful it will open a limited but important field for the introduction of large electric locomotives. There are in the United States a number of tunnels whose operation is anything but satisfactory at present, which can be equipped as the Baltimore Tunnel is equipped. Several of them have the additional advantage that they are near the switching yards of the roads and the same plant could be used for hauling trains through the tunnels and for switching, and not only would the economy of the station be increased, but the substitution of electric for steam switching engines would result in a very considerable saving.

This is the last of the subjects that I proposed to consider. In this paper I have not indulged in prophesy nor have I imagined any apparatus or equipment which cannot be bought to-day in the open market. But to me it seems that the present is a crisis in the history of railroading. Up to the present the steam roads have ignored the competition of electric roads or they have fought them. To-day they cannot afford to do either. In a few years electric roads will have absorbed practically all of the local traffic and will begin to cut into through transportation. The steam roads cannot afford this and their only safety is to make of electricity an ally instead of an enemy, and this before it is too late.

The conclusions that I finally reach are these:

1st. The tendency of passenger transportation on the steam lines has been in the direction of the greatest electrical economy while the tendency of the freight transportation has been in the direction of the least electrical economy.

2nd. It will not pay any through line with considerable traffic, having two tracks, to equip their main tracks electrically.

3rd. With four track roads it will pay to equip all of the tracks electrically unless a considerable portion of the business is through passenger traffic.

4th. It will pay all the larger roads either to equip a number of their branch lines electrically, or to control competing electric lines.

5th. In order to remain on a dividend paying basis it is imperative that most of the two track lines either build additional tracks or control the electric railroads that parallel them.

6th. Believing that ultimately all of the traffic will be done by electricity, it is imperative that the managers of steam roads keep constantly in touch with electrical progress.

REORGANIZATION OF THE LONG ISLAND TRACTION SYSTEM.

Clinton L. Rossiter, assistant superintendent of the western division of the New York Central Railroad, has accepted the Presidency of the Brooklyn Heights Railroad, and took Mr. Lewis's place on July 1. These are the plans for the reorganization of the Long Island Traction Company, which holds the lease of the Brooklyn Heights road: The formation of a new company, which will assume the lease, assets, and liabilities of the old company; the formation of a new company with $20,000,000 common stock, to be exchanged for Long Island Traction stock on certain conditions; the issue of $6,000,000 of bonds to run ten years, and pay 6 per cent. interest; the levying of a 10 per cent. assessment on the stock of the Long Island Traction Company; the collateral notes to the amount of $1,800,000, which are mainly held by the Flower syndicate, to be taken up on Aug, 6, when the one year's option will expire; the guaranteeing by an underwriting syndicate to the new company the full payment of the assessment and full subscriptions to the stock.

A DENVER CAR.

One of our correspondents reports riding recently on a car at Denver, Col., which is making 280 miles a day, turns 16 right angled curves every 20 minutes, and has been on the line for months without repairs.

BOSTON WEST END EARNINGS.

West End Street Railway earnings for Saturday, Sunday and Monday June 15, 16 and 17 surpassed the record of any previous three consecutive days in the history of the company, and the earnings for June 17 exceeded the earnings of Memorial day, which were the largest in the history of the company. The earnings for the three days averaged $26,800, and were in detail as follows: Saturday, June 15, $28,400; Sunday, June 16, $22,100; Monday, June 17, $30,000.

THE GENERAL ELECTRIC CONDUIT SYSTEM ON THE LENOX AVE. LINE, NEW YORK.

FIG 3. *The Plough.*

The first practical electrical underground conduit railway in this country is now in operation and will this week be connected to the great cable system of the Metropolitan Traction Co. The public will then be able to travel from the Battery to 146th Street, with one transfer, from the cable car to the electric car, at W. 108th Street.

The Lenox Avenue line is a double track road, starting at the car house at 146th Street and running directly south to 116th Street, into which it turns and proceeds as far west as Manhattan Avenue. It turns there and runs as far south as 108th Street, along which it is carried to the junction of that street and Columbus Avenue. The power house is a temporary frame structure with a sheathing of corrugated sheet iron, located on 146th Street a few yards west of Lenox Avenue. The present power plant consists of two 650 H. P. engines and 400 K. W. generators. Steam is supplied from 2 Babcock and Wilcox water tube boilers, arranged in one battery. Each has a rated capacity of 250 H. P. furnishing steam at 120 pounds. The engines are horizontal cross-compound Allis-Corliss machines, which during the experimental trips are run non-condensing. All the steam piping is placed beneath the floor of the engine room. To each of the engines is coupled a General Electric 400 K. W. generator of standard construction but wound for 350 volts, instead of 500 volts as is the usual practice in railway work. This machine is placed between the high and low pressure sides of the engines.

From the generators the cables run beneath the switchboard to a subway, under the sidewalk on 146th Street extending as far as Lenox Avenue, where they are introduced into the five-inch iron pipes running parallel with the conduit. For the present the line will be operated directly from the power house, but the feed wires will probably be placed in the pipes and will be tapped into the conductor at the necessary points. This line will then be divided up into sections and its general operation thereby greatly facilitated.

The construction of the underground contact system is simplicity itself. The plough suspended from the car truck passes through the slot in the centre of the track and presses against the flat surfaces of two iron conductors running the entire length of the conduit. These conductors are placed each three inches on each side away from the centre of the slot, to avoid deleterious effects of any drip which would otherwise reach them, and are of channel iron four inches deep and thirty feet long. They are suspended from the ceiling of the conduit by means of insulators devised for this especial purpose, and are at a depth of thirteen inches below the conduit slot. Each conductor is sufficiently rigid to require suspension at the ends and

F. S. Pearson.

L. J. Hirt,

centres only, and the ends being located in the manholes and hand holes being placed at the centres, inspection and repairs are rendered comparatively easy. The conductors are bonded to each other by stranded copper wire securely riveted into the web of the metal.

Another form of suspension of the conductors was also tried for a length of about one hundred yards single track on 116th Street, between Lenox and Seventh Avenues. This is known as the pedestal method of support. At the manholes instead of insulators suspended from the ceiling of the conduit, the conductors are supported by a soapstone pillar. The channel bar conductors in this case are five inches deep and are set 12 inches below the slot. The soapstone pillars are provided with iron caps furnished with brackets to which the conductors are bolted, and continuous connection is secured by means of a bond of flat copper strips riveted to the webs. The soapstone blocks are set in iron bases erected in the manholes. It is understood that no more pedestals will be used.

Every twelfth manhole is connected with the power house by

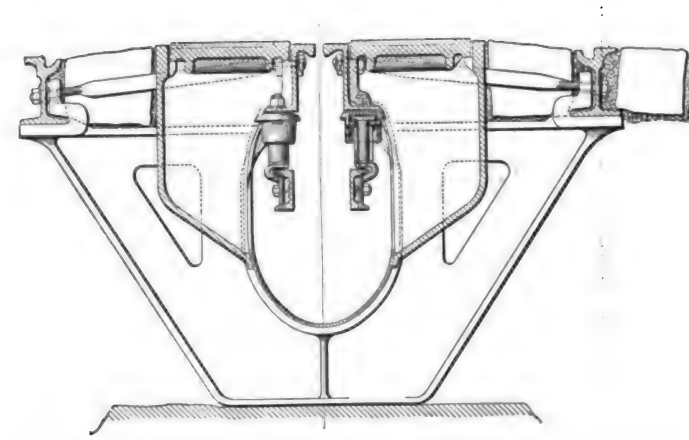

FIG. 1.—NEW YORK ELECTRICAL UNDERGROUND CONDUIT SYSTEM. SECTION OF CONDUIT—INSULATOR SUSPENSION.

telephone. Quick break switches are located at intervals in these manholes, in order that any section of the line may be cut out in case of trouble or accident. At the track switches each conductor is provided with a flaring nose to facilitate the entrance of the plough into the conductors. The manholes in which the insulators are placed are 4 feet 4 inches in depth, 4 feet in length and 14 feet 5½ inches in width, that is, the entire distance of the two tracks. They are constructed of brick with 8 inch walls that rest on concrete foundations. The floors are laid with 6 inches of concrete and are provided with drains for carrying off

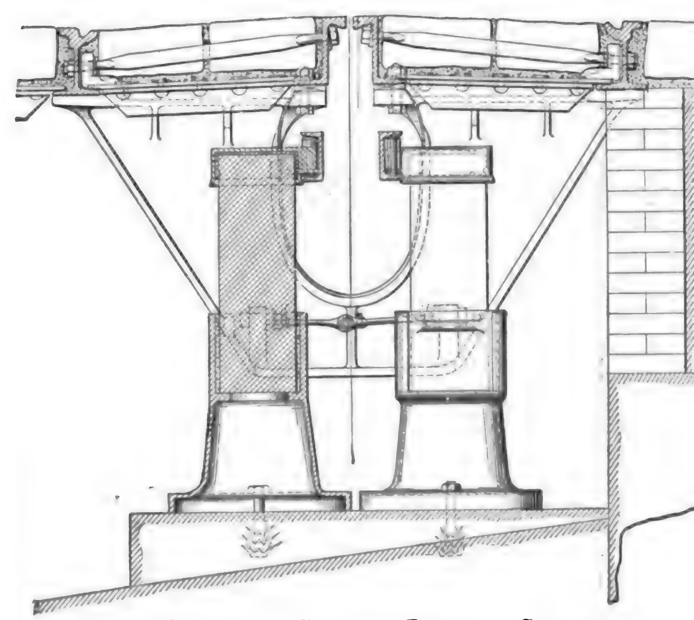

FIG. 2.—SECTION OF CONDUIT—PEDESTAL SUPPORT.

water. With this provision for drainage no trouble from water in the conduit will, it is believed, be experienced. The conduit was built along the grade of the street but with sufficient pitch to permit any water flowing into the conduit to find its way into the manholes, located every 30 feet, and from thence into the sewers.

The current does not return by means of the rails. Each conductor forms one side of the working circuit. The current merely rises on one side of the plough, passes through the controllers into the motors and after performing its duty returns by the other side to the opposite or negative conductor.

The plough or traveling contact arrangement is also essentially

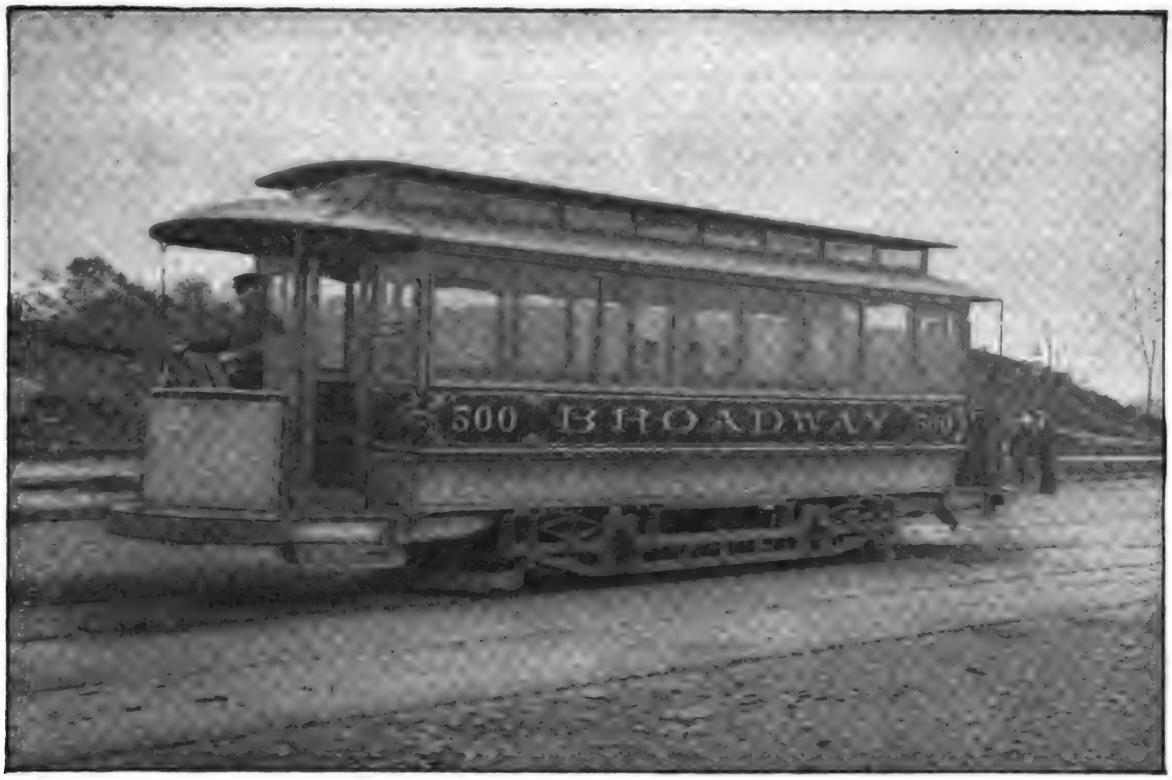

FIG. 4.—NEW YORK ELECTRICAL UNDERGROUND CONDUIT SYSTEM. THE CAR AND THE TRACK.

novel. It consists of two pieces of iron, one on each side of the plough, supported on spring leaves which cause them to press outwardly against the two conductors. The plough is suspended from a longitudinal bar bolted to cross beams set upon the track and is constructed of two sheets of steel laid each one upon a plate of fibre. The two sheets of fibre are then brought together enclosing strip copper conductors connected at the top to the motor cables, and at the bottom riveted to two other pieces of sheet steel. These run on each side of the plough and serve as supports for the hinges which carry the sliding contact pieces. A heavy sheet of fibre continues downward and serves to separate these contacts.

The motors employed are the standard General Electric 800 machines, handled by "K²" controllers. The cars which are used on the line were constructed by the John Stephenson Company and are mounted on standard cable trucks constructed by the Peckham Motor Truck and Wheel Co. They resemble those used on the Broadway line. The cars are lighted by nine incandescent lamps arranged in groups of three each. A car barn similar in construction to the power house has been built at the

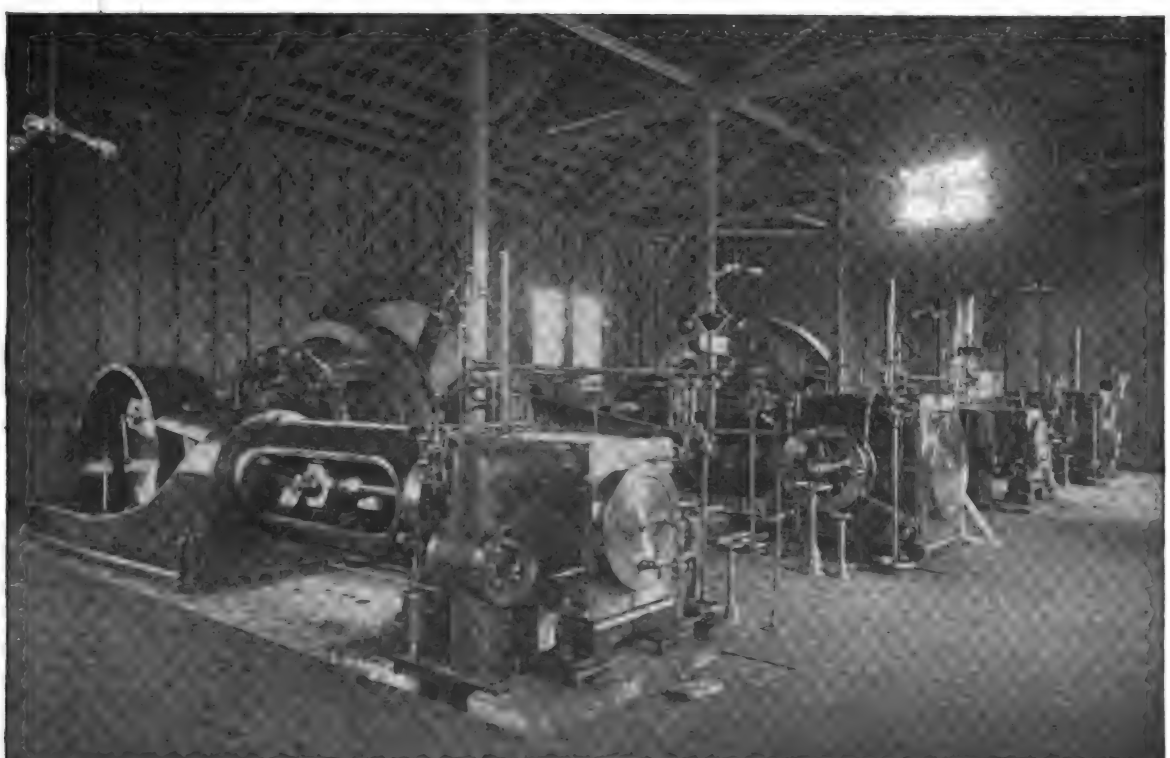

FIG. 5.—NEW YORK ELECTRICAL UNDERGROUND CONDUIT SYSTEM. INTERIOR OF POWER HOUSE.

corner of 146th street and Lenox avenue. The building is provided with four tracks and has a storage capacity for about twenty cars. The tracks are provided with pits for the examination of the trolleys and motors.

It is stated that in case the operation of the electric conduit system proves successful, the power will be increased by the addition of three direct connected units of 1,500 H. P. each, making the total capacity of the station 5,000 H. P. The present temporary structure will be replaced by a handsome brick building for a power plant, car house and repair shops. It will be built on the west side of Lenox Avenue, on which it will extend 200 feet, and its depth will be 550 feet. It will be two stories in height, constructed of a steel skeleton inclosing brick walls and will be fireproof. The car house will have a capacity for about 350 cars. The office of the receivers and starters, as well as the waiting room for conductors and motormen, will be located at the corner of 146th Street. The car house will be provided with two large elevators, which will be operated by electricity. Ample provision has been made on the ground floor for repair shops and rooms for the engineers and firemen. The superintendent's office and a large reading room for the employés will be arranged on the second floor. In the tower on the third floor accommodations will be provided for the electricians of the station.

THE ELECTRICAL EQUIPMENT OF THE NANTASKET BEACH ROAD.

The first direct application of electricity to the steam railroad has been made on the Nantasket Beach branch of the New York, New Haven and Hartford Railroad, and the first runs as already described in THE ELECTRICAL ENGINEER have proved remarkably successful. The line was almost exclusively operated by the electric trains on the 30th of June. The Nantasket Beach railroad extends from the Old Colony House Station, Boston, as far as the Pemberton Station, a little beyond Hull, at the extremity of the narrow Peninsula, one side of which is known as Nantasket Beach. The length of the road is 6.91 miles and of this there are 4.4 miles of curves in about 20 curves, the sharpest being one of 10 degrees. The line is almost level, the only grade, one of about 34 feet to the mile, occurring within the first mile out from the Old Colony House Station, the name of which has been recently changed to Nantasket Beach Junction. The track is laid in 70 pound rails, with 15 feet space between the track centres, and the ballast is of stone. Each joint is bonded with a flexible No. 0000 bond of stranded copper, seven inches long, riveted into the flange of the rail. The line traverses two trestles and one plate girder bridge, the latter located near the Stony Beach Station. Engineering difficulties were, of course, met with. Six thousand yards of rock ledge were taken out near the Old Colony House Station, and between Stony Beach and the terminal station at Pemberton a heavy retaining stone wall had to be built on the shore side of the track. On the sea side of the track, a second retaining stone wall, about three-quarters of a mile long and varying in height from eight to fifteen feet, and in thickness from ten to fifteen feet, has been constructed to take the place of a trestle.

There are at present ten stations on the line, but other stations will be built to allow of stops at about every quarter of a mile. At Pemberton, the station consists of two 500 feet roofed platforms between the tracks, and a similar length of platform outside the tracks.

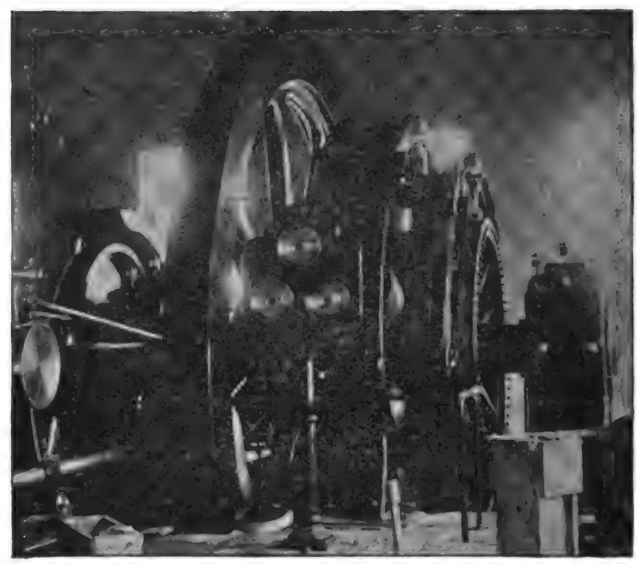
The overhead trolley line is carried upon poles set between the tracks. These poles are of southern pine, thirty feet long, twelve inches by fourteen inches at the butt, and ten inches by ten inches at the head; and are set at intervals of sixty and seventy feet on the curves and ninety feet on the straight track. At the cross overs the posts are 180 feet apart, and side posts are used carrying a light iron truss over the track. On the trestles they are carried down through the trestle floors and are bolted to cross timbers fastened to the piles. The top of each pole is fitted with a cast-iron grooved cap, the grooves of which carry the six bare copper feeder cables, each of which has a cross section of 500,000 circular mils and weighs 1.56 pounds to the foot; each consists of 49 No. 10 gauge wires being laid in seven wires of seven strands each. The poles are set in wooden boxes filled with concrete, and are set towards the inside track on curves to throw the trolley wire over, and thus provide for the angle of the trolley pole caused by the 4.8 inches elevation of the outer rail.

The trolley wire is of pear shape in cross section. It weighs one pound per foot and has a cross sectional area of 330,000 circular mils. The lower surface is almost flat, and provides a large contact surface for the trolley wheel. This form has been given to the wire to permit of a more perfect attachment to the hangers and to prevent the trolley from jumping when passing them.

The brackets, of two angle irons, are bolted across the centre poles and bent and bolted together at the ends. They are kept in position by an iron truss running through the cap. Each hanger is a double hanger and gives an excellent support for the wire. In stringing the trolley wires and setting the poles, steam locomotives were employed, and by their use the work of months was shortened into weeks. Indeed, the entire installation is an example of extremely rapid work.

The power house, which will be known in history as "Power Station No. 1," of the New York, New Haven & Hartford Railroad, is located 5,900 feet from the junction station. It is a brick station with stone trimming erected on a rock foundation, and has a slate roof on steel roof trusses. It is 79 feet by 100 feet inside the walls and is divided by a 24-inch brick partition into engine room and boiler room, each 79 feet by 52 feet. The power house proper is provided with a travelling crane of 53 feet span, the dividing walls being reduced in thickness to accommodate this length of span. The boiler room is equipped with two batteries of 4 boilers each. The boilers are of the horizontal type and are 72 inches in diameter, 19 feet long, with 140 three inch tubes. Each boiler has a nominal rating of 185 H. P. but will generate 350 H. P. at 125 pounds steam pressure. The flues enter a 115-foot circular brick stack, 13 feet in diameter at the base. This stack was put up in 11 days and 6 hours.

The engines are two in number, and are horizontal tandem compound Greene engines erected by the Providence (R. I.) Steam Engine Company. The shafts are 18 inches in diameter and carry fly wheels 18 feet in diameter, each weighing 32 tons.



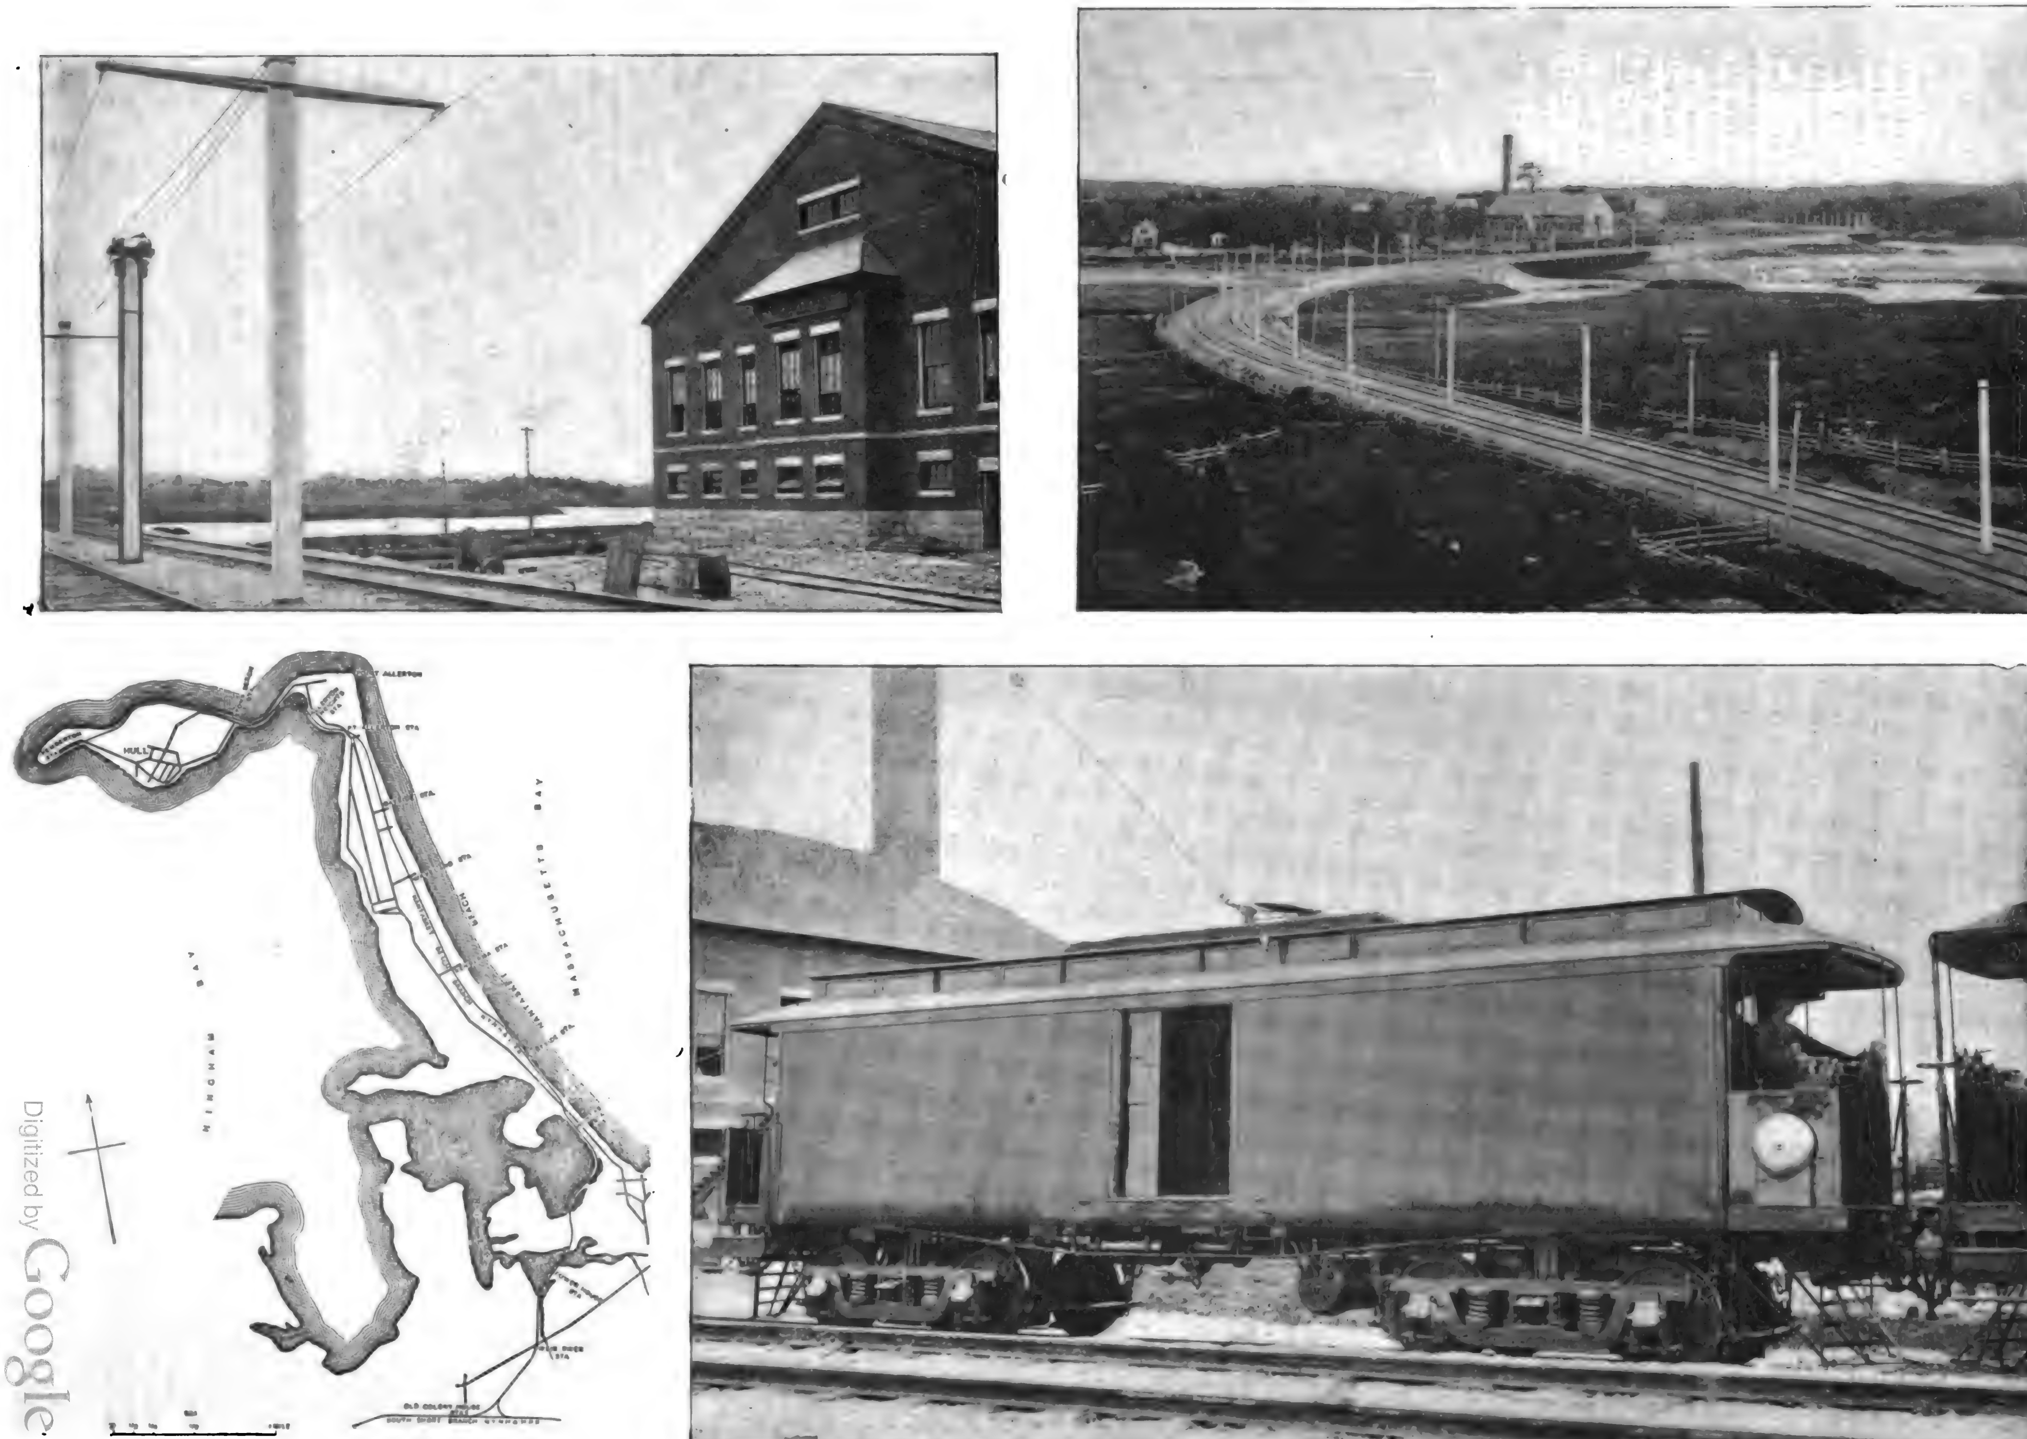
INTERIOR OF POWER HOUSE SHOWING GENERATOR, NANTASKET BEACH ROAD.

The engines can be operated non-condensing or condensing, and are furnished with automatic safety stops and steam closing mechanism.

The generators are direct connected General Electric 10 pole machines having the armature spider keyed to the engine shafts. They are wound for a pressure of 600 volts at no load and 700 volts at full load, and are rated at 500 kilowatts at 100 revolutions per minute. The fields are of cast steel and the armatures are of the "Iron Clad" type, each winding being insulated and then imbedded in an insulated slot in the laminated iron armature body. The ten brushes are all operated simultaneously by a hand-wheel, and are arranged to secure the most perfect contact with the commutator.

The switchboard is placed in front of the engines, and is built up of two standard G. E. generator panels, set one upon each side of a third panel, carrying a form "G" recording watt-meter, showing the entire out-put of the station. Each generator panel carries a "K" automatic circuit breaker and the usual indicating and measuring instruments and switches for the power as well as the lighting circuits. From the switchboard the current passes along a lead covered cable, set in a 3½ inch drain pipe in concrete to a junction box at the foot of the nearest pole, up which it is carried in an iron pipe to the longitudinal feeder.

The motor cars are of two types—the closed and the open. The closed cars are heavy baggage cars, and four are already equipped for service. The open cars are sixteen reversible bench cars, and six are now receiving their equipment. The open cars resemble the familiar city trolley car, but have a flight of three continuous steps or foot boards. The closed motor cars are 42 feet long over all, and are built extra heavy, weighing each, when fully equipped, over 30 tons. Two of the four ordered will have two motors on one truck, while



Nantasket Beach Railroad; *Showing Map of Road, Power House, Line and Car.*

the two others will have four motors, two on each of the two trucks. The open motor cars will be two motor cars. The motors used are the "General Electric 2,000" machines especially designed for heavy work, and are similar to those in successful use on the Metropolitan Elevated Railway in Chicago. They are watertight and fireproof. The drawbar pull of the two-motor motor cars is 4,000 pounds; that of the four-motor motor cars 8,000 pounds, the motors being 100 H. P. each, or 2,000 pounds horizontal drawbar pull through a 33-inch wheel. The current is brought to the motors from the trolley wires by means of a trolley provided with a wheel having an extra deep channel, through a General Electric series parallel controller, set up on the right hand side of the platform. This controller is known as type "L" and is somewhat larger than the "K²." It embraces the magnetic blow-out principle and all the other familiar features of the "K²." The resistances are suspended beneath the car. Two controllers go to each car.

Immediately to the left of the controller is the air brake handle. The compressed air for the brakes and whistle is furnished by an oscillating cylinder air compressor operated by an electric motor, which is controlled by a special automatic rheostat which regulates the action of the motor in accordance with the pressure in the tanks. A magnetic cut-out is also provided for the air compressor motor. In the case of the closed cars the air pump is set just within the door; in the open cars it stands on the platform to the extreme left of the motorman.

Behind the motor man and just under the hood is the car cut-out, which in this case is an automatic circuit breaker similar in type to that used on the generator panels in the station. Two fifteen inch gongs are furnished to each car and are rung by the foot, and on one side near the centre of the car on the roof is a chime whistle operated by compressed air. The open cars are lighted by eighteen incandescent lamps, and the baggage cars by six. Each motor has a small pilot or cow-catcher placed beneath the platform. A feature of the line construction is the system of interlocking switches by means of which the overhead switch is thrown at the same time as the track switch.

The trains will be run as accommodation or express, the express trains consisting of a baggage motor car with open trailers, the accommodation facilities being furnished by single motor cars. The traction weight of the baggage cars will be increased by the baggage they will carry, and the light trains should be operated without difficulty. At Pemberton station the cars will run with the baggage car at the head. The motor car will then uncouple, switch and run back to the head of the train, the motorman changing platforms.

Credit is not only due to the New York, New Haven & Hartford people for their courage in essaying the new method but also to the men who have developed the machinery to enable them to carry it to a successful conclusion. Everything has been done upon the personal initiative of the President of the road, Mr. Chas. P. Clark. The electrical installation was effected on the plans laid out by Col. N. H. Heft, who personally supervised the work.

The tests made on this line are of considerable interest. The first showed that the motor car alone or with a small load could run at a higher speed than that attained by ordinary express locomotives, and maintain the speed without difficulty, and this without apparent effort. Subsequent tests were made with the locomotive or motor car as a freight hauler and not less than fifteen heavily loaded freight cars were easily moved and carried along the line at a high rate of speed. So far everything was satisfactory.

The crucial test was made on the 27th June when under Division Superintendent J. C. Sanborn's care a select company comprising nearly all the division superintendents and engineers of the New York, New Haven and Hartford R. R. and a few newspaper men were taken over the line. A special train of two passenger cars was made up and hauled as far as Nantasket Beach Junction, by a steam locomotive, which was uncoupled at this point and its place taken by one of the two-motor motor baggage cars. The coupling was effected without shock, and the train moved off in the direction of the power house without jerking on the couplings and considerably more smoothly than would have been the case with a steam engine. At the Power House, the company were shown everything by Col. Heft, and evinced great interest. By this time Mr. J. C. Sanborn's surprise was ready. A call brought the guests to the windows of the power house, in time to see a long train consisting of a motor car, about thirty gravel cars, fully loaded, and a brakemen's van, go flying by at 40 miles an hour in the direction of Nantasket Beach. After the inspection of the Power Station, the company reembarked and Col. Heft stationed himself at the controller. The gong clanged, and the whistle shrieked, and in a few moments the train of three cars swept at 40 miles an hour in a blinding rain storm towards Pemberton Station. On the return journey Col. Heft threw over the handle of the controller when the train came to the straight stretches, and the motors responded in a quiet effective way, sending the train whirling along down the wet track at a speed of over 50 miles an hour. The line was opened for regular passenger traffic with the electric car last Sunday.

TELEPHONY.

THE PITTSBURGH MEETING OF THE INDEPENDENT TELEPHONE MANUFACTURERS.

In accordance with the announcements issued, the telephone manufacturers in opposition to the American Bell Telephone Company, held their meeting at Pittsburgh on June 24, at the Hotel Duquesne. The main purpose of the convention was to perfect the organization that was formed in Chicago several weeks ago. Plans for the operation of the independent manufacturers were formulated in secret session, and an arrangement to more closely combine the interests of all was entered into. The independent manufacturers at the convention represented a capitalization of about $30,000,000. James E. Keelyn, president of the Western Telephone Construction Company, and also president of the organization, was present as the principal and active promoter of the organization.

The other independent manufacturers present were P. C. Burns, of the American Electric Telephone Company, of Kokomo, Ind.; Stanley S. Stout, of Chicago, attorney for the association; William Dillon, of the Indianapolis Electric Company, of Indianapolis, Ind.; H. T. Johnson, of the Manhattan Electrical Supply Company, New York; A. F. Stanley, of Stanley & Patterson, telephone manufacturers, of New York; A. H. Chadbourne, general manager of the United States Telephone Construction Company, of Philadelphia; Charles E. Blake, of the National Telephone Manufacturing Company, of Boston; W. H. Yerkes, Washington; E. S. Wallace, Columbia Telephone Company, New York; L. L. Levy, Anthony Telephone Company, Cincinnati; J. R. Johnson, Viaduct Mfg. Company, Baltimore; F. Harrington, Union Electric Company, Cleveland; J. G. Ihmsen, Keystone Telephone Company, Pittsburgh. It is understood that about 40 manufacturers have given their adhesion to this movement. The name of the Telephone Protective Association of America will be maintained, and all independent telephone interests are invited to coöperate. It is proposed to organize State associations on the lines of that in Ohio, and to insist on long distance rights over the Bell lines under the common carrier laws.

The Association has completed its organization as follows:—President, J. E. Keelyn, Chicago; First Vice-president, J. R Johnson, Baltimore; Second Vice-president, S. J. Turnbridge, Utica; Third Vice-president, Judge E. S. Wallace, New York; Fourth Vice-president, J. G. Ihmsen, Pittsburg; Fifth Vice-president, L. L. Levy, Cincinnati; Secretary, Paul Bossart, Minneapolis; Treasurer, P. C. Burns, Kokomo, Ind. The Board of Directors is composed of the Executive Committee: J. E. Keelyn, J. R. Johnson and S. J. Turnbridge.

Among the Directors elected are Messrs. E. B. Seeley, of E. B. Seeley & Co., and M. Kuhn, of the Clamond Telephone Co., Philadelphia.

The delegates were entertained while in Pittsburgh by the Solar Carbon & Mfg. Co. of Pittsburgh, which company was represented by Mr. F. Laughlin and son, who gave them a pleasant drive around the suburbs, including an inspection of the beautiful Carnegie Library. While the attendance was smaller than had been hoped for, the feeling was hopeful, and there were many indications of activity.

It is stated that the opposition companies have already about 100,000 instruments installed throughout the country.

NEW YORK TELEPHONE DESK CONNECTION.

The Metropolitan Telephone & Telegraph Co., 18 Cortlandt street, is now offering to give private line telephone service for $100 per year. It is also offering a nickel plated desk telephone, on the line with the main station, at $36 for a flat rate exchange station; $24 for a message rate station, and $24 for a private line station. The company claims to have over 2500 subscribers now on the message rate plan.

TELEPHONE TRAIN DISPATCHING.

Mr. J. C. Henry, who is now living in Colorado, writes us: "While in Denver recently I examined the telephone train dispatching system in use by the tramway company. The dispatcher keeps a train sheet and receives reports from the conductors at the terminals of the different routes. I overheard him, for instance, give the following instructions: 'Hurry up; you are fifteen seconds late, stop at —— for mail.' I am an old train dispatcher, having spent years in worrying with trains that were hours and sometimes days late, and these orders by telephone made me feel like a fossil aroused in the Bellamy ages."

DUBUQUE, IA.—The city council has issued its order that the Bell Telephone Company shall permit the Star Electric Company to use the poles of the former on Highland place.

NEW "M. & B." TELEPHONIC APPARATUS FOR EXCHANGE WORK.

An interesting exhibition of the M. & B. Telephone was given in Rooms 450 and 451 of the Bullitt Building, Philadelphia, on Wednesday, June 26th. The United States Telephone Construction Co. who control the sale of the M. & B. Telephone, and whose offices are in the Bullitt Building have had so many applications for exchange plants, and so many people were desirous of seeing their telephones in operation, that they fitted up a suite of offices in which they have a full line of their various types of telephones displayed, and connections made to several outside points. In conjunction with them the Gould-Smith switchboard was displayed, which is manufactured by the Eastern Electrical Manufacturing Co. The United States Telephone Construction Co. claim to have the only non-infringing battery transmitter. It has

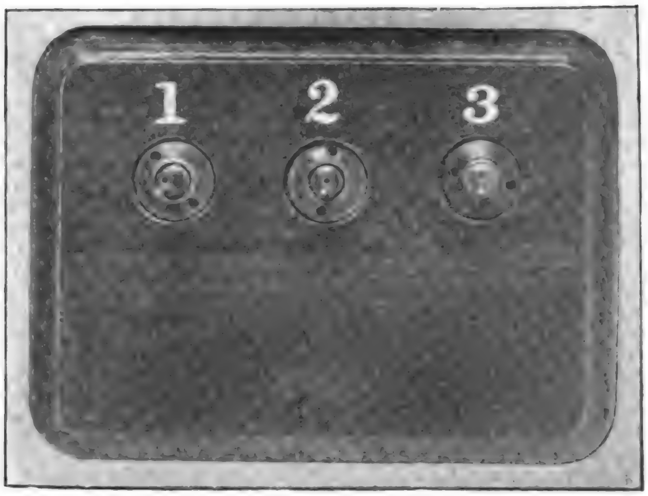


FIG. 1.—GOULD SMITH TELEPHONE SWITCH BOARD.

been described before in previous issues of THE ELECTRICAL ENGINEER, but it will not be out of place to speak of its mode of operation again. The construction of the transmitter is very simple, consisting of a carbon ball resting in a metallic run-way and a small carbon point held in an aluminum cup on a mica diaphragm. At every pulsation of the diaphragm a clean break is made between the electrodes, so that it is claimed that they in no way can be interfered with by the Berliner patent, which is supposed to cover all forms of battery transmitters in which the electrodes are in constant contact. Amongst other forms shown was their new Style D, Fig. 2, which is very compact and contains the battery and transmitter all in one box, together with the magneto call bell. Models were shown which demonstrated that the ball did recede from the point, making a clean break, proving that the electrodes are separated in ordinary conversation. The United States Telephone Construction Co. are prepared to supply all apparatus necessary to put in a complete exchange, which they claim to be absolutely non-infringing.

The switch board shown, manufactured under the Gould-Smith patents, contains a good many interesting features, full illustrations of which are herewith presented. The board is very compact, 100 subscribers being grouped in a space of only 18 inches square. It is stated that there are no infringing devices used on the board, and there were none which were apparent to the ordinary observer. There are no drops, no clearing-out devices, and no lightning arresters are used, because they are not necessary. In this board every subscriber has his own plug and cord, so that half the subscribers can be talking with the other half at one time. In other words, all subscribers can be talking simultaneously, which, it is asserted, is not true of any other board now in existence. A very interesting test was made showing that electric light wires and lightning could not burn out the board. A 110-volt current, which was the only one obtainable in the building, was repeatedly turned on the terminals, which automatically acted, and took off the "ground," thus preventing damage. It is said that in actual working, boards built on this principle have been struck by lightning, and that an arc current of 2000 volts has also been turned on without damaging the board, the reason being that the automatic action releases the cord and cuts off the ground connection so that the in-coming current must find some other means of outlet. In view of the recent patent decision it is certainly very interesting to see a complete system, operative in all its parts, yet designed with the express purpose of relieving its owners and users of all worry and anxiety on the score of infringement.

Fig. 1, herewith represents the appearance of the front of the Gould-Smith switch board with three subscribers' terminals in view. It will be seen that there are no drops or clearing-out devices of any kind. Unlike other boards, each subscriber has his own cord and plug. When a subscriber rings up central the automatic action releases his plug, and it springs forward towards the operator with a sharp click, taking the position shown in Fig. 3. The operator puts her finger to the terminal and pushes it back, at the same time asking "What number?" This operation is so quick, that the subscriber scarcely has time to put the receiver to his ear.

Fig. 4 shows that subscriber No. 1 has been connected to No. 2. The operator pulls out the plug of No. 1, inserts it in the end of plug No. 2, and forces them both back; they are now automatically locked. At the same time, the operator presses her foot on the pedal which rings the called subscriber, so that only a few seconds elapse between the subscriber's ring and the ringing up and connecting of the called subscriber with the one calling. As soon as the connection is established the operator cannot listen to, or hear, any of the conversation, nor can she disconnect the subscribers until they are through talking and themselves ring off.

Fig. 5 shows the same connection as No. 3 after the subscriber has rung off. It will be seen that the two plugs which are connected, are both automatically ejected upon the subscriber ringing off. The same action which forces these plugs automatically from the board takes place if an arc light wire, or any other wire carrying a heavy current comes in contact with the telephone wires, so that every terminal is its own lightning arrester. It is impossible for high potential currents to injure this board, as the instant the current reaches the coil, the armature is attracted releasing the automatic action, and the line is opened.

To sum up the particular features of this board differing from others in common use, the following advantages are claimed: No drops or aprons are used, no weights, no spring jacks or sockets. No test circuit is required, no key board of any kind, no extra clearing-out drops, no supplementary lightning arresters. In addition to this, great speed is claimed for the board, as only three motions are necessary to make the connection. The board is very compact, which is always a great advantage.

FIG. 2.—M. & B. TELEPHONE TRANSMITTER, STYLE "D."

Another point is that the operator's time is not taken up making daily tests, as every subscriber tests his own line when he calls up central. In short, the board marks a distinct new departure in central exchange work; and is obviously a great advance on many existing methods.

A cut of the Gould-Smith Toll Line board for connecting outlying or distant towns is also shown in Fig. 6. In this board no plugs, cords or sockets are employed. This also is a metallic circuit board, the connections being made by a rubbing spring contact.

CONTENTS.

THE INSTITUTE MEETING.

If the number of attendants is any index of the success of a meeting, then the Twelfth General Meeting of the American Institute of Electrical Engineers held last week at Niagara Falls must be considered the most successful thus far in the history of that body. The selection of the place for this year's meeting proved to be eminently judicious, and while the natural beauties of Niagara no doubt acted as an attraction for many, the inference is fair that the great electric power development now undergoing its first test, and the desire to inspect and study it on the ground, probably acted as the reason that brought nearly two hundred members and their friends to Niagara. Nor did their expectations remain unfilled. Thanks to the courtesy of the Cataract Construction Co., the Institute was the first body admitted as such to the great power house, and its members were thus afforded an opportunity of judging for themselves of a work about which so much has been written and which has given rise to not a little controversy. The first impression which the sight of the 5,000 H. P. generators made upon the majority may be said to have been disappointing,—disappointing in the sense that there was so little to see. One is so accustomed to consider a 5,000 H. P. plant as an aggregation of boilers, engines, dynamos, pumps, feedwater heaters,—not to speak of the coal pile,—that the sight of a generator of such a capacity occupying a space barely 12 feet square and 13 feet high is apt to give one a nervous shock. It is true that the prime mover in the present case was not in view, being at a depth of 140 feet below in the pit, but even if both generator and turbine were placed side by side their simplicity and the space occupied by them, would be out of all proportion to that of a corresponding steam plant

The Institute was fortunate in eliciting at this meeting an authentic, though brief, history of the methods finally adopted in carrying out the work at Niagara, Dr. Sellers and Mr Stillwell giving, respectively, the details of the mechanical and civil engineering and the electrical engineering parts of the work. But the complete history of this justly celebrated work, we think, has still to be written, if we may judge from the highly interesting communication which we print this week from Prof. Henry A. Rowland, who for a time acted in an advisory capacity to the Cataract Co. While called forth by a personal difference with Prof. Forbes, this communication is none the less valuable as a contribution to the history of the evolution of Niagara's electrical power, and engenders the hope that we may soon be placed in possession of all the facts in the case, which now necessarily lie hidden in the reports in the hands of the Company. It is, of course, too much to expect the publication of the latter pending the full trial of the completed plant and a time test of the methods adopted; but these impediments will, we hope, be soon removed.

It may be noted, in passing, that before the Institute members had all left on Friday last, the work of actual transmission of power began, no less than 2,000 H. P. being sent to the Pittsburgh Reduction plant (already described in these pages), a distance of about three-quarters of a mile.

Particularly apropos of the time and place of the meeting was Dr. Emery's paper on "The Cost of Steam Power." We have of late had so much wild talk on this question, especially in the vicinity of Buffalo, that a calm consideration of the subject by a competent and recognized authority must go far towards putting the quietus on many of the absurd statements and figures which have gained currency. If we read Dr. Emery's figures correctly, a 20,000 H. P. plant of the most modern construction cannot compete in cost of power delivered *at the engine shaft* with the price of electric power delivered *at the motor terminals*, as actually contracted for by the Niagara Falls

Power Co. In other words we must add to Dr. Emery's figures the cost, interest, depreciation, etc., of the electrical machinery necessary to distribute the power of the steam engines in order to make the comparison complete; and when this is done, the disparity in favor of the Niagara power becomes still more pronounced. This remark is, of course, not intended as a criticism on Dr. Emery's paper, but we have thought it well to point out the fact in order to set the matter in a clearer light before those who have so strenuously insisted on the low cost of steam power as against the exceptionally favorable and very rare conditions obtaining at Niagara.

Considering the extent of electric railroading in the United States it is somewhat surprising that the meeting elicited but a single paper bearing on this topic, that of President Duncan's; but though standing alone it contains sufficient meat to set steam railroad managers thinking for some time to come. Of the conclusions reached by Dr Duncan, the third and fifth appear to us as describing the situation as it exists at present. For the steam roads to ignore electricity is simply fatuous, and when the figures for through and local passenger traffic as given in Dr. Duncan's paper are compared, it is seen that there can be but one answer to the question of the future operation of railways. As if to accentuate the force of Dr. Duncan's arguments, the announcement is made that the last of the big cable lines in Philadelphia are being abandoned to give place to the trolley. Surely it must be more than mere sentiment that dictates the abandonment of millions of dollars invested in machinery and cable conduits and the investing of large additional sums in new electric construction; and what cable roads have done steam roads will yet do with even greater propriety.

TELEPHONE UNCERTAINTIES.

Last week the organization of the "independent" telephone manufacturers was accomplished at Pittsburgh, and it now remains to be seen what the body will be able to accomplish. To some extent the association appears wanting in strength, and the meeting itself was somewhat of a disappointment; but no one can question the wisdom of Mr. Keelyn in pushing through his plan for united action against an enemy that has the vantage ground and so many of the sinews of war. The next move on either side will be awaited with interest; meantime the telephone industry is in rapid expansion. Indeed, in view of the long business depression, it is amazing that the activity should be so great. It merely shows how inadequately the wants of the public in general have so far been met.

But if the rally at Pittsburgh of the new forces was rather disappointing, the entrance of new factors into the field of telephonic contest supplies food for encouragement and hope as to the steady growth of an industry long repressed. As times improve new capital will find its way in, with more and more of specialization of product. It will not all be exchange work; nor will it all be interior work. The wants of the rural districts alone constitute an enormous market that has not been touched; while railroads, street railways, mines, ranches, and special lines all need attention. The long distance work presents, perhaps, the most important problem; for here would appear to lie the area for the next "irrepressible conflict." It is obvious that telegraph and telephone companies cannot long exist together on the present footing; and even now the rumors are bruited of trouble between the American Bell and Western Union, and of alliance between the Postal Telegraph and Standard Telephone interests. These reports are denied, of course, and even the bases for them are often obviously wrong; but the underlying instinct of the public that things cannot long endure as they are, with the telegraph slowly succumbing to the telephone, is entirely right. There must be an early re-adjustment. For example, the Bell-Western Union contract runs out next year, when it is hardly to be expected that the telegraph company will be satisfied with half a million dollars annually for sitting still and seeing its revenues sapped.

CONDUIT TRACTION IN NEW YORK CITY.

We illustrate this week the conduit system installed by the General Electric Co. on Lenox Avenue in this city. The road was visited and inspected recently by the New York Electrical Society, and the general opinion undoubtedly was that the working of the system was very satisfactory. Such is the view also formed by ourselves from constant observation during the past month, but it would be premature to make up one's mind until the road has gone through the ordeal of winter. Improvements of more or less value are in quiet progress, however, and by Fall the road should be ready for the test to be given it. Fortunately the trial will be made under the supervision of Messrs. Pearson and Hirt, both of whom are thoroughly well informed on electric traction and are entirely friendly to the use of electricity. It will be noticed that already the pedestal support of the conductor in the conduit has been exchanged for a suspension method, while the plough itself has been gradually modified, the better to meet the conditions.

What is known as the Love conduit system is also soon to have a trial in the upper part of the city, and from the interest shown we can only believe that the successful demonstration of conduit methods in the higher part of New York City will lead to an insistent demand for their adoption on a great many of the lines uptown and down.

POLITICS AND ELECTRICITY.

Why there should be any politics in the appointment of an electrical subway commissioner it is hard to see; but, granted there must be politics, it is equally hard to see why electrical engineers are not selected for such positions. The question is one we are now looking at from a local, New York, point of view, but it is one that crops up all the time all over the country. In New York, Mayor Strong has just removed Mr. Amos J. Cummings from a Commissionership of the Board of Electrical Control on the alleged ground that he is a Tammany man; and he has filled the vacancy with a Mr. T. L. Hamilton, apparently for no other reason than that he is a "Platt man," and friend of a gentleman popularly known as the "wicked Gibbs." Now Mr. Hamilton may be a worthy, respectable man, though his affiliations lead us into a little doubt on the subject. But we do not think that he would be proven any better, as a man, than Mr. Cummings; and if the latter is removed on political grounds, why replace him by another politician?

Had Mr. Cummings been removed because he was not an electrical expert, we should have been glad to approve the Mayor's action heartily; but as things are, the change is a discredit to a Mayor who came into office on a reform ticket, pledged to fill the offices without distinction of politics. Moreover, why did not Mr. Strong select an electrical engineer? We know that more than one good man was brought to his notice, quite capable of discharging the duties properly—which is more than can be said of a single subway commissioner yet appointed since the subway law went into effect.

The Board of Electrical Control is or should be an engineering body, just as the Board of Health is a medical body. While we do not insist that its every member should be an electrical expert, we do insist that at least one member should be an engineer, and that the Commissionerships are not mere political spoils, for the greediest retainers of unscrupulous leaders. Such events as this are, however, but mere casual samples of what would happen with full municipal control of every enterprise.

Letters to the Editor.

PROF. ROWLAND AND THE NIAGARA PLANS.

In the English journal, *Lightning*, sometime ago was published an interview with Prof. George Forbes which contains statements about my connection with the Cataract Construction Co., so far from the truth that I cannot allow them to pass without a brief statement.

In making this statement I am, of course, hampered by the necessity of only mentioning those facts which have, in various ways, become public property.

My first report was made to the company in 1889, not 1890, as Prof. Forbes states. In this report the questions submitted to me were very limited. Suffice it to say that I *did not* report against the alternating current system but said instead that it had a "great future before it," but that at that time it was not in a commercial state and, indeed, neither was the continuous current system, for such an enterprise. I advised the company to wait and study the problem for a time. This I regard even now as most excellent advice.

If Prof. Forbes, more than a year later, was able to report definitely in favor of the alternating current system I am not surprised after the immense strides made in the subject during the interval between our reports.

When called upon again in the summer of 1892, I found that the company were ready to decide upon their final plans, and that they wished my opinion principally upon the scheme devised by Professor Forbes himself. Thinking that I could readily agree with a gentleman who had examined all the systems of the world, I consented, thinking it all a mere form.

When, however, I came to examine the plans, I found that I could not agree and I would have gained peace and freedom from the most disagreeable experience of my life if I had done so. But I regarded it as cowardly to withdraw and, as I had agreed to give my opinion, I did so in words scientifically true and exact.

It is not to be supposed that I went into this enterprise as an electrical engineer to give advice on details, but only as an electrical expert to decide on the general system to be used and the company to carry it out. The Cataract Company knew that there were many, including Prof. Forbes, who were more familiar with details but they wished me to study the subject from a general standpoint and give them my judgment on it.

The main subject that I had to consider was Prof. Forbes' report to the company dated Sept. 16th, 1892, giving his final recommendations to the company.

As this report was handed to me confidentially I only feel at liberty to quote the final specifications as these have been made public by the action of the company in sending them to those who were to bid on the plant, as well as in other ways.

Specification.

"Each dynamo is to be of such size that it absorbs 5,000 H. P. of mechanical energy on the shaft. It is to be supported on a vertical shaft working in adjustable bearings; speed 250 revolutions per minute. The revolving parts of the dynamo must weigh not over 10 tons and must be perfectly balanced. The top bearing must be supported in a thoroughly substantial manner. The dynamo is to generate alternating currents with 8⅓ complete periods per second. The armature coils to consist of 8 coils, 4 in what we may call phase A, and 4 in phase B, which is in quadrature with phase A. The 4 coils in either of these circuits can be connected in series or in parallel or 2 in series and 2 in parallel, thus giving at will either 2,500, 5,000 or 10,000 volts.

"The armature must have no revolving iron. The conductors revolving between pole faces are to be vertical and are to be driven and supported by driving pieces rigidly connected with the shaft and so designed that Foucault currents do not unduly heat them. The losses due to copper resistance, Foucault currents and hysteresis, are not to exceed 2 per cent. of the maximum output. Rises in temperature of the armature conductors not to exceed 80 degrees Fahrenheit. Insulation throughout to be of mica, and must be subjected, through mechanical strain or changes of temperature, to no shearing stress."

These recommendations can be analyzed as follows:

1st. The two-phase alternating system was to be used.

2nd. Very light revolving parts, *not exceeding ten tons in weight*, to be used.

3rd. No iron to be used in the armature, but only bare revolving copper bars.

4th. No transformers to be used at the dynamo, but 10,000 volts to be obtained direct from the dynamo.

5th. A period of 8⅓ per second.

These specifications were accompanied by a design embodying them in a concrete form and showing that the copper bars were parallel to the axis.

With the exception of the first recommendation to use the two-phase system, I condemned the whole scheme, and said that a dynamo built after Prof. Forbes's drawing would not last a month, if it did a week.

The tremendous racking stress on each coil at the low period of 8⅓, the coil being of copper bars parallel to the axis without iron around it, all at a potential of 10,000 volts, was certainly sufficient to make me use very plain language. Again, the light revolving parts would cause such unsteady motion that I recommended them to be of larger diameter and weighing not less than 25 tons.

The system at Niagara to-day does not contain a single feature that I condemned. The whole of what Prof. Forbes intended as his final report has been swept away. One feature alone remains, the use of the two-phase system, and to this I agreed.

The system that I recommended is practically that in use at Niagara to-day in spite of Prof. Forbes's opposition to the very last.

The revolving parts are heavy, the armature contains iron, transformers to obtain the highest potential are to be used and a period of 25 per second has been adopted. The exact figures, however, have been somewhat altered. My "not less than 25 tons" for the revolving parts have become 40 tons, and my period of 42 or 33 has gone down to 25, and my revolving armature has become revolving magnets. As to whether the changes are for the better only time can show. As to whether 40 tons can be successfully revolved at 250 turns per second, a short time will decide. As to the charge of Prof. Forbes that I won my suit for the reason that the company had ordered my services though they did not act on my advice, the above is sufficient answer. I am perfectly satisfied with the extent to which the company profited by my advice.

But I have one word more to say, and that is with regard to the reason of my bringing suit against the company for so paltry a thing as a bill. Everybody who knows me at all knows that money forms a very small portion among the objects that I seek. But when men wish me to take my mind from those objects which I love, and devote it to their private money-making pursuits, I am then entitled to be compensated at the same rate as a first-class lawyer or physician. Furthermore, I have no right to degrade the profession of a man of science by undervaluing my services. Let everybody recognize that the successful pursuit of science requires quite as much brains and knowledge as that of law, and that a scientific error often equals in disastrous consequences a legal error.

Henry A. Rowland.

Johns Hopkins University, Baltimore, June 17, 1895.

PROF. DOLBEAR AS A TELEPHONE HISTORIAN.

Fig. 6.

When such well-known a scientific man as Professor Dolbear undertakes to pass judgment on the claims of rival inventors it is generally presumed that he is cautious enough to first post himself fully on the evidence of the cases he is dealing with. But, as not unusual, bias and personal grievances are the arbiters which guide the mind of some critics who undertake to pose as the historians of science. Professor Dolbear's heart beats for the down-trodden ones among the inventors. Bourseul is nowhere, Bell is nowhere, Edison and Berliner ditto. It is Reis and Hughes, the others are imitators and are to be classed with the rank and file of the hundreds who merely make improvements and receive patents therefor.

To open up the Reis-Bell controversy would lead to no results; the adage of "convincing one against his will" holds good in this case. But since it first filled the electrical press a new generation of electrical men have sprung up, and a short rehearsal of facts might be in place. Here is the inside history of Reis's pretensions.

In 1854 when Reis lived in Frankfort and was an active member of the Physical Society of that city, a prominent Frankfort paper called "Didaskalia" under the heading "Electrical Telephony" printed a leading article giving a full account of Bourseul's ingeniously conceived break and make transmitter and magneto receiver. And five years later Mr. Reis made such an apparatus as Bourseul had described, got musical tones, together with what at rare intervals appeared like a semblance to human speech—in spite of the intended breaks—and in his autobiography Reis modestly remarked: "*I called this instrument Telephone.*" The coincidence of the name thus coined by Reis with the heading "Electrical Telephony" of five years before is most remarkable, and the resemblance between the Reis apparatus and Bourseul's description still more so. But this should not be surprising because another claimant for the Speaking Telephone, named Daniel Drawbaugh, once swore that he invented a complete Blake transmitter, box, coil, springs, castings and all, in 1876, before Bell's magneto telephone was fairly completed. Why then not make it Reis, Drawbaugh and Hughes?

Well, for those performances of Mr. Reis he received that justly celebrated monument with the inscription "The Inventor of the Telephone," and to further flatter German national vanity his widow received a pension from the German government. On

the other hand Bell was refused a patent by the German Patent Office under the pretense because a few days before he applied for it, he had published his ideas in print.

But now a new allegation is made by Prof. Dolbear. Hughes, he says, was the first to use a piece of hard carbon for a contact transmitter.

If Prof. Dolbear had tried to search for facts he would have found that Mr. Berliner on Sept. 10, 1877, filed an amended drawing showing as Figure 6 the combination of a plate of hard carbon on a vibratory electrode in loose contact with a vibratory metal electrode, an embryo Blake transmitter contact.

Now Edison must have antedated Berliner because in the interference on the carbon contact Edison carried his record several weeks back of Berliner's record and received the patent.

Six months later then Sept. 10, '77, came Hughes, and made much noise and great pretensions. He coined the word "microphone," forgetting the iron principle that sound, being the sum of time and force, you cannot change its loudness except at the expense of quality. He mistook the incidental admixture of foreign sounds with the one to be transmitted, for an increase of the latter and without considering that he merely brought the sound closer to the ear drum. For that he is lauded by Prof. Dolbear and others as the inventor of the loose contact carbon transmitter.

Is there anywhere greater and more persistent injustice?

From the testimony in the Berliner Case it also appears that Berliner in Sept. 1877 spread broadcast a printed memorandum in which a loose carbon contact was described.

All this is on public record, right in the Boston Courts, near Prof. Dolbear's home, and the headquarters of the Bell Telephone Company, and it is inconceivable how a man of Prof. Dolbear's position can undertake to write History with so little regard to facts and fairness.

At one time Prof. Silvanus P. Thompson wrote in a similar strain to that of Prof. Dolbear and published a book "Reis the Inventor of the Telephone." But then Thompson had been retained by a rival telephone concern and for that reason allowance was made for his excursions into the land of sophistry. But what excuse has Prof. Dolbear for this fresh tirade against the merits of Bell and his co-laborers?

WERNER SUESS.

WASHINGTON, D. C., June 22, 1895.

TWELFTH GENERAL MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, NIAGARA FALLS, JUNE 26-30.

TUESDAY SESSIONS.

The twelfth general meeting of the Institute was called to order in the parlors of the Cataract House by the secretary Mr. R. W. Pope, who in the enforced absence of the retiring president, Prof. E. J. Houston, introduced the newly elected president, Dr. Louis Duncan, who took the chair amid applause.

THE PRESIDENT introduced the Mayor of Buffalo who welcomed the members of the Institute in a short address, and the reading and discussion of papers was then proceeded with.

The first paper read was that by Mr. W. E. HARRINGTON, on "Properties of Fuse Metals when Subjected to Short Circuits,"[1] which was followed by a lively discussion.

DR. L. WALDO thought that great caution ought to be observed in the use of aluminum fuses, as a slight admixture not exceeding 2 per cent. of iron or silicon raised its resistance to three times that of the pure metal. Frequently, also, copper and nickel were added to aluminum to make it draw better. MR. C. P. STEINMETZ thought that the constants obtained by Mr. Harrington held good only for the length of fuses employed in the tests, but did not apply generally to other fuse lengths. He did not think copper a suitable metal for fuses, owing to its high fusing point, except in special cases such as in electric car work. MR. C. J. REED believed that a fuse metal ought to have a low resistance instead of a high one, because its mass would then be less, and it would throw around less metal. PROF. W. A. ANTHONY criticized the paper on the ground that the author had assumed the resistance of the connections as negligible, which he deemed not to be the case, so that other results might have been attained with less resistance as a whole. PROF. ELIHU THOMSON believed that much depended on what the fuse was intended to do; if it was intended to protect merely for an overload, a lead tin fuse would be best. If intended to guard against a short circuit, copper would be best. MR. BLODGETT expressed the opinion that no formula with a single constant could express the law, as it depended upon the length of fuse and the duration of time. DR. A. V. GARRATT did not agree with the sweeping assertion of Mr. Harrington that fuse metals are to be depended on under no circumstances, but thought that they did protect under some. CAPT. WM. BROPHY was in general accord with the author's experience, but would modify Mr. Harrington's assertion to the extent that fuses are not to be depended on "under *most* circumstances." In his 12 years' experience he had tested common fuses and none of them had come anywhere near what they were advertised at. The discussion was also taken part in by PROF. F. B. CROCKER and others on similar lines.

1. See page 7 this issue.

This was followed by the reading by MR. C. P. STEINMETZ of his paper on "Theory of the General Alternating Current Transformer," which was discussed by DR. M. I. PUPIN. Mr. Steinmetz also referred to the fact that in his laboratory at Schenectady he had a machine, a sort of maid-of-all-work, which could be variously connected as an induction motor, a transformer, a two or three phase generator, or for converting from two to three phase, etc. PROF. DAVIS also took part in the discussion.

MR. C. E. GIFFORD, then read his paper on the "Location of Grounds in Armatures, Fields, etc." The meeting then adjourned until evening.

In the afternoon the members took carriages and were driven to the power house of the NIAGARA FALLS POWER CO., where they were afforded every opportunity for inspecting the apparatus there installed, which was fully described and illustrated in THE ELECTRICAL ENGINEER of June 26. One of the large 5,000 H. P. quarter phase generators was run with an artificial load of over 3,000 H. P. which was varied in order to demonstrate the sensitiveness of the regulator controlling the gates of the turbine. The switchboard gallery has just been equipped with the new "Niagara" type Shallenberger voltmeter, ammeter, and watt-indicator, described in THE ELECTRICAL ENGINEER of Jan. 2, 1895. There was also to be seen, though not erected in position, the table for controlling the main and field switches of the 5,000 H. P. generators. These will be operated by compressed air controlled by handles on the gallery table. Most of the members also descended to the bottom of the turbine shaft in the Otis electric elevator. The substantial character of all the work was commented on by all present.

The works of the PITTSBURGH REDUCTION CO. was the next point visited, the power room being alone opened to the visitors. This room was described and illustrated in our last issue.

THE CARBORUNDUM CO.'S WORKS, close beside those of the Pittsburgh Reduction Co., presented little of interest as the machinery has not yet been installed.

The electric light station of the BUFFALO & NIAGARA FALLS LIGHT & POWER CO. was visited by the members, some of whom also inspected the mills of the Niagara Falls Paper Co., close by, which take 6,000 H. P. direct from turbines.

THE evening session was opened by Prof. W. A. Anthony. He introduced PRESIDENT DUNCAN, who read his inaugural address entitled "The Substitution of Electricity for Steam in Railway Practice."[1]

In the discussion which followed MR. STEINMETZ discussed the limits of availability of the continuous and alternating current railway motor. He believed that for city street railways the 500 volt continuous current motor would hold the field against all comers; but on long suburban and interurban roads the alternating current would displace the continuous, being operated, either through the medium of rotary transformers with continuous current motors on the cars, or with alternating motors fed from stationary transformers. Of course the continuous current motor was preferable, because it could be used anywhere, and it was true that the alternating motor required two trolley wires; but on the other hand with stationary transformers any voltage can be used. He also advocated an underground railway conduit system at 110 volts. Mr. Steinmetz also exhibited curves showing the results of tests on a 3-phase railway motor which showed a torque of 1,600 lbs. at ½ speed, 2,800 lbs. at full speed and a maximum torque of 8,000 lbs. acting on a 33-inch wheel, a torque, comparable to that of the largest steam locomotives. This machine was designed for 110 volts.

MR. OBERLIN SMITH believed that contrary to Dr. Duncan's view railways electrically equipped could handle freight as well as passengers. DR. DUNCAN in reply stated that there was no question as to the possibility of electric roads handling freight as well as passengers, but that steam roads were not in condition to undertake such electric traction at the present time. He believed that to meet the competition of parallel electric roads they would either have to build two additional tracks electrically equipped or buy out the competing electric roads.

PROF. ELIHU THOMSON then read his paper on "Compounding Dynamos by Armature Reaction."

SECRETARY POPE announced that the Long Distance Telephone Co. had placed all its lines throughout the United States at the disposal of the Institute members.

WEDNESDAY SESSIONS.

The day's meeting was opened by the reading of the paper on "Electric Power in Factories," by Prof. F. B. Crocker and Messrs. Benedict and Ormsbee. Prof. Crocker also exhibited curves illustrating the amount of power used in a certain factory operating shafting by belting. At noon time the shafting alone was run, when it was shown that the latter absorbed three-fourths of the total power of the engine. DR. C. E. EMERY showed, how, by

1. See page 8 this issue.

electric driving any department in a factory could be run overtime without loss. He did not believe that any hard and fast rule could be laid down as to whether each machine should be equipped with its individual motor, or each set of machines with a section of shafting electrically driven. MR. H. WARD LEONARD related his experience in driving a cloth printing roll, which had been successfully accomplished, and resulted in the displacement of a steam engine used for the purpose. MR. G. S. DUNN believed that the great loss of 80 per cent., found in shops driven by shafting was due to the fact that the tools are in use only a fraction of the whole time. He did not consider 75 per cent too high a loss, and had known of a case as high as 85 per cent. In the new shops of the Crocker-Wheeler Electric Co., the conductors will be run under the floor and brought up at each machine. The discussion was also participated in by MESSRS. WHEELER, BLODGETT, ALEXANDER and BROPHY.

MR. C. P. STEINMETZ then read his paper on "Some Features of Alternating Current Systems," which elicited no discussion.

SECRETARY POPE announced that the resolutions adopted by the Institute in memory of the late treasurer, MR. GEORGE M. PHELPS, had been engrossed, and they were placed on view in the hall.

The paper of PROF. D. C. JACKSON and MR. S. B. FORTENBAUGH on "Some Observations on a Direct-Connected 800 Kilowatt Monocyclic Alternator,"[1] was then read by MR. FORTENBAUGH, and briefly discussed by MESSRS. DUNN and STEINMETZ.

In the afternoon the members took a special train placed at their disposal by the Niagara Falls Park and River Railway and made the trip to Queenston and Chippewa, stopping at the Whirlpool Rapids, the Power House and other points of interest along this excellently equipped electric railway.

The evening session was taken up with the paper of DR. C. E. EMERY on "The Cost of Steam Power—II." In the discussion which followed PROF. ANTHONY pointed out that the Niagara Falls Power Co. proposed to base their charge on the maximum power used as determined by meter, and hence it would be unfair to a consumer since the average power used is usually far less than the maximum. PROF. CROCKER believed that the low cost of power which one frequently hears of is due to the fact that power users figure by taking the total cost and then dividing by the maximum power of the plant, instead of dividing by the average power developed. DR. EMERY stated that the Niagara Company proposed to sell undeveloped power at $10, power at turbine shafts for $18, and electric power at dynamo terminals for $18 per H. P. per year. Mr. L. B. STILLWELL thought that in order to make a fair comparison the cost of electric generators, etc., should have been added to DR. EMERY's estimates. MR. B. J. ARNOLD pointed out the fact that in well designed electric central stations energy was now delivered at the switch board for 1 cent per H. P. hour. The discussion was also taken part in by MESSRS. SMITH, PERRY and GARRATT.

THURSDAY SESSION.

The morning session was opened by DR. EMERY, who supplemented his paper read the evening before by instancing a case which had came under his observation, in which electricity did not figure out as the most economical means of transmission, owing to the fact that the heat of the exhaust steam was utilized and constituted the larger portion of the work.

DR. A. M. BLEILE, then read his paper "On the Cause of Death in Electric Shock,"[2] which elicited quite a lively discussion. Referring to the observed fact that little or no bleeding was seen after incision into the animal's body after death from a low frequency current, PROF. ELIHU THOMSON suggested that high frequency currents might be used for the resuscitation of persons shocked by electricity since experience had shown that a wound made immediately after the application of a high frequency current bled very freely. In reply to a question by PROF. ANTHONY, Prof. Thomson said that experiments made by him seemed to prove that high frequency currents did actually pass through the body and not merely along the surface as was generally supposed. MESSRS. BLODGETT, NEHER and GARRATT also participated in the discussion.

MR. G. H. WINSLOW was then introduced and read his paper on "Long Distance Power Transmission at 10,000 volts (the Pomona, Cal., Plant), describing a transmission over 28¾ miles.

DR. C. E. EMERY read his paper on "Alternating Current Curves," after which the members adjourned to the hotel porch and were photographed in a group.

The afternoon was spent by the members in visits to the Observation Tower, which affords a magnificent bird's-eye-view of the Falls and surrounding country; to the Buttery Elevator at the Whirlpool Rapids, and other places of interest which had been thrown open to them for the occasion.

The evening session was opened by the reading, in abstract, of MR. F. L. POPE'S paper on "Notes on the Reconstruction of a Small Station Plant." DR. EMERY thought the paper worthy of special attention as a typical engineering paper, in that it showed the steps followed and the reasons therefore.

1. See page 4 this issue. 2. See page 6 this issue.

The President then introduced DR. COLEMAN SELLERS, who gave a most interesting account of the mechanical and civil engineering features of the great Niagara water power project, and pointed out the reasons which had dictated the designs adopted. He concluded by remarking that thus far all the expectations of the projectors and designers had been fulfilled, and that if any mistakes had been made they related only to very minor points. Dr. Sellers' address was illustrated by views and diagrams thrown on the screen by a lantern.

He was followed by MR. L. B. STILLWELL, electrical engineer of the Westinghouse Co., who also, by means of the lantern, described the electrical features of the Niagara plant.

FRIDAY SESSION.

THE closing session of the meeting was opened by a discussion of Dr. Emery's paper on "Alternating Current Curves" which was participated in by PROF. PUPIN and MR. STEINMETZ.

MR. W. L. R. EMMET then read his paper on "Existing Commercial Applications of Electric Power from Niagara Falls," in which he described the apparatus furnished by the General Electric Co. to the Niagara plant. The paper brought out a very lively discussion.

MR. B. G. LAMME criticised the general construction of the machines installed in the works of the Pittsburgh Reduction Co. and compared the rotary transformers there employed with similar ones used in the Niagara power house for exciting the 5,000 H. P. generators. He also criticised the use of copper brushes on the rotary transformers of the Pittsburgh Co. and believed that carbon brushes ought to have been employed. In reply, MR. EMMET stated that the machines were designed to conform to fixed specifications furnished by the Cataract Construction Co., and that these were adhered to to the letter.

After adjournment a number of the Institute members attended an exhibition of the BURTON ELECTRIC FORGING PROCESS in which the metal is heated under water. Mr. J. O. Adsit of the Burton Electric Forging Co., explained the process.

The names of those in attendance are:—

A. V. Abbott, A. Ackermann, Jos. S. Alden, Harry Alexander, H. S. Anderson, Geo. F. Archer, B. J. Arnold, Prof. W. A. Anthony, H. D. Bayne, W. D. Bayne, Eskie Berg, E. J. Berg, G. H. Blaxter, A. M. Bleile, Geo. W. Blodgett, W. J. A. Boucher, Frank Bourne, T. D. Boyles, W. A. Brackenridge, Chas. S. Bradley, E. Carl Breithaupt, Frank Brewer, William Brophy, James Burke, C. C. Burr, F. C. Busch, F. C. Caldwell, Henry S. Carhart, A. D. Chandler, Prof. C. F. Chandler, Edward A. Colby, E. P. Coleman, Stephen L. Coles, Geo. W. Colles, Jr., C. C. Collins, C. L. Cornell, J. B. Cornell, Jr., Maurice Coster, H. A. Cragin, Dr. F. B. Crocker, Jos. F. Cummings, G. W. Davenport, Prof. J. E. Davies, H. M. Davis, D. de Lancey, Fred. De Land, A. A. Dion, Bert W. Douglas, J. D. E. Duncan, Dr. Louis Duncan, Th. C. Dunlap, W. K. Dunlap, Gano S. Dunn, William C. L. Eglin, William Elmer, Jr., Alfred Ely, Dr. Chas. E. Emery, W. L. R. Emmet, Thos. H. Feary, R. A. Fessenden, H. W. Fisher, H. Foltz, M. Foltz, A. Fortenbaugh, S. B. Fortenbaugh, Horatio A. Foster, W. G. Fuller, A. V. Garratt, C. E. Gifford, S. R. Gifford, J. W. Gilmore, D. L. Goff, S. D. Greene, J. L. Hall, W. J. Hammer, W. J. Hamilton. Jr., Walter E. Harrington, Harold Hakenson, J. R. Haskin, E. H. Heinrichs, Carl Hering, Charles E. Hewitt, Charles K. Hugnet, Charles B. Hunt, F. S. Hunting, L. E. Imlay, J. Jordan, John L. Kepler, W. W. Ker, B. S. Lamphear, H. Ward Leonard, William B. Lester, P. M. Lincoln, Herbert Lloyd, R. McA. Lloyd, Dr. Walter Lobach, Jos. Lyman, D. N. McBrier, R. D. McCarter, Ralph McNeill, Prof. A. Macfarlane, Robt. B. Mann, E. B. Merrill, Percival R. Moses, Jules Neher, W. W. Nicholson, Alexander F. Ormsbee, Max Osterberg, Prof. R. B. Owens, Charles P. Peret, L. Knowles Peret, Frank C. Perkins, Nelson W. Perry, Walter M. Petty, R. Pfund, F. M. Pike, Charles Plumb, C. P. Poole, Franklin L. Pope, Ralph W. Pope, H. Hobart Porter, Jr., Dr. M. I. Pupin, George A. Redman, C. J. Reed, Harry D. Reed, H. G. Reist, E. W. Rice, Jr., J. W. Rogers, T. R. Rosebutgh, M. R. Rothschild, Wm. M. Rutherford, C. W. Ryan, E. N. Sanderson, Charles F. Scott, A. B. See, Coleman Sellers, H. B. Shallenberger, O. B. Shallenberger, John C. Shedd, Oberlin Smith, Charles P. Steinmetz, L. B. Stillwell, Henry T. Stott, H. B. Sweet, E. V. Swenson, H. W. Swetland, W. S. Symington, F. Taft, Prof. B. F. Thomas, Elihu Thomson, C. Thordarson, J. W. Tillinghast, Chas. A. Tinker, F. Torchio, C. R. Van Trump, Horace S. L. Verley, John Waring, Leonard Waldo, A. B. Weaver, W. D. Weaver, Edwin R. Weeks, Joseph Wetzler, Dr. S. S. Wheeler, J. C. White, E. F. Williams, George H. Winkler, Jr., G. H. Winslow, George P. Wisdom, G. C. Wolverton, Peter Wright, Alex. Jay Wurts, T. H. Yawger, Charles I. Young.

The ladies present were:—

Miss Alexander, Mrs. E. Bayne, Mrs. H. D. Bayne, Mrs. C. L. Cornell, Mrs. J. E. Davies, Mrs. H. A. Foster, Miss G. Fraser, Miss E. Fraser, Mrs. C. E. Gifford, Miss E. Gumming, Mrs. Chas. B. Hunt, Mrs. W. W. Ker, Mrs. Herbert Lloyd, Miss Maud Noble, Miss D. Osterberg, Mrs. Nelson W. Perry, Miss Perry, Miss Plumb, Mrs. M. I. Pupin, Mrs. George A. Redman, Mrs. F. Torchio, Miss Ruth Weeks, Mrs. H. R. Wemple.

THE FISKE POSITION FINDER.

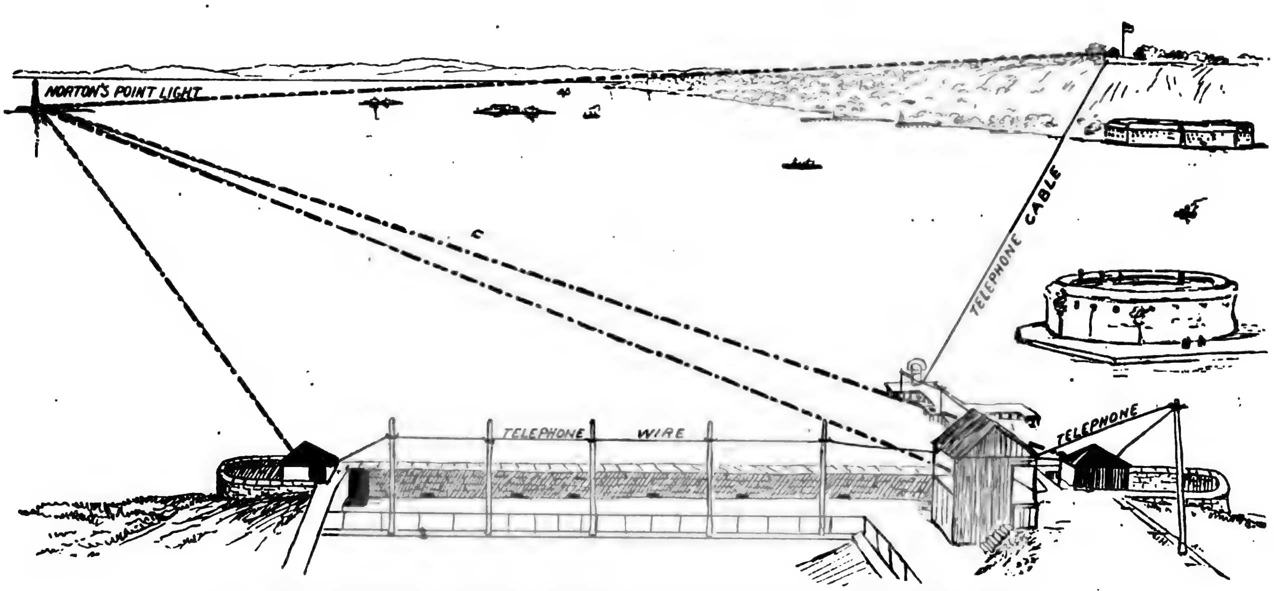
In our issue of April 12, we described Lieut. Fiske's range finder as it is now used in the U. S. Navy. On June 25th there was an official test at Fort Hamilton, New York Harbor, of Lieut. Fiske's new position finder, which differs from the range finder in this respect: the range finder is simply an instrument which finds the distance of the target from itself; while the position finder locates upon a chart the position of the target; that is, its distance and direction from some given point. Usually, but not

THE FISKE POSITION FINDER.

necessarily, this given point is one of the instruments of the position finder. The test undertaken at Fort Hamilton by the Board appointed by the Ordinance Department was for making estimates by the position finder of the range and direction of various objects, and comparing them with a known standard. The standard adopted for the purposes of comparison was furnished by a set of triangulating instruments, one of which was at Fort Wadsworth on the Staten Island side of the Narrows, and the other at Fort Hamilton, the operators being connected by telephone. At each place there was a telescope mounted upon a heavy brass pedestal, which was divided accurately into degrees and minutes, and used to show the angle at which each telescope was directed. These two stations were about 2,100 yards apart. of the tests will not be known for some little time to come, but from the favorable impression produced at the test by the operation of the position finder there seems little doubt of its approval by the Board.

This instrument, besides finding the position at the moment, also predicts what the position will be a short time afterwards. The position of the object is plotted on the chart for 30 seconds, and these positions are joined by a line more or less broken. This line shows, of course, the track of the vessel or other moving body so that the prolongation of the line gives the direction in which it will move in, say, the next 30 seconds. By laying off on this prolongation of the line the distance equal to that which the ship traverses in the previous 30 seconds, the point is given where she will be at the end of the next 30 seconds. In military parlance, this process is termed "predicting the position." The position finder, then, may be said to be an elaboration of the range finder.

Range finders have been used some time for artillery and infantry purposes; at least their use has been attempted with partial success, especially in England, where a great deal of attention has been paid to the subject. Many forms of the range finder have also been tried on board ships but with indifferent success, until the appearance of the Fiske range finder, which is the only one that has made naval range finding really possible. Both range finders and position finders have been used with good results in forts in Europe, and more particularly in England, where many of the forts are upon high ground. The instruments have been for the most part based upon the solving of a right-angled triangle of which one side is the height of the instrument above the water, and the known angle is the depression of the telescope placed on the instrument and depressed below the horizontal at the water line of the vessel under observation. These instruments are used in a variety of forms all over Europe, and they work with considerable accuracy where the height is sufficiently great to form a good base. Their great enemy is the changes in the refraction of the atmosphere, which alter the direction of a ray of light coming from the object on the water to the telescope. Another difficulty in their operation is the smoke produced by the firing of the gun, which frequently hides the hull of the ship from the operator and covers the surrounding water with an impenetrable cloud. Where the land is so low that a sufficient eminence cannot be got for mounting an instrument of this character, recourse must be had to triangulation, using a horizontal base. Of course it would be bad from a military point of view to raise any conspicuous structure wherein to place the instrument. Siemens & Halske some years ago got out an instrument of this character in which tele-



TESTING THE FISKE POSITION FINDER AT FORT HAMILTON, NEW YORK HARBOR.

An elaborate system of sighting was adopted which enabled the telescopes at the different stations to be directed simultaneously at any desired point. Near the telescope was a chart carefully marked out in angles and distances. In making an observation upon a stationary point, such as the Coney Island Lighthouse, it was merely necessary to place two pointers, which were pivoted over the chart at the angles of the two telescopes. In the case of moving objects, such as steamers going up and down the Harbor, a signal would be arranged by telephone at which the observers at each end would sight the vessel at the same instant. The results obtained would be eventually worked out and plotted, and compared with those given by the position finder. The result scopes were placed at the ends of a base line of known length, and were connected together by electro-mechanical means, so that the movements of the telescopes in horizontal angles operated pointers, which indicated the distance and the direction. Another class of extremely complex position finders have been tried in Europe unsuccessfully. The complexity of the instruments was fatal. The slipping of a pawl, or the jumping of a ratchet, caused errors which were cumulative, as it was found impracticable to keep putting the apparatus at unison, as is done with the printing telegraph. By the adoption of the principle which Lieut. Fiske has worked out in his range finder, all difficulties of this nature were overcome, as there are no springs, or pawls, or

ratchet or making and breaking of contacts, because the indicator is a galvanometer whose indications depend simply upon the increase and decrease of current due to the movements of hard contacts over unbroken wires of high resistance.

A position finder of much merit, invented by Lieut. I. N. Lewis, and designed to operate with vertical base line was also placed in the hut seen to the left of the diagram showing the scene of the tests at Fort Hamilton. Readings were taken throughout the day with this instrument, which is based entirely on mechanical principles. It may be mentioned that one of the advantages of the Fiske position finder is that it can be used with a vertical as well as with a horizontal base, and in such case a 50-foot base would be sufficient for its operation. We are indebted to the New York *Sun*, for the cuts from its own admirable article on the test.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JUNE 25, 1895.

Alarms and Signals:—

Code Signaling Device, W. Rymer, Detroit, Mich., 541,505. Filed July 2, 1894.

Designed for use in connection with a steam or similar whistle, the signals being controlled by electricity, to give the signals required by any given code, automatically.

Burglar Alarm, C. M. Clark, New York, 541,719. Filed Apl. 12, 1895.

Consists of an electric circuit, containing a magnetic coil to influence the electric current, by a person moving toward or from the coil, a galvanometer arranged in the circuit, and an alarm controlled by the galvanometer.

Conductors, Conduits and Insulators:—

Combined Insulator and Fuse Holder, C. F. Scott and H. P. Davis, Pittsburg, Pa., 541,459. Filed July 16, 1894.

A form of combined insulator and safety plug or fuse holder available for outdoor use.

Protector Casing for Underground Electric Conductors, J. A. Kingdon, London, Eng., 541,552. Filed Aug. 9, 1894.

Protects the conductor by an inverted U-shaped metal trough closed at the bottom and having sleeves at the abutting sections.

Distribution:—

Transmission of Power by Alternating Currents, F. S. Hunting, Fort Wayne, Ind., 541,615. Filed Jan. 19, 1895.

Provides a means for generating di-phased currents at the point to which the power is electrically transmitted, whereas only simple or mono-phased currents are produced at the point where the energy is generated.

Dynamos and Motors:—

Electric Elevator Apparatus, F. B. Perkins, Boston, Mass., 541,497. Filed Dec. 15, 1893.

The combination with the motor, rheostat and switch controlling the circuits of the motor, of a brake magnet included in the circuit, the arrangement being such that as the circuit is closed to start the motor a greater portion of the current shall flow through the brake magnet to operate the same.

Electrical Controller for Motors, O. H. & A. F. Pieper, San Jose, Cal., 541,500. Filed Apl. 30, 1894.

Means for controlling electric dental, surgical or other electrical apparatus of the kind.

Electric Brake Controller, F. E. Herdman, Winnetka, Ill., 541,545. Filed Dec. 18, 1894.

When the current passing through the armature of the motor for any other reason becomes excessive, the electric circuit to the armature is automatically opened and the brake automatically applied.

Alternating Current Motor, R. Eickemeyer, Yonkers, N. Y., 541,604. Filed Sept. 28, 1891.

Relates to a system of winding for single phase currents intended especially for light service work, such as electric meters and other measuring instruments.

Electric Motor, W. J. Still, Toronto, Canada, 541,641. Filed Aug. 9, 1894.

Details of construction to reduce hysteresis in the armature.

Device for Removing Resistances in Starting Electric Elevators, G. H. Whittingham, Baltimore, Md., 541,798. Filed May 24, 1894.

The gear of the elevator mechanism furnishes the power for operating the resistance controlling device.

Electrometallurgy:—

Electrolytical Process and Apparatus, C. T. J. Vautin, London, Eng. 541,465. Filed June 26, 1894.

Relates to the electrolytic production of an alloy of lead and tin with the alkaline metals.

Lamps and Appurtenances:—

Electric Arc Lamp, A. W. Smith, Washington, D. C., 541,460. Filed April 25, 1895.

In an arc lamp, a flexible feed ribbon, engaging with a retarding device on the movable carbon support, and means for imparting an up and down movement to the ribbon, and also means for varying the tension on the ribbon.

Repairing Incandescent Lamps, J. Möhrle, Munich, Germany, 541,421. Filed Jan. 25, 1895.

A process for inserting and securing the new filament in place.

Carbon Electrode for Electric Arc Lamps, S. Heimann, New York, 541,541. Filed Oct. 5, 1894.

A carbon electrode for electric arc lamps, in which are incorporated, infusorial earth, chloride of zinc, chloride of ammonia and yellow prussiate of potash.

Electric Arc Light, E. A. Edwards, Cincinnati, Ohio, 541,603. Filed Sept. 19, 1894.

Details referring to a locomotive head light.

Miscellaneous:—

Electromagnet, F. B. Corey, Boston, Mass., 541,471. Filed Apl. 15, 1895.

Relates to electro magnets designed for actuating apparatus in which a mechanical movement is effected by electrical means, and especially to such apparatus as requires that this movement shall be made slowly.

Automatic Electric Gas Lighter, W. N. Jaskey and E. S. Eise, Logan, Utah, 541,549. Filed Aug. 20, 1894.

Claim:—In an automatic electrical gas lighter the combination of a burner a fan support extending above the burner, a fan pivoted to the support and electrical contacts also mounted on the fan support arranged to be actuated by the movement of the fan.

Method of and Apparatus for Manufacturing Sulphuric Acid and By-Products, J. D. Darling, Philadelphia, Pa., 541,597. Filed Jan 8, 1895.

Consists in electrolytically decomposing a fused nitrate, directly conducting the disengaged gases, without further conversion, to the Glover tower, and recovering the basic residuum of the electrolytic action.

Process for Utilising Nitre Cake or Other Acid Sulphates, J. D. Darling, Philadelphia, Pa., 541,598. Filed Jan. 8, 1895.

Consists in electrically decomposing an electrolyte containing a similar base to that of the sulphate, and transferring said base to the sulphate by electrolytic travel.

Electric Gas Lighter, J. L. Creveling, New York, 541,723. Filed June 21, 1895.

Specially applicable to the "Pintsch" gas system.

Thermo Controlled Electric Heater, L. E. Custer, Dayton, Ohio, 541,724. Filed Dec. 22, 1894.

Especially designed for dental uses in the making of artificial teeth and plates.

Railways and Appliances:

Method of Preventing Electrolysis of Pipes Underground, H. P. Brown, New York, 541,467. Filed Dec. 10, 1894.

Claim:—The system or method of preventing electrolytic decomposition of underground pipes, consisting in maintaining said pipes in a negative condition in respect to the rails by connecting to the point on said pipes where there would otherwise be a positive potential, a feeder wire or conductor leading to the negative pole of a dynamo or other source of electrical energy, said pole having a greater negative potential than the rails.

Conduit Electrical Railway, E. Ebi, Cedar Rapids, Iowa, 541,730. Filed July 5, 1894.

Means of lowering or raising both wheels to throw them in and out of contact with the wires.

Trolley Finder, J. P. Taylor, Fort Worth, Texas, 541,796. Filed Mch. 12, 1895.

Switches, Cut-Outs, etc.:—

Fuse Block, H. P. Davis and C. F. Scott, Pittsburg, Pa., 541,473. Filed Oct. 23, 1893.

The vapors produced by the destruction of the fuse are disposed of in such a manner as to preclude any injury to the terminals between which the fuse is interposed.

Automatic Working Rheostat for Starting Electric Motors, F. E. Herdman, Winnetka, Ill., 541,543. Filed Nov. 24, 1894.

Automatic Working Rheostat for Starting Electric Motors, F. E. Herdman, Winnetka, Ill., 541,543. Filed Nov. 24, 1894.

Electric Motor, F. E. Herdman, Winnetka, Ill., 541,544. Filed Nov. 27, 1894.

Relates to a starting mechanism.

Electric Switch, W. P. Hancock, Everett, Mass., 541,608. Filed Feb. 7, 1895.

Relates to a double throw knife snap switch.

FINANCIAL.

STOCKS LOWER AND DULL.

The past week witnessed a dullness in electrical and other stocks that at last culminated in a decline, owing to the lack or support given. As a matter of fact, it cannot be said that the general market exhibited any decline in strength, but the symptoms were rather those of lassitude and reaction. An illness of two years is not to be rallied from in one summer month. During the week 38,600 General Electric shares were dealt in down to 35⅜ showing a net decline of ⅛, but quotations at one time went as high as 37½. The decline was even greater in Western Union which went off 1, and down to 91 on sales of 10,809 shares. American Bell Telephone was off to 195½ on Saturday. The stockholders of the latter company have voted to issue another $1,000,000 of stock, making the total capitalization $21,500,000 for the parent company alone.

OBITUARY.

ALTON J. SHAW.

The death is announced at Muskegon, Mich., of Mr. A. J. Shaw, president of the Shaw Electric Crane Co., at the early age of 37. He was educated at Auburn, Me., and graduated from Bates College. He went into the employ of the E. P. Allis Co., of Milwaukee, and there invented the well-known electric crane bearing his name, to which he had devoted his energies for some years past. He had great inventive ability with marked mechanical aptitude. He leaves a widow and a daughter. His illness, due to peritonitis, lasted only four days.

HENRY W. FRYE.

We regret to note the death at an early age of Mr. H. W. Frye, formerly associate editor of *The Electrical World*. He resigned his position some time ago utterly broken in health and went to New Mexico to recuperate, but consumption wrought its work swiftly. Mr. Frye was a most amiable and talented young man, and the profession to which he sacrificed his life is the loser by his untimely death.

J. S. O'Brien.—J. S. O'Brien, late superintendent of the Telephone and Electric Light Companies in Scranton, died at his residence in that city recently, aged 52 years. He began his career as telegraph operator for the Pennsylvania R. R. at Greensburg, and served during the war in the United States military telegraph corps.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT

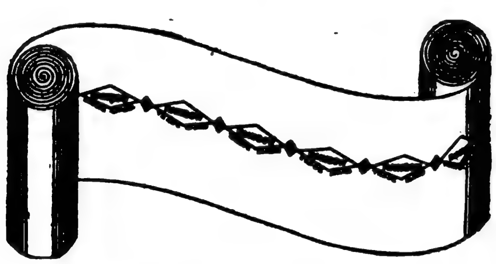
Mr. JUSTUS B. ENTZ,

Mr. Justus B. Entz, the electrical engineer, has opened an office for consultation purposes at room 135, Potter Building, N. Y. He is prepared to make examinations of and report upon new inventions and new enterprises, to issue specifications and supervise installations for light and power work. He is also ready to design and remodel dynamos and motors, and bring such apparatus up to the standard of modern practice. He will also make a specialty of designs and specifications for large accumulator plants with automatic switchboard controlling devices for same. Mr. Entz has had a ripe experience. He was chief electrician of the Edison Machine Works in 1889, and patented and designed, to Navy specifications, the first direct-connected multipolar dynamos in this country, for the cruisers "Philadelphia," "Baltimore," "San Francisco," "Charlestown," "Yorktown," etc. Later he was one of the incorporators of the Waddell-Entz Co., and the inventor and designer of the dynamos, motors and batteries of that company. For the past year he has been engineer with the Accumulatoren-Fabrik Aktien Gesellschaft, of Hagen, Germany, and has been studying storage battery work and their installation for central stations, isolated and train lighting. This brief record of Mr. Entz's busy career will give some idea of his ample qualifications for the work he is now undertaking.

RAINBOW PACKING OF THE PEERLESS RUBBER MFG. CO.

Among the many standard products of the Peerless Rubber Mfg. Co., 16 Warren street, New York, in the shape of mechanical rubber goods, none perhaps is better known than its celebrated "Rainbow" packing, of which an illustration is here given of a roll, in fac simile, bearing the familiar trademark. The well nigh incredible statement is made that over 4,000 tons of "Rainbow" have been sold in the last five years. It is made in rolls of about 200 pounds each, in sizes from 1/16 up to 1/2 inch.

This packing is especially adapted for very high pressure, and is not affected by any degree of steam heat. It will not harden under any degree of heat, or blow out under the highest pressure, and will make an air, steam, hot or cold water joint equally well.



ROLL OF "RAINBOW" PACKING.

It is not affected by oils, ammonia, liquors, steam, heat or alkalies. Unlike plumbago and usudurian, it will not harden or crack. Joints can be made and broken in one-eighth the time consumed with packings that harden, as a tool is not required to break or face off the joint.

In a letter of last April, D. W. Lanigan, the chief engineer of the enormous South Pump Water Works of Chicago, states that he has used "Rainbow" from the time it was first introduced, and upon joints exposed to steam at high pressure, and has found it exceptionally durable, reliable and economical. It is evident that such packing must be a notable element in the efficiency of electric light, railway and power plants, where it is always essential to get the utmost value out of the steam.

ORDERS FOR BALL ENGINES.

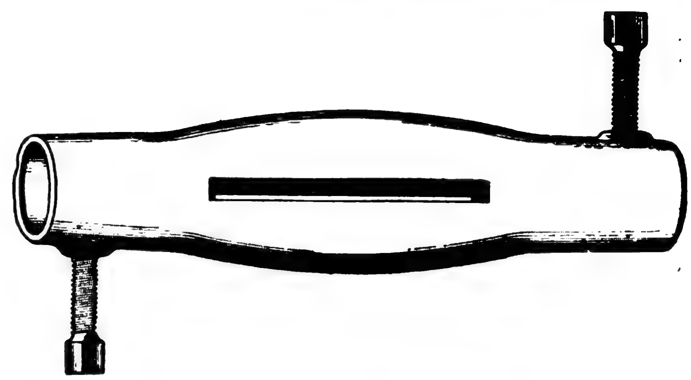
Crook, Horner & Co., Baltimore representatives of the Ball Engine Co., Erie, Pa., are installing three 175 H. P. Ball engines in the new Congressional Library Building, Washington. These engines are direct connected to Mather dynamos and the plant will be one of the most complete of its size in the country. The City of Galveston, Texas, is putting in an electric light plant in its municipal building. The engine is a "Ball" automatic and is direct connected to a Western Electric dynamo. An electric plant will be installed in the new Security Building, St. Louis. The Ball Engine Co. furnish the engines and the Western Electric Co. the dynamos.

ROEBLING'S "BALTIMORE" CONNECTOR FOR RAILWAY FEEDERS.

AN efficient connector for over head lines of heavy stranded weatherproof wire has been introduced recently by John A. Roebling's Sons Co. It is intended for use in joining concentric laid strands, and to replace the inefficient connectors heretofore employed for this purpose. Many of these are objectionable from their high first cost and the long time consumed in their application. These joints are unsightly when finished and suspended on a line and vitally defective in power to resist the strain due to stringing the strands.

The "Baltimore" connector is a hollow brass tube, thoroughly tinned, with a slot extending to within two inches of each end. The outside diameter at the centre of a connector for 500,000 C. M. is 1 5/8 inches, tapering to 1 1/4 inches at each end, with set screws in each end to hold the strand in place while solder is run in.

To apply the connector, the ends of the strand are stripped of insulation, the connector is slipped on, the ends of the strand brought together flush and the screws are set up tight. With an ordinary flat tool the wires in the strand are pressed out against the inner sides of the connector, and solder is then run into the joint. When covered with good friction tape the joint is barely perceivable at the elevation of an ordinary pole line.



THE BALTIMORE "CONNECTOR."

The Roebling Co. are also furnishing heavy feeder wire in extra long lengths. With wire in long lengths and the use of the Baltimore connectors, much time and labor is saved in the erection of a pole line.

WARREN WEBSTER & CO.'S RECENT ORDERS.

WARREN WEBSTER & Co., Camden, N. J., specialists in examining steam plants where increased economy in fuel is desired by utilizing waste exhaust steam, report considerable activity in their business. Among the recent orders for the Webster "Vacuum" feed water heater and purifier not reported since May, and in addition to numerous contracts for their vacuum system of steam heating, without back pressure upon the engine —Webster steam and oil separators—they mention:

Haldeman Paper Co. (2 heaters), Lockland, Ohio, 1,000 H. P.; Putnam Hooker & Co., Cincinnati, Ohio, 350 H. P.; Philadelphia Construction Co., Philadelphia, Pa., 500 H. P.; William Oswald, New Orleans, La., 75 H. P.; Dominion Oil Cloth Co., Canada, 150 H. P.; Harrisburg Fdy. & Mach. Co., Harrisburg, Pa., 300 H. P.; Temple Elec. Co., Temple, Texas, 150 H. P.; Buckner Orphans Home, Dallas, Texas, 100 H. P.; Philadelphia Construction Co., Philadelphia, Pa., 1,000 H. P.; Wilkesbarre & Wyoming Valley Traction Co., Wilkesbarre, Pa. (dupli.), 1,200 H. P.; Kittanning Elec. L., H. & P. Co., Kittanning, Pa., 250 H. P.; Morrison Plummer Co., Chicago, Ills., 200 H. P.; Diamond Match Co., Oshkosh, Wis., 500 H. P.; Enterprise Machine Co., Minneapolis, Minn., 50 H. P.; Chas. Roeser, Moundsville, W. Va., 150 H. P.; B. F. Gentsch & Sons, Buffalo, N. Y., 100 H. P.; Seltzer & Bro., Pottsville, Pa., 200 H. P.; H. Belfield & Co., Philadelphia, Pa., 200 H. P.; Deering Harvester Co., Chicago, 1,250 H. P.; Knox Hill Co., Warsaw, Ill., 100 H. P.; Mississippi Cotton Oil Co., Vadalia, La., 250 H. P.; Mississippi Cotton Oil Co., Jackson, Miss., 250 H. P.; Kaukauna Fibre Co., Kaukauna, Wis., 175 H. P.; Thilmany Paper Co., Kaukauna, Wis., 150 H. P.; Wire Goods Co., Worcester, Mass., 150 H. P.; Badger Paper Co., Kaukauna, Wis., 500 H. P.; J. J. Kenyon, Pawtucket, R. I., 300 H. P.; P. H. Potter, Springfield, Mass., 300 H. P.; Nonantum Worsted Co., Newton, Mass., 1,600 H. P.; Amory Mfg. Co., Manchester, N. H., 1,500 H. P.; Freeland Elec. L., H. & P. Co., Freeland, Pa., 320 H. P.; G. L. Brownell, Worcester, Mass., 100 H. P.; Boston Rubber Shoe Co., Malden, Mass., 600 H. P.; Jay Paper Co., Jay Bridge, Me., 500 H. P.; Henry Frey & Co., Boston, Mass., 250 H. P.; Uncas Paper Co., Norwich, Conn., 600 H. P.

MEDBERY WEATHERPROOF WALL SOCKET, FOR ILLUMINATED SIGNS.

The superiority of this socket, has been thoroughly demonstrated in its use for illuminated sign work, and it is popular for this purpose. There is no danger of fire from it, as all the connections are inside, and the composition is forced around them, under enormous pressure, making a socket of great strength and durability and one that is practically indestructible. Water cannot follow the wires and make a short circuit. The E. S. Greeley & Co., No. 5 and 7 Dey street, New York, are the New York agents, and keep a stock constantly on hand.

THE RUSSELL SWITCH.

The Electric Appliance Company, Chicago, are general selling agents for the Russell Automatic switch, having just closed exclusive arrangements. By means of this device a light or group of lights can be controlled independently from any number of points without any additional electric light wiring. The Russell switch is usually placed in the cutout box and a single circuit run to the light or group of lights to be controlled. From the switch, circuits of No. 18 wire are run to the points from which the lights are to be controlled where an ordinary gas key does the work. Pressing the white button, turns on the lights and pressing the black button, turns them off. The Russell devices are now approved by the National Board of Fire Underwriters and will undoubtedly meet a large sale.

TAKING 3,000 VOLTS.

FOREMAN F. E. Glover, of the Rochester, N. Y., Gas and Electric Co., was accidentally the recipient, some days ago, of a current of about 3,000 volts. It was about an hour before any signs of life could be detected by those who worked on him, using the d'Arsonval methods of resuscitation. Respiration began very slowly, but at last, although badly burned, he was revived and is now practically a well and sound man.

RECEIVER APPOINTED FOR THE SCHUYLER ELECTRIC CO

Ex-Congressman Lewis Sperry has been appointed receiver of the Schuyler Electric Manufacturing Company of Hartford, by Judge Thayer in the Superior Court. The Schuyler Electric Manufacturing Company sold its assets, including patents, to the Schuyler Electric Company of Middletown. The Supreme Court has decided that the sale was illegal, hence all the assets must be returned to the former company.

MR. A. L. REINMANN.

MR. A. L. REINMANN, well known to all old electricians, has accepted the position of Superintendent of the American Elecl. Manfg. Co., St. Louis; and his ability as a manufacturer of incandescent lamps will add to the already excellent quality of this Company's productions. Mr. Reinmann is well remembered as the former Superintendent of the Westinghouse lamp factory at Pittsburgh, and later of the Sawyer-Man Electric Co. in New York, until just before the works were closed by injunction; and the reputation established by these lamps is an evidence of his ability. He has also made many improvements in his processes, which have been adopted by the Company; and users of incandescent lamps may feel sure of being supplied with lamps that will be high grade. In these days when so many inferior goods are in the market, it will be gratifying to many to know that Mr. Reinmann's conscientious care and thorough knowledge will again be utilized in the manufacture of lamps, and the American Elecl. Manfg. Co. is to be heartily congratulated upon securing his services.

NEW ENGLAND NOTES.

THE EDDY ELECTRIC MANUFACTURING CO., of Windsor, Conn. have just completed arrangements by which they will hereafter be represented in New York by Messrs. H. B. Coho & Co., Mail & Express Building, who will for the present continue at the same address; in New England, by Messrs. G. M. Angier & Co., of 64 Federal street, Boston. Both these firms have for some time past been identified with the Mather Electric Co., and are well and most favorably known in the electrical trade. In addition Mr. S. N. Blake, of Elmira, N. Y., will represent the Eddy Co., in New York state, and altogether the new arrangement promises to be a very strong and successful one. Mr. F. C. Ross, who has represented the Eddy Co. in New York for some years will be connected with Messrs. H. B. Coho & Co. as salesman and so will still retain his interest in Eddy apparatus.

MR. ROBERT C. BROWN has resigned the position of electrical engineer to the Montreal Street Railway Co., to accept that of manager of the Halifax Electric Street Railway, Halifax, N. S. The latter company has a franchise that covers both street railway and lighting. Mr. Brown is at present on a visit to his home here, and will assume his duties at Halifax in a week or two.

NEW YORK NOTES.

THE C. J. FIELD CO., of New York, has been organized with a capital stock of $4,000 to conduct an electrical and mechanical consulting and engineering business. The incorporators and directors are C. J. Field, Frank Bourne and J. W. Gilmore.

THE HICKLEY ELECTRIC LAUNCH & MFG. CO., of Asbury Park, is experiencing a brisk demand for its 16-foot launches recently described in the ENGINEER, equipped with either storage or primary batteries. It is also putting its larger launches into commission for local traffic.

HAMMERSTEIN'S NEW OPERA HOUSE, the "Olympia" is to have a fine electrical plant. The building is situated at Broadway and Forty-fifth street. Hewes & Phillips engines are to be used, and a contract has been made for 600 H. P. of Campbell & Zell boilers, through the Eastern agents, H. D. Bayne & Co., 82 Nassau street.

MR. BENJAMIN E. DAVIS, of Pass & Seymour, of Syracuse, was a visitor at this office this week, and spoke encouragingly of the improved state of trade in his particular line. Mr. Davis is well known to the electrical trade, and has a large number of friends and acquaintances and as he travels nearly all the time, his opinion ought to be worth having.

AGREEABLE AND TIMELY PRESENTS.—The latest summer fad is to present your friend with a fan motor. Such a gift is highly welcome and begets a warmth of sentiment that is in exactly inverse ratio to the physical coolness created. The Interior Conduit and Insulation Co. report that their artistic fans are in brisk demand for this really ingenious and very useful method of giving vent to one's generous feelings. Verbum sap.

MR. HARRY M. SHAW, 136 Liberty street, has been appointed New York manager for H. T. Paiste Co. of Philadelphia, manufacturers of switches, sockets and cutouts. They have a large stock in New York to meet the demands of the trade. Orders for the Eureka Tempered Copper Company's specialties keep Mr. Shaw and his staff busy. His list of these supplies includes Tempered Copper segments, commutators, leaf and gauze brushes and Eureka dry batteries.

STANDARD AIR BRAKE CO. Mr. E. J. Wessels, general manager of the Standard Air Brake Co., leaves to-day (Wednesday) for Europe by the "Rhynland". His departure has already been announced in THE ELECTRICAL ENGINEER by a polyglot card. Preparatory to going abroad and getting on European soil, Mr. Wessels ran up to Canada last week, where he at once sold air brakes for 10 cars, to the Montreal Park and Island Railroad Co. This is the first sale in Canada, though not the first on foreign soil, and is simply another indication of the feeling in favor of better brakes.

WESTERN NOTES.

THE ELECTRIC APPLIANCE COMPANY are making special inducements on flexible switch cords for electric railways and others. They claim to have a superior article at a low price in their Paranite Flexible cable, and to carry one of the largest stocks in the West, enabling them to make prompt deliveries of large orders and special sizes.

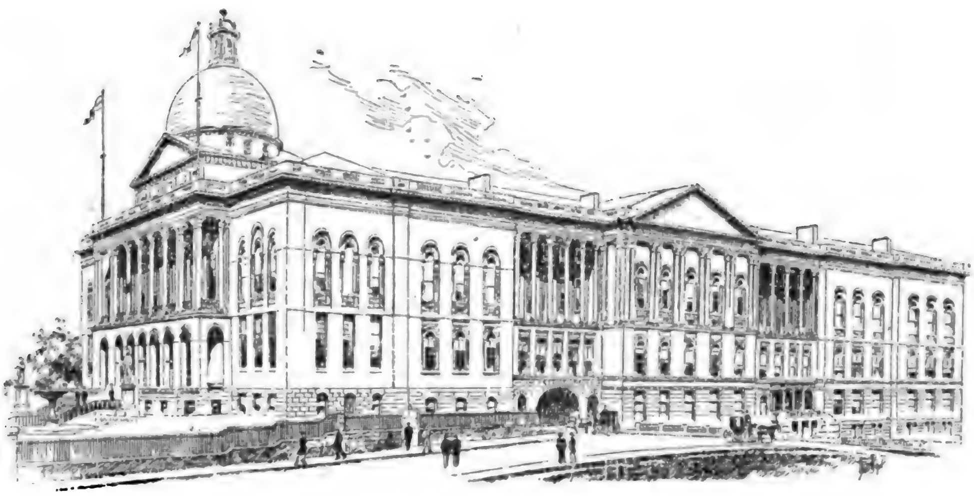
THE METROPOLITAN ELECTRIC COMPANY, 186-188 Fifth Avenue, Chicago, are not complaining about slow business; their sales having multiplied this year three times over the amount at the same period last year. They handle some of the best known specialties on the market; among them P. & B. goods, N. I. R. Rubber Wire, Solar Arc Lamps, Metropolitan Incandescent Lamps, the Portable Hose Bridge, etc.

Mr. W. P. SULLIVAN, who is well known in Chicago, and was formerly connected with the *Street Railway Gazette*, has been appointed Western Manager for THE ELECTRICAL ENGINEER, which asks for the continuance of courtesies and favors in his behalf. Mr. Carl Kammeyer, the efficient incumbent of the office for some time past has resigned to go into engineering work. He has been appointed electrical engineer of the Maywood, Ill., Electric Light Co., and superintendent and electrician of the Bullard Electric Co., of Chicago, which is manufacturing a high grade transformer.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XX. JULY 10, 1895. No. 375.



The New State House of Massachusetts, Beacon Hill, Boston.

THE ELECTRICAL PLANT OF THE NEW STATE HOUSE OF MASSACHUSETTS.

BY

I.

EVERY visitor to Boston is familiar with the aspect of the old State House, whose gilded dome shines not only under the light of every day but in so many pages of history, poetry and fiction. The people are proud of it and its traditions, but proud as they may have been, they have not sought to deny that for many years past the accommodations of the seat of political power and legislation in the old Bay State have been sadly inadequate. The old building that crowns Beacon Hill has long been utterly unable to contain all the State Departments, and hence the movement to which is due the important changes of which this article will speak.

At first it was thought best to take down entirely the fabric of the old State House as designed and built in 1795-7 by Bulfinch, one of the foremost architects in the country in his day, and a Bostonian to boot. Respect for the past, and reverence for the memory of him who designed the far-famed gilded dome, that fetish of every dweller in Massachusetts, forbade any such act of vandalism. The old must not make way for the new; it must stand so long as it would, unsupported, and if the exigencies of modern growth demanded more room, why such improved quarters must assume the form of an annex or extension and be built up to and behind the Bulfinch pile. And thus it was that a compromise came to be effected between those who wanted an entirely new capitol and those who realized the necessity for something being done but insisted on the preservation of the historic edifice. So the undertaking took the form of a very large modern extension, now nearly complete, the finished details of which are a credit to the architect who prepared the plans, and to every firm and individual whose efforts have contributed to make this building one of the notable edifices of the country. It has recently been dedicated to the various uses for which it was erected, and all those whose public positions requires them to frequent it and those who come from afar to examine and admire this noble block, are unanimous in their praise of its comfort and convenience, its luxury and solidity. Massachusetts may well be proud of it; for it is just what was needed, and it is not, in any single detail, too good for the purposes for which it is now being used.

II.

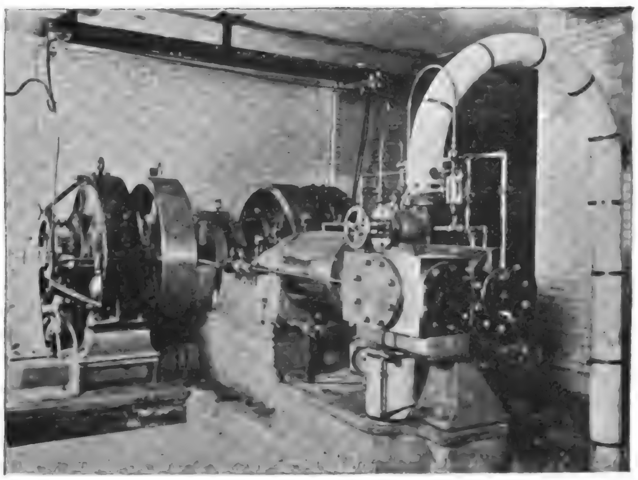
It were too long a story to go into full details of its construction and finish. That would be beyond the province of THE ELECTRICAL ENGINEER, so in this article an attempt will be made to describe the salient features only of the lighting, heating and ventilating plants which have been installed and are now running daily, giving unbounded satisfaction to all.

The electric lighting plant has an aggregate capacity of 8,000 incandescent lamps of 16 C. P. each. The lighting plant is installed in the basement and consists of three compound tandem non-condensing engines of the well known McIntosh-Seymour type. Each of these engines is of 180 H. P. capacity, having cylinders of 13 inches and 19 inches diameter each with 15 inches stroke. They are direct-connected each to two 50 K. W. machines built by the General Electric Co., running at 250 revolutions per minute. These engines were specially designed and finished for this plant, and were installed by Currier, Mayo & Co., Boston, N. E. agents of the McIntosh-Seymour Co. The same firm put in all the steam pipes, etc., etc., of the entire steam plant which in winter will furnish heat to the building. These engines were selected, after keen competition, and they are running both smoothly and noiselessly.

The steam for these engines is produced by two batteries of Babcock and Wilcox boilers, having an aggregate horse power of 830, although it is not all in use as yet. As we have already stated, the aggregate lighting capacity of the plant is 8,000 incandescent lamps of 16 C. P. each, current for which is furnished by six 50 K. W. multipolar iron clad generators, of the well known General Electric type.

III.

In the dynamo room is a large and handsome switchboard of polished white marble, twenty-two feet long and



DIRECT-CONNECTED DYNAMO PLANT, MASSACHUSETTS STATE HOUSE.

nine feet high. This board is covered with all the instruments necessary for operating and controlling the eight distinct circuits which run to every part of the immense building. Provision is made so that one or all of the circuits can be operated with current from their own plant, or can be separately and collectively connected with the Edison company's street circuit should there ever be occasion to do so. The circuits are installed in such manner, that the Senate Chamber, the Hall of Representatives, the various departmental offices, corridors and stairways can be illuminated separately and at will; while there is a distinct circuit for occasional lights here and there throughout the building, for the convenience of the night watchman.

In describing the switchboard a little more in detail it may be said that the main and circuit switches are all of the G. E. type single and double throw, two and three pole, finished in copper throughout and are very handsome. The measuring instruments consist of two main Weston ammeters which measure the total output of all the machines; also ammeter for each separate generator. The main ammeters have illuminated dials, the machine ammeters being of the round pattern isolated plant type.

There are also two Weston voltmeters with illuminated dials, and a portable voltmeter so connected by switch that the insulation of any generator or circuit can be tested out. Behind the switchboard are placed eight Carpenter enamel field rheostats, the handles of which are brought through to the front of the board. There is also a clock, together with steam and pressure gauges, etc.

Each engine is provided with a full height foundation box standing under the high pressure cyclinder and so forming a solid support for the cylinder while at the same time preventing all vibration, thus ensuring that there shall be no jar or noise when the engines are running either on full or light load. All the steam and exhaust pipes with one exception are placed underground, but are very easily accessible, and are covered throughout with non-conducting casing. The lighting throughout is done on the three wire system. The wire used was almost entirely the Okonite brand, there being nearly twenty-five miles of it in all, every yard of it laid in brass armored conduit of the Interior Conduit Co.'s make.

IV.

The various ventilating shafts in the walls, floors and ceilings have been availed of for running the circuits so that if it is ever required to take out a wire and put in another, such change can be easily effected without in the slighest way having to disturb plaster or board.

The dynamo and engine room is finished in white glazed brick and is about the largest and most convenient of its kind in the country. Even the boiler room is light, cool and cleanly, for the boilers are provided with the Roney mechanical stoker, fuel for feeding which is brought on miniature tram cars from the coal bunkers some distance away, while the ashes are removed from beneath the boilers by means of an underground tunnel, so that there is neither dust nor dirt ever to be found in the boiler room, while the occupation of the fireman is not nearly so dirty or so laborious as formerly.

The Star Brass Co. of Boston supplied all the water, steam and vacuum gauges which are placed on a handsome marble board as shown. The Mason Regulator Co. also furnished a number of its high class specialties.

Incidentally it may be stated that the Board of Commissioners appointed by the State to superintend the erection of this new building placed the entire work of designing and installing the electric light plant in the hands of the Massachusetts Electrical Engineering Co., which has installed many of the principal plants throughout New England. That Company prepared the specifications and plans and after the various contracts had been let supervised and thoroughly tested the entire work.

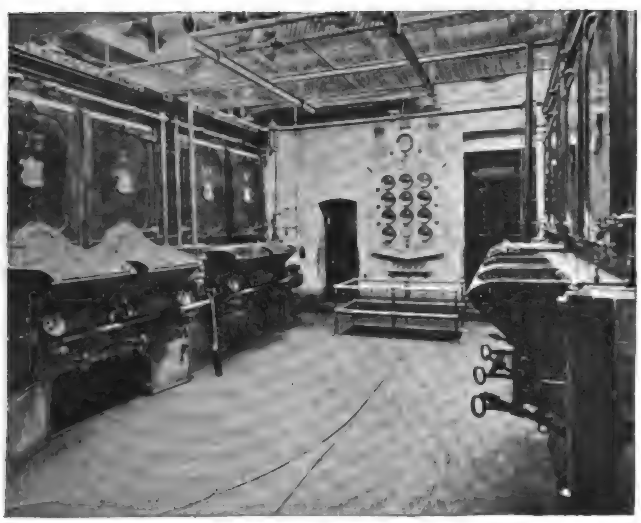
SWITCHBOARD AND GAUGES, MASSACHUSETTS STATE HOUSE.

V.

The electric light fixtures throughout the building call for comment, as they are, in general, of a very artistic character, the arrangement of the lights evidencing both artistic taste and sound judgment in securing good results. In the House of Representatives, in particular, the style

adopted is that of the Renaissance with most excellent results. In this room there is an enormous area to be illuminated. Here upward of eight hundred incandescent lamps have been installed in very effective groups and combinations. The hall is elliptical, and the direct light comes from one hundred and ninety lamps which shed their rays from the upper edge of the frieze, immediately at the base of the beautifully frescoed, vaulted ceiling, and in the centre of which is an immense stained glass sunlight. This corona of light is supplemented by lamps clustered together in richly cut opaque globes set on massive candelabra between the gallery columns and panel pilasters, the galleries extending half way around the ellipse.

These standards or candelabra are very rich designs. Each one rests upon a plinth of malachite. On this plinth rest four massive claws supporting a heavy metallic disc. From the centre of the disc rises a fluted shaft crowned with a handsome capital. Above the capital reach out eight arms at the ends of which are grouped thirty-six lights. There are eight of these groups. On the walls are massive bronze brackets each one supporting a number of lamps in richly chased globes. Similar taste and elegance is seen in the Senate Chamber as well as in the various rooms used by the legislators and the offices set



BOILER ROOM WITH MECHANICAL STOKERS.

apart for all the officials of the State. The fixtures throughout were supplied by the well-known Boston firm of McKenney and Waterbury, who have equipped many of the chief public buildings throughout New England.

As is the case in the erection of all modern buildings, the subject of heating and ventilating the new State House engaged the best thought and judgment of experts, and Professor S. H. Woodbridge, of the Mass. Institute of Technology, has succeeded admirably in these two important departments. He it was who designed most of the apparatus and who supervised its construction and installation.

VI.

The heating and ventilation is effected by means of two distinct sets of apparatus. The direct heating is by means of radiators placed under the windows in each room, and concealed by ornamental screens. These radiators are fed by the single-pipe system from main pipes hung in the roof space. Each radiator is automatically controlled by an electric thermostat, so that the steam is shut off when the temperature of the room reaches a certain point, say, 70 degrees.

The ventilation is by the "Plenum" system, two large fans, 12 and 10 feet in diameter respectively, installed in the basement and run by two 15 H. P. electric motors of the well known C. & C. type, supplying the fresh air, while the vitiated air is exhausted by means of one 7½ H. P., one 5 H. P. and one 3 H. P. C. & C. motors installed and connected with fans in the main roof of the building.

Ample provision has been made for warming the fresh air in winter time before it is distributed. This is accomplished by forcing the air through coils consisting of hundreds of pipes heated by steam, which is supplied from the boiler plant, the same boilers furnishing steam for heating the building throughout as well as for running the electric plants, pumps for elevators, etc., etc. The heating and ventilating plant was wholly built and installed by Mr. Albert B. Franklin, a well known engineer of Boston.

The elevator system was constructed by the Whittier Machine Co., Boston. The shafts are operated by hydraulic power throughout. The pumping apparatus is of the well known Worthington type, and consists of two compound duplex pumps, each of 3,000,000 gallons capacity, they being the largest pumps for elevator service now in use in New England. There are also three other pumps of the same make which are used for returning the water for condensation. Four Worthington water meters are in use, these measuring the water used in the entire building, and are of special design.

A very ingenious device which is operated by electricity is the dumb waiter or hoist in the State House Library. It was suggested by the librarian and built and installed by the Elektron Mfg. Co. This apparatus is used for transferring books from the different floors of the "stack room," and is controlled by a set of push buttons at each of the four landings. There are three buttons in each set—one to send the car up, one to send it down, and a third to stop it while running in either direction. A small Elektron motor furnishes the running power.

From the foregoing details and descriptions it will readily be appreciated that here as elsewhere, in the equipment of public buildings, where, presumably, there would seem to be least call for electrical or steam power plants, these two subtle forces have been made to play most important parts. The occupants of this extensive building go about their daily duties, winter and summer, enjoying the most agreeable comfort, subjected to no ill effects from over cold or over hot rooms; breathing every moment pure air which comes to them exactly as it will best conduce to health and pleasure.

ELECTROLYTICAL PROCESS OF BLEACHING.

In a recent review on progress in bleaching in *Lehne's Färberzeitung*, Dr. Kielmeyer mentions an electrolytical process invented by Dr. Karl Kellner. The necessary apparatus consists of a pair of rollers—the one iron, the other carbon—which, while rotating, are fed with an electric current by contact with wire brushes, and are thus converted into the two poles of a battery. The cotton cloth before passing these rollers is saturated with brine and runs in company with an endless felt blanket, also saturated with brine, which is next to the iron roller and receives the caustic soda formed, to deliver it further on into a tank filled with salt water. The chlorine liberated at the carbon roller accumulates in the cotton fabric. On issuing from between the rollers (whereof there may be several pairs) the cloth remains rolled up for some time before it is washed to prolong the bleaching process.

UNIVERSITY OF WISCONSIN.

The College of Mechanics and Engineering in the University of Wisconsin has published its announcement for 1895-96. The corps of instruction of the college shows an imposing front, and among the special lecturers appear such names as Alexander Graham Bell. The course at the collage is based on the idea of a thorough-going fundamental training in which the practical and the theoretical are equally combined. The Electrical course has been prepared with excellent judgment.

THE ACTION IN THE BOYNTON MULTIVOLT BATTERY.

BY

Wm. A. Anthony.

I notice in recent issues several communications in relation to the Boynton multivolt cell. Mr. Johonnot in the ENGINEER of June 12, attempts to give the theory of the battery and ignores entirely the fact that there are potential differences between the several carbons and also between the several zincs, as well as between zinc and carbon; and his theory, therefore, leads him to totally erroneous conclusions.

Prof. Carhart, in the same issue comes much nearer the truth, but in stating that "the most important leakage or waste current is between the zinc of cell 1 and the carbon of cell 3" (see accompanying Fig 1), he overlooks the E. M. F. of the cell. There is a difference of potential between the carbon of cell 1 and the zinc of cell 1, the

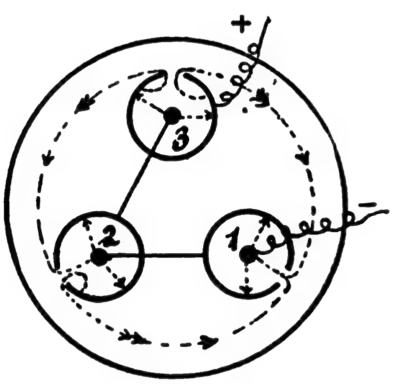


FIG. 1.

carbon being +, and yet, when the cell is in action, current flows through the liquid *from zinc to carbon* against the potential difference. There is, therefore, no greater *effective* potential difference between the zinc of cell 1 and the carbon of cell 3, than between the carbons of those two cells.

It is true that I did not allude to the fact that with a low external resistance the leakage would be small, but with a low external resistance this battery would be a very inefficient combination. The elements for such use should be joined in multiple and not in series. When

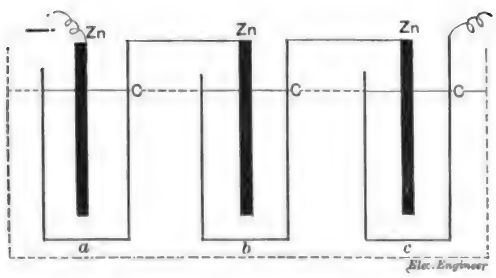

FIG. 2.

joined to produce a "multivolt" battery, its purpose would be to overcome a considerable resistance.

Now as to the leakage, let the connections between the different elements be broken and the resistance of the liquid from carbon to carbon, just as they stand, be measured. From the data given in the description of this battery in the issue of May 15, that the E. M. F. on open circuit was $5\frac{1}{4}$ volts and the current on short circuit 5 amperes, I deduce the resistance from carbon to carbon as equal to about 3 ohms.

Referring to my figure page 484 of May 29, which is reproduced here in Fig. 2, would it be considered good practice to connect the first and third carbons of a battery of three cells by a wire of 3 ohms resistance as shown by the dotted line, *a b* Fig. 3? Yet this is exactly what is done when the three elements are immersed in liquid in one cell. And what is gained by it? Nothing, except the facility in handling a gallon or two of liquid contained in one cell instead of three; and I venture to say,

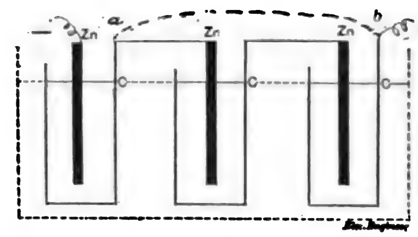

FIG. 3.

in consequence of the local actions, it will need to be replaced twice as often in the one cell.

I arrive at the resistance given above as follows. The E. M. F. of a zinc-carbon bichromate cell is given as more than 2 volts. The potential difference between the terminals of a battery of three well insulated cells in series would on open circuit be more than 6 volts, whereas the Boynton cell gives only $5\frac{1}{4}$ volts. This loss is due to the short circuiting effect of the leakage upon two of the cells, exactly as would occur if a conductor joined the points *a* and *b*, as shown by the dotted line in the figure. Assuming the full potential difference of 2 volts for the last cell, the two short circuited cells give only $3\frac{1}{4}$ instead of 4 volts, and this would be the case if the short circuit was a little less than four times the internal resistance of the two cells. It is stated that the battery on short circuit gives about 5 amperes; this means that its internal resistance is about 1 ohm, that is, $\frac{1}{3}$ ohm per element. Four times the resistance of two cells would be less than 3 ohms for the leakage path. This seems small if the outside of the carbons is perfectly insulated, but it cannot be far from the truth unless I have overestimated the E. M. F. of the element. If this leakage path has such a low resistance it means a leakage current of 1 ampere,—as large as the useful current that should be taken from a battery of such dimensions if it is to be used with any regard for efficiency.

LIGHT AND ELECTRIFICATION.

PROFESSOR LODGE contributes an interesting article to this month's *Science Progress* on photo-electric action, or the effect of light in facilitating the discharge of statically charged conductors. This is virtually a new branch of physics originating from an experiment of the celebrated Hertz, the influence of whose discoveries is now being felt in many departments of electrical science. Hertz observed that the sparking of an induction coil was facilitated when the light of another spark fell upon its secondary terminal. Further experiment showed that this effect was due to the ultra-violet rays, and that the neighborhood of the negative pole was the most sensitive part of the spark gap. It appeared from this that negative electricity would be more readily discharged than positive, and this was found as a rule to be the case. If ultra-violet light is allowed to fall upon a freshly scraped zinc disc forming the cap of a negatively charged electroscope, the charge will leak rapidly away. The most effective metals were found to be the alkalies, such as potassium and sodium, and the least effective, the noble metals, such as gold and silver. It was found, in fact, that if metals were arranged in the order of their facility for discharging negative electricity, they took the order of the voltaic series, a fact which indicated that electro-chemical action had something to do with the effect. Elster and Geitel, by the use of polarized light, showed that oscillations of light waves, perpendicular to the surface of the metal, produced a more rapid discharge than those parallel to it. The dissociation of molecules which is now considered to accompany the breaking down of electric strain, would appear from these experiments to be facilitated by light vibrations when applied in the direction in which the ions travel.—*London Electrical Review.*

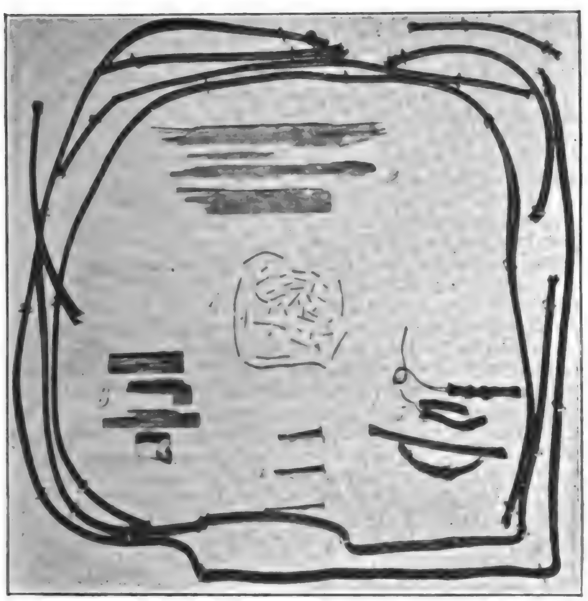
A SINGULAR EFFECT OF LIGHTNING STROKE IN CHICAGO.

BY

H. M. Stine

On Sept. 7, 1894, lightning struck the factory building of the Illinois Industrial Home for the Blind. But slight damage was done to the building, though some of the effects on the electric light wires were most singular.

The writer is indebted for the facts here noted, to Mr. Thomas Appleton, civil engineer, of Chicago, who was the Superintendent of Construction for the building. The Industrial Home is located on Douglas Boulevard, Chicago, the factory building being near the C. B. & Q. tracks. In his report to the Board of Trustees, Mr. Appleton states: "During the storm of last Friday night the chimney of the factory was struck by lightning, and about six feet of the south side of the chimney knocked down. The lightning also entered the room in the southeast corner of the upper floor, and destroyed some 50 feet of insulated wire, one drop cord and pendant, and the switch box. A large sliver was knocked off from the lower side of one of the roof beams, and it was a wonder the roof was not set on fire. Probably the whitewashing of the beam hindered the kindling of a fire at this point."



EFFECT OF LIGHTNING STROKE ON INTERIOR WIRING.

The roof beams were anchored by iron plates spiked onto the sides of the beams and extending through the wall with large cast iron washers outside the brick. The electric light wiring was open, cleated work, and was carried around the beams near the anchor plates. The lightning apparently struck an anchor plate and passed from this to the wiring. It knocked a near-by switch-box to pieces, breaking the porcelain fixtures and burning the screws. The upper screw of group 4 in the illustration shows the iron near the end melted out, leaving only the thread, like a spiral spring. Group 3, is a splintered oak cleat; while group 2 shows some slivers knocked off the beam.

The effect of the lightning on the wires is the singular part of the case. The outside diameter of the wire was $\frac{3}{16}$ inch, the conductor being No. 14 A. W. G. Around the conductor was a soft layer of white rubber; over this a layer of black rubber which was covered with the usual protecting layer of braid. The insulation was heavily coated with compound and finishing varnish. About ten feet of the insulation is shown in the illustration, for it is only a tube, the wire for the most part having disappeared, except between the letters B, C and D. Group 5 shows damaged pieces with the conductor present, though badly burned. The outside of the insulation in many places plainly shows the effect of heat; the varnish has disappeared and most of the compound melted out. At irregular intervals there are openings or ruptures. A few feet was split open and the rubber core found intact and only in a few places did it show traces of burning. There were scarcely any traces of copper markings that would indicate the wire had been vaporized. After the accident the conductor was found scattered about the floor. For the most part the pieces were from one-fourth inch to three-fourth inch in length and quite regular. Group 1 shows a number of these pieces. The wire seems to have been literally shot out from the insulation as from a gun. The uniformity of length of these pieces is significant. When a long piece of fuse wire is blown it invariably breaks into a number of pieces of quite uniform length. The two cases seem quite similar and indicate in a manner some form of rhythmic action. The faces of the ends in both cases are square and crystalline. This would suggest that the copper conductor was fused internally but cooled rapidly when exposed to the air. Only a few of the pieces are pitted and badly burned. An occasional piece of wire was found in the inner tube, but they were of uniform length with those that had been ejected.

AN IODINE VOLTAMETER.[1]

AFTER referring to the usual methods of determining the value of the small currents used in calibrating galvanometers and other apparatus for measuring small currents, and discussing the errors to which they are subject, the author gave his reasons for selecting iodine. He did this since with the exception of mercury in the mercurous state, iodine has the largest electro chemical equivalent, and, in addition, by titration with sodium thiosulphate it is possible to determine the quantity of iodine liberated with a greater accuracy than can be obtained by weighing a deposit of copper or silver with the balance. The solution employed in the voltameter contains 10 to 15 per cent. of zinc iodide. If care is taken to leave a small piece of metallic zinc in this solution no free iodine is liberated on keeping, unless the solution is exposed to a strong light for some time. The anode consists of a plate of platinum at the bottom of a tall and fairly narrow beaker. The wire leading the current to the anode is incased in a glass tube so that the iodine is only liberated at the bottom of the beaker, where, on account of its great density, it tends to collect. The cathode consists of an amalgamated zinc rod which, to prevent loose particles of zinc falling down into the iodine, is surrounded by a piece of filter paper or vegetable parchment. In an electrolysis lasting for as long as two hours none of the iodine is found to diffuse up to the part of the solution near the zinc cathode. Where, on account of the extreme feebleness of the current employed, it is necessary to allow the electrolysis to continue for longer and have two hours, a U-tube is used with two small plugs of asbestos at the bend, the anode being in one limb and the cathode in the other. With this form of voltameter, even after the current has flowed for several days, no signs of iodine have been found in the limb containing the cathode.

On account of the production of electric convection currents, the iodine voltameter does not seem to be quite so suitable for accurate measurements of strong currents. After the current is stopped the zinc electrode is immediately removed, the solution stirred, and the amount of iodine liberated determined by titration with sodium thiosulphate. The author finds that a convenient strength of the thiosulphate solution is one in which 1 cc. corresponds to the amount of iodine liberated by 5 coulombs of electricity. This solution contains 12 8375 grms. of pure recrystallized sodium thiosulphate per litre. It is possible to perform the titration to within 0.1 cc., which corresponds to 0.5 coulomb, or if the electrolysis lasted one hour, to $\frac{1}{7200}$ ampere. In a comparison made with a silver voltameter, the current as deduced from the silver was 0·0264 ampere, and that deduced from the iodine 0·0266. The author considers that part of the difference may be due to the effect of oxygen dissolved in the solution of silver nitrate.

EXPERIMENTS ON THE ELECTRIC DISCHARGE.

The London *Electrical Review* gives excellent reproductions of some of a remarkable series of photographs and dust figures produced by the action of very powerful electric discharges, which were exhibited on the lantern screen by Lord Armstrong at the last conversazione of the Royal Society. Most of the effects were obtained by the use of a large multiple Wimshurst machine, having 16 plates of 34 inches diameter, made by Newton & Co., and capable of giving a spark of about 17½ inches. The machine was fitted with two 10-gallon Leyden jars, as condensers, and was found perfectly adapted for the purpose of the experiments. The photographs were mostly obtained by the well-known method of causing the discharge to pass over the surface of a photographic plate with which the electrodes had been placed in contact. The dust figures were produced by discharging on glass or metal plates over which had been sifted various more or less non-conducting powders, such as calcined magnesia mixed with carbon in the form of lamp-black, tripoli powder, and hard carbon reduced to a fine powder. Many of the pictures were most suggestive, and it is not improbable that they may lead to advances in the knowledge of molecular physics, and of the true nature of electricity.

1. Abstract of a paper read before the Physical Society, May 10, by M. Kerroun.

ELECTRIC POWER IN FACTORIES AND MILLS.[1]

BY F. B. CROCKER, V. M. BENEDIKT AND A. F. ORMSBEE.

The application of electric power distribution to the operation of factories and mills, including the driving of the various machines and other apparatus, is the latest and one of the most important problems toward which attention is now being directed, the question being one of extreme prominence both from an economical as well as from an engineering standpoint.

In comparing two or more different systems of power distribution, the fundamental basis of comparison is generally that of dollars and cents. This is certainly correct, as far as it goes, but unless a very decided difference be found between the costs of running under the various systems, it may be found that other factors enter; factors which cannot be estimated in dollars and cents, namely, questions of desirability and convenience. Without considering any tests whatever, there are several exceedingly advantageous points in the use of motors in factories which are almost self-evident, such as: 1. Clear and unobstructed passages and head room, the latter facilitating the use of travelling cranes. 2. Ease of shifting the tools from place to place, possibly necessitating the placing of a starting box and the putting up of a little extra wire, as compared with the inconvenience and trouble of setting up and adjusting a line of shafting, hangers, belts, etc. 3. The economy due to the ability to run a single tool without necessarily starting the whole factory or at least a complete section. 4. The running expense is entirely stopped when the tool is shut down. 5. The absence of the drip of oil from overhead shafting. 6. The tools may be placed at any desired points almost regardless of the distance. 7. It is not necessary to arrange the tools parallel as in the mechanical system. 8. A wider range of speed is possible. 9. Less damage caused by a fuse blowing than by a belt slipping off in case of accident or excessive load.

Considerations like the above have great weight in deciding a question such as that under discussion, and there is no doubt whatever that in most cases they rise to such prominence that they warrant a complete change from the old system to the new, even though there is no gain in economy or increased output. In most cases, however, it has been conclusively shown that considerable saving and increase in production is obtained, one test showing a very considerable percentage of increase in the output. The partial, if not the complete, displacement of the old method by the new is only a question of time, and it was the appreciation of this fact that induced the authors to undertake the determination of the power actually required to run the various tools and machines as used in ordinary practice.

The authors then give a description of a series of practical tests carried out at the works of the Crocker-Wheeler Electric Co., at Ampere, N. J., and at those of the De La Vergne Refrigerating Machine Co., at Port Morris, N. Y. The results are given in the following table:—

TESTS AT THE CROCKER-WHEELER FACTORY.

No. of Test.	Size of Motor.	Number of tools driven by motor.	Average Amps.	Average H. P.	Remarks.
1	1.5 H. P.	1 boring machine,	8.3	1.23	
2	1. "	1 drill press.	2.85	.42	Less than ½ full load of motor.
3	1. "	1 " "	2.86	.42	
4	1. "	1 " "	1.9	.28	
5	1. "	1 punch press.	4.86	.71	
6	1. "	1 gang drill.	4.75	7	Drilling ¼ in. and ⅜ in. holes.
7	3. "	2 machines.	10 04	1.48	
8	1. "	6 "	5.86	.86	All small machines.
9	3. "	7 "	13.36	1.97	
10	3. "	8 "	9.92	1.46	
11	7.5 "	2 "	33.1	4.87	Required 2.3 H. P. to run shafting only.
12	10. "	20 "		4.78	Tested by watt meter.
13	3. "	5 "	7.0	1.08	
14	3. "	1 engine lathe.	11.4	1.68	Light cut taken by tool.

TESTS AT THE DE LA VERGNE WORKS.

1	15. H. P.	1 planer.	20.08	5.11	Planer 10 in. x 9 in. x 22 in. Voltage 190.
2	5. "	1 drill press.	4.07	1.23	⅞ in. drill. Voltage 215.
3	10. "	1 boring tool.	14.47	4.17	Voltage 215.

The results obtained in these tests show that the power required to drive machine tools has been considerably overestimated, for it will be noted that with a large majority of the tools tested, the motor was not more than one-half loaded, and in these cases it was seldom that the load equalled the full power of the motor, even for an instant. In the case of the large planer, although the motor was overloaded 50 per cent. upon reversal of the bed, the average load was only one-third of the rated full load. With this machine, however, when the piece of work is very short, necessitating more rapid reversals, the average load will be much nearer the most economical output of the motor.

The question of running machine tools by individual motors or grouping a number of machines together and driving them by one motor, does not seem to allow of a general solution. It would not be advisable, for example, to use the individual system where there are a number of small tools, each one of which requires only a small fraction of a horse-power. On the other hand if we have a large tool that requires considerable power, it would seem to be far more economical to run it by a single motor, using as little belting and shafting as possible.

The introduction of the electric system of distribution of power in the cotton industries of New England is now fairly begun. Although there are no large mills driven entirely by this system, a number of them have an electric plant and certain sections of the mill are driven by motors. An electric plant was installed four or five years ago in the works of the Silver Spring Bleaching and Dyeing Co., at Providence, R. I., but it was intended chiefly for lighting. But motors were placed in the carpenter and repair shops, and several other places, until at present there are about 100 H. P. of motors installed in eight units.

A visit was made to the works of the Donnell Manufacturing Company, at Pawtucket, R. I., where a very fine electric plant has very recently been installed to drive the calico printing machines. The problem of running this class of machinery by electric motors has been a very difficult one to solve, for the motor must be capable of running at a number of different speeds and running constantly at any given speed with a variable load. In this case it has been solved by the use of a modification of the Leonard system of motor regulation. The outfit for each printing machine consists of a motor and a dynamo of the same size, the field rheostat of the dynamo being placed alongside the printing machine. The speed of the motor is thus changed by varying the voltage of the particular dynamo which supplies it with currents.

This plant has been completed but a short time, and it was not possible to obtain any accurate figures showing the power used by the motors under various conditions of speed and load. Formerly the machines were run by individual engines and much difficulty was experienced in starting them, as the pressure of the printing rolls against the cloth is so great. With electric motors this difficulty is overcome, as the motors will stand a very heavy overload for a short time, and the starting torque is very great. The great advantage of the electric system as here used is not so much in the saving of power as in the convenience to the workmen, and hence the increased production.

Although this plant has been in operation only a short time, it is claimed by those in control that the production is materially increased. In a paper by Mr. S. B. Paine in *Power*, June, 1895, he states that the increase in the production amounted to more than 25 per cent., and that the quantity of "seconds" (inferior product) was also considerably reduced. This is very important as the men in charge of printing machines are skilled workmen of the higher order and a small saving in wages for a given production is of more value than a considerable saving of power.

A visit to Baltic and Taftville was also made to see the practical working of the well-known power transmission plant between these places. At Taftville, where the Ponemah mills are located, there is not sufficient water power to drive all the machinery, so an electric plant was installed at Baltic, 4¼ miles up the river where a dam had been built, giving an available head of 34 feet.[2]

First Cost.—Practically the only objection which can be urged against the electric system is the fact that the first cost of installation is greater than with ordinary belting and shafting, but even this is questionable since the authors know of cases in which the estimated total cost of installing the necessary belting and shafting was actually greater than the equivalent electric motor outfit. The electric system would be cheaper for example in the case of very long or scattered buildings or those containing many stories or rooms, in any of which cases the belting and shafting required would be very complicated and expensive. The use of belting and shafting requires a much stronger and more expensive roof or ceiling than the electric system.

Saving of Power.—It might seem that the electric system would actually consume more power than the ordinary plan since it involves two transformations of energy. In most cases, however, if the power has to be distributed to a number of machines, particularly if they are located at any distance from the engine, the loss of power is less with electric transmission. This is explained by the high efficiency of the dynamo and motor compared with the low efficiency of belt transmission as ordinarily practiced, involving as it often does very imperfect alignment and lubrication of the shafting. Perhaps the greatest saving, however, of the electric system is due to the fact that the consumption of energy entirely ceases when the tool stops. This

1. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

2. See illustrated description of this plant, THE ELECTRICAL ENGINEER, May 2, 1894.

stoppage in the case of the busiest tools amounts to at least 25 per cent. of the nominal working hours throughout the year and with large or special tools which are not used so steadily, the stoppage is often as high as 50 to 75 per cent. since there are many whole days when they are not used at all.

Idleness due to strikes as well as to slack times must also be considered and would usually amount to quite a large percentage in ten years for example. This assumes, of course, that a portion of the shop is running, which is usually the case even under such conditions. In short with the mechanical system there is an enormous amount of shafting, idle pulleys and belting which runs for long periods of time doing little or no useful work, but consuming considerable power.

Wherever electric motors can be substituted for a number of small engines scattered about, the saving in power is very great not only because of the low efficiency of small steam engines, but also by the avoidance of condensation in long steam pipes.

Increased Output.—This is, perhaps, the most important advantage gained by the electric system since after all the cost of power is a very small item, being, according to Mr. Richmond,[1] only about 1 per cent. of the wages paid in average machine shop practice. This increased output is secured by the greater convenience and promptness in starting and stopping as well as in regulating the speed of the machinery. The workman can, for example, temporarily increase the speed when the conditions are favorable, thereby saving considerable time.

Flexibility.—The great convenience of moving the tools and placing them in any desired position is another great advantage of the new system. The great adaptability of this system is particularly well shown in the case of a factory which was almost completely destroyed by fire, nevertheless a few uninjured tools in a remote end of the building were operated successfully by means of electric motors within two days after the fire.

Speed Regulation.—The ordinary type of motor used in factories is the plain shunt wound machine fed with constant potential current. The motor is started and varied in speed by means of a rheostat in the armature circuit. This simple arrangement answers very well in most cases, but for variable speed between wide limits a series wound motor controlled by a rheostat as in electric railway practice may be preferable. In other cases some special method of regulation such as the Leonard system, or the "boost and retard" plan, may be adopted.

THE COST OF STEAM POWER.[2]—II.

BY CHAS. E. EMERY, PH. D.

Previous articles of the writer on this subject dealt with the problem as it practically presented itself at the several times. The first article in 1883[3] referred particularly to results which had been obtained in a number of typical cotton mills by the use of the ordinary condensing engines in vogue at the time. A more recent article in 1893[4] discussed the question of the cost of steam power in 500 H. P. units or multiples of the same developed in different kinds of engines, including the more modern triple compound engines. The first paper was based on actual conditions, the second on assumed conditions, the best experimental results being considered, but afterward modified by judgment so as to give a final result which would approximate the conditions of ordinary average working. In a later and more general article published in 1895[5] the method employed to increase experimental results to an approximately practical basis was outlined, but otherwise the inquiry was extended little or no further than before.

In connection with the proposed supply of power in large units from Niagara Falls and other undertakings of a similar character, the question naturally arises: What would be the cost of steam power if also supplied in large units and generated with modern machinery of the most approved type? The question would be a simple one if it involved only the amount of coal consumed at a definite price, and the labor required to handle the coal and attend to the machinery. It is very common to compare the value of two engines simply by the relative amount of coal consumed, assuming that other costs incident to the development of the same power will be the same in all cases. Even if the assumption be substantially correct it has a more important bearing on the result than appears at first sight. The cost of coal is for ordinary engines of moderate size only about one-third of the total cost of steam power, so, if the other costs remain nearly constant, moderate savings in the cost of coal will not proportionally decrease the cost of the power.

The size of the units is limited by the conditions. If 20,000 H. P. as a maximum were to be delivered, two units of 10,000 H. P. each would do the work, but evidently the spare engine would require also to be 10,000 H. P. and this would involve too large an amount of capital in spare machinery. At Niagara Falls five connected turbines and dynamos of 5,000 H. P. each are being erected in a preliminary plant so that only 20,000 H. P. maximum can be delivered if one unit is held in reserve.

The average cost per H. P. when the load is variable is considerably greater than if the power be furnished continuously. It is desirable at the outset, however, to ascertain what steam power will cost under the most advantageous conditions as to demand, and we therefore submit a preliminary estimate based on the assumption that 20,000 H. P. can be sold for every hour in the year.

TABLE I.

SHOWING COST OF STEAM POWER ON BASIS OF GENERATING 20,000 H. P. CONTINUOUSLY EVERY HOUR IN THE YEAR.

			Per Cent. of Total Cost.
	Yearly cost of coal for 20,000 net H. P. operated continuously every hour in the year, based on a consumption of 1.25 pound of coal per indicated H. P. per hour. Cost of coal assumed at one mil per pound, or $2.24 per ton.		
1.	Engine efficiency assumed at 92.3 per cent.	$237,950	43.4
2.	Estimated cost of labor	60,444	11.1
3.	Estimated cost of supplies and regular repairs	105,190	19 2
4.	Estimated interest, insurance, taxes and cost of renewals	144,000	26.3
5.	Total	$546,814	100.0
	Which divided by 20,000 gives the following:		
6.	Cost of steam power per H. P. per year, on a basis of 20,000 H. P. delivered every hour in the year	$27.34	
7.	Cost of steam power per H. P. per year on above basis, if 5 per cent. of the original cost of plant be charged for dividends, and $1.00 per H. P. added for general business expenses, 27.34 + 3.60 + 1.00 =	31.94	
8.	Cost of steam power per H. P. per year on above basis, if 10 per cent. of the original cost of plant be charged for dividends, and $1.00 per H. P. added for general business expenses, 27.34 + 7.20 + 1.00 =	35.54	

This cost is lower than it is probable any plant can be operated under commercial conditions. This price is somewhat higher than those given in the papers previously mentioned, simply because operation is supposed to be continued every hour in the year.

We, therefore, assume that the power will be produced regularly for 1¼ pounds of coal per indicated H. P. per hour which would be obtained with engines requiring 12½ pounds of feed water per H. P. if the boilers evaporated 10 pounds of water per pound of coal, or if the boilers evaporated 9.6 pounds of water per pound of coal and the engines only required 12 pounds of water per H. P. per hour. For permanent work of the kind assumed, engines of comparatively slow speed should be selected and, although some of the work might be directly connected, part of it at least would necessarily be operated by some method of transmission. The frictional losses of the engines and the more important features of transmissiom to the work done have been assumed at 7.69 per cent., so that the amount of coal per indicated H. P. above assumed must be increased by $\frac{1}{13}$ to give the coal per net H. P.

The best quality of coal will cost but little over $2 per ton if purchased in large quantities, though this price must be increased on the seaboard fully 75 cents, and for ordinary consumers, of course much more. The price upon which comparison has been made is one mil per pound or $2.24 per ton, to include the cost of delivery directly in front of the boilers. The cost in line 1, Table I, is derived simply by multiplying the net power, 20,000, by 1¼, the coal per indicated H. P. adding $\frac{1}{13}$ to allow for friction, and multiplying the result by 8,760, the number of hours in the year, and $0.001, the price per pound.

The total cost of such a plant cannot be determined accurately in advance. The present prices for steam machinery are very low and it might be possible to buy engines of the best type with necessary boilers, ready for erection for $30 per H. P. To this price, however, must be added the cost of the land upon which the plant is to be erected, the cost of foundations, of erection, of the buildings, of the chimney, the pipe connections, the general means of transmission, and the multitude of minor details required for fitting up such a place ready for use. The probable cost has been fixed at $64 per H. P. and as at least ⅛ surplus power will be put in the station there will be required a steam plant of 22,500 H. P. which at $64 will cost complete $1,440,000, 10 per cent. of which as required above is written in line 4.

Referring to line 6, we find that the "Cost of steam power per H. P. per year on the basis of 20,000 H. P. delivered every hour in the year" is $27.34. The price at which this power can be sold to consumers will depend upon the way the company furnishing the power is organized. The interest on the cost is already provided for in line 4, so the net cost given, viz.: $27.34, would be that chargeable to power if the same company that built the works used the power, or if an association of individuals should build the plant and simply charge themselves with its cost.

If, however, a private company with ample means should build the plant on a cash basis and wish to sell power and realize a return of 5 per cent. on first cost, independent of interest on the money invested, the modified cost would be $27.34 plus 5 per cent. of 64 × 1⅛ = $72, viz.: $3.60, to which should be added, say $1 per H. P. for general business expenses, making the total charge $31.94 shown in line 7, Table I., the same method being used in reference to similar lines in Tables II. and III.

1. *Engineering Magazine*, January, 1895.
2. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26, 1895.
3. Trans. Am. Soc. C. E. vol. xii., p. 425, Nov. 1883.
4. Trans. Am. Inst. El. Engrs., vol. x., p. 119, March, 1893.
5. *Engineering Magazine*, vol. viii, p. 796, Feb. 1895.

If, however, the promoters desired 10 per cent. profit on original cost or a proportionally less percentage on stocks and bonds issued in excess of first cost, the modified cost per H. P. per year would be $27.34 plus 10 per cent. of $72, viz.: $7.20, to which adding $1 per H. P. as before for general expenses gives as the total charge under these conditions $35.54, shown in line 8, Table I., the method applying to Tables II. and III.

We are now prepared to ascertain the variations in result which would be produced if the power were considered variable. For this purpose let us assume there will be sold :

	Daily H. P. Hours.
1. 20,000 H. P., 10 hours per day	200,000
2. 12,000 H. P., 10 hours per day	120,000
3. 5,000 H. P., 4 hours per day	20,000
4. Total daily H. P. hours	364,000

which would probably be required on, say, 309 working days in the year.

5. Total H. P hours, 309 days	105,060,000
Then if 5,000 H P. were required for the remaining 56 days in the year:	
6. Total H. P. hours 56 days of 24 hours, 5,000 H. P	6,720,000
7. Total H. P. hours per year	111,780,000
Average H. P. per hour during the year:	
8. Previous result + 8760 =	12,760 H. P.

The average H. P. is therefore 63.80 per cent. of the maximum. This percentage is frequently termed the "power factor," and is rather higher than has been found in practical cases heretofore. An estimate of the cost on this basis is given in Table II.

TABLE II.

SHOWING THE COST OF STEAM POWER ON BASIS OF GENERATING 20,000 H. P. MAXIMUM AND AN AVERAGE OF 12,760 H. P. FOR EVERY DAY IN THE YEAR.

		Per cent. of total cost.
1. Yearly cost of coal	$157,644	37.3
2. Estimated cost of labor	47,652	11.3
3. Estimated cost of supplies and regular repairs	73,584	17 4
4. Estimated interest, insurance, taxes and cost of renewals.	144,000	34.0
5. Total	$422,880	100.0
Which divided by 12,760, the average H. P., gives the following:		
6. Cost of steam power per H P. per year on basis of delivering 20,000 H. P. maximum and an average of 12,760 H P. for every day in the year		$33.14
7. Cost of steam power per H. P. per year on above basis if 5 per cent. of the original cost of plant be charged for dividends and $1 per H. P. added for general expenses, 33.14 + 3.60 + 1.00 =		$37.74
8. Cost of steam power per H. P. per year on above basis if 10 per cent. of the original cost of plant be charged for dividends and $1 per H. P. added for general expenses, 33.14 + 7.20 + 1.00 =		$41.34

The cost of coal is made up as follows: By reference to the above it will be seen that 15,000 H. P. of boilers out of 20,000 must be shut down daily for periods varying with the demand, and it is considered that it will require an amount of coal equal at least to the average consumption for one hour during regular operation, to maintain banked fires, overcome radiation and bring the fires to average working condition when they are again put in operation. The total daily H. P. hours in line 4 is therefore increased 15,000 and multiplied by 309; the horse-power hours for the 56 holidays, line 6, are then added to the same; the sum multiplied by 1.25 pounds of coal per H. P. and by one mil per pound and one-twelfth added to the whole for friction, which gives the result written in line 1, Table II.

A large proportion of the power in manufacturing establishments is used only 10 hours per day, so this investigation would not be complete if it did not include a presentation of the cost of steam power generated with large units for 10 hours per day. Such an estimate is made in Table III.

TABLE III.

SHOWING THE COST OF STEAM POWER ON THE BASIS OF GENERATING 20,000 H. P. CONTINUOUSLY FOR 10 HOURS PER DAY FOR 309 DAYS IN THE YEAR.

		Per cent. of total cost.
1. Yearly cost of coal	$92,056	30.6
2. Estimated cost of labor	27,198	9.1
3. Estimated cost of supplies and regular repairs	37,080	12 3
4. Estimated interest, insurance, taxes, and cost of renewal	144 000	48 0
5. Total	$300,334	100.0
Which divided by 20,000 gives the following:		
6. Cost of steam power per H. P. per year on the basis of delivering 20,000 H. P. continuously for 10 hours per day for 309 days in the year.	15.17	
7. Cost of steam power per H. P. on above basis if 5 per cent. of the original cost of plant be charged for dividends and $0.75 per H. P. added for general business expenses 15 17 + 3 90 = 18.77; 18 77 + 0.75 =	19.52	
8. Cost of steam power per H. P. per year on above basis if 10 per cent. of the original cost of plant be charged for dividends, and $0.75 per H. P. added for general business expenses. 15.17 + 7.20 = 22.37; 22.37 + .75 =	23.12	

The quantities in the paper above mentioned were augmented here and there so as by judgment to try and approximate the various losses incident to average practice, though insufficiently to show the results of such practice in some locations. The prices herein given are as low as it would be safe to expect with very careful management of a very large plant. The comparatively small difference in result is due to the influence of the constant cost shown in line 4 of the several tables. It forms 26.4 per cent. of the total cost for 20,000 H. P. every hour in the year, Table I.; 34 per cent. for variable power, 20,000 H. P. maximum, 12,760 H. P. average day and night, and rises to 48 per cent. for 20,000 H. P. during 10 hours of the ordinary working days in a year. The cost of coal is respectively 43.4 per cent. 37.3 per cent. and 30.6 per cent. of the total cost for the same three conditions. The fixed charges also increase greatly the cost of water power, as the writer has had occasion to call to the attention of parties engaged in these large hydraulic enterprises.

It should be borne in mind that if water power or power derived from water be sold on a 24 hour basis, but can only be utilized during 10 hours per day, the cost of the water power direct or derived should be compared, not with the cost of steam power on a 24 hour basis in Table I. or II., but with that of steam power on a 10 hour basis in Table III.

It should also be borne in mind that all these estimates provide for fixed expenses, such as interest, insurance, taxes and cost of renewal, and that in comparing the prices above given with the cost of water power, similar fixed expenses should be added to the price of such power, based on the cost to the consumer of installing the water power or the mechanism through which the power is derived. For instance, manufacturers located on the canals of large water power companies necessarily build their own head and tail races and wheel-pits and install the gates, screens, turbines and means of transmission for utilizing the power. This when well done in many locations costs as much as to install a steam plant, so the fixed annual charges for this item alone would be $5.00 to $7.00 per H. P., which together with cost of labor and supplies, must be added to the cost to be paid for the water power in order to compare with the cost of steam power as presented in the tables of the writer.

When power is electrically transmitted, the consumer is generally required to pay for the electric motor, the general means of transmission therefrom and some incidentals. The cost of this work, together with the portion of the building and even of the real estate occupied should be considered in the same way as has been done above, and at least 10 per cent. of such cost, together with actual costs of labor and supplies, added to the tendered price of net power delivered, in order to compare the cost of power obtained in this way with the cost of steam power shown in the various papers of the writer, which are written on the basis that a manufacturer should receive a profit on the money expended in plant as well as that expended in his business. If interest is left out in one case it should be in the other and it is already included in the tables.

The last column of the several tables furnishes a ready means of eliminating either of the items of cost desired. For instance, in Table III., which is on a 10-hour basis, we find in line 4 that the "estimated interest, taxes and cost of renewal" is 48 per cent. of the total cost, which cost to the parties using the power is in such table $15.17 per year, line 6. The cost of steam power per H. P. per year from large units for 10 hours per day, without considering the above items, is therefore only 0.52 x $15.17 = ..$7.89 which is the cost to be compared with the price of power from an external source when the items above referred to are excluded in each case as they are in the popular discussion of the subjects. The similar cost from the estimate in the Transactions of American Institute of Electrical Engineers above referred to is $22.31, less (3.31 + 7.17) = 22.31 — 10.48 = ..$11.83. The difference, $3.94 is due principally to the relative sizes of plants considered in the two cases.

THE E. M. F. OF ALLOYS.

THE December issue of the *Journal* of the Chemical Society contained the paper by Mr. A. P. Laurie on the electromotive force of alloys in a voltaic cell. This interesting paper was suggested to him by a study of Matthiessen's well-known paper in an early number of the *Philosophical Transactions*, 150. The results of the determinations of the electromotive force of 16 of the 19 alloys referred to by Matthiessen are here given, and it is interesting to observe that the latter's conclusions are entirely confirmed, namely, that only one compound exists amongst the 16—the tin-gold alloy. The others were bismuth-tin, bismuth, lead, bismuth-gold, bismuth-silver, gold-silver, antimony-lead-cadmium-zinc, antimony-tin, lead-gold, lead-silver, lead-tin, lead-zinc, lead-cadmium, and cadmium-tin. The method employed in examining these alloys was to prepare small samples from approximately pure metals, and by means of a Thomson quadrant electrometer, to test the E. M. F. in voltaic cells of various construction against that of a standard Daniell.

FOSTORIA, O.—The Citizen's Telephone & Message Co. has been formed; capital $15,000.

COMPOUNDING DYNAMOS FOR ARMATURE REACTION.[1]

BY ELIHU THOMSON.

Considerable attention has recently been drawn to the subject of means for counter-balancing or preventing armature reaction in dynamo-generators or motors The valuable paper of Messrs. H. J. Ryan and Milton F. Thompson, read before the Institute at its meeting on March 20th, called forth considerable discussion as to the actual utility or need of added devices, which undoubtedly render a machine more complex, but which can certainly be made to obliterate armature reaction or overcome its effects. The opinion which seems to prevail amongst engineers is that by taking advantage of the best principles of design, the output of our machines is not limited by armature reaction, but rather by heating, or the capacity to diffuse that heat which is sure to be produced during operation.

The subject itself has been worked upon by the writer as far back as 1879. At first a peculiar disposition of the field coils and pole pieces was selected, unfavorable to armature reactions, and later in a patent applied for by the writer in the year 1885, the series coil of a compound-wound machine was so disposed as to add, under load, a magneto-motive force to the field in the region of armature opposition, and as a consequence to diminish somewhat the magneto-motive force of the field where the reaction of the armature was positive, or assisting.

In the present paper, however, the writer discusses a different type of dynamo, worked upon by him some three or more years ago, in which there is no series winding whatever, though the machine is in effect compounded, or over-compounded at will. The present paper is not intended to advocate the disposition described as a desirable commercial structure, or even as one which will be likely to come into practical use on any scale. The machine is, however, interesting as bringing out forcibly the capability of the armature current to neutralize its own effects in a proper structure and maintain, or even increase, the potential at the brushes under heavy loads. In fact the current in the armature in the type of machine herein treated, is made to react under load to magnetize a portion of the field structure which at no load is neutral or nearly so. The reaction may thus be made to give rise to a magnetic flux sufficient or more than sufficient to compensate for its effect in diminishing the flux of the other or excited portion. The result is accomplished by dividing each field pole into a portion which is left unwound and a portion which is wound and excited in shunt or separately. At no load only, the wound polar portions act to generate the open circuit E. M. F. As the load is put on, the unwound or dead poles become active in consequence of a magnetic flux developed in them by the armature currents themselves, that is, in consequence of the M. M. F. generated by the current in the winding of the armature itself. The disposition of the poles in a bipolar structure would be represented by Fig. 1, where A A are the excited poles, or wound field cores, under the fringe of which commutation is effected, while D D are the "dead" poles or sections of polar surface unenergized at no load. A dotted line a a may pass through the neutral or non-polar portion of the armature iron, threaded by all field lines on one side, while the lines b b may indicate the diameter of commutation on which the brushes rest. In such a structure by choosing the position and spread of the "dead" poles in relation to that of the wound or excited polar portions, and adjusting the E. M. F. of the initial field relatively to the turns on the armature and the speed of driving, the effect of compounding or over-compounding may easily be obtained. The "dead poles" may be made adjustable in position so as to vary the effective M. M. F. of the armature upon them and various changes in relations of the parts are conceivable. In Figs. 2 and 3, an attempt has been made to represent the magnetic flux under no load and under load, respectively.

Fig. 4 is from a photograph of the dynamo constructed in accordance with the principle under discussion. It is multipolar, having four wound poles and four dead poles alternating in position around the armature. The latter is of standard iron projection type, being in fact identical in construction and dimensions with the armatures used about three years ago in regular four-pole dynamos of the marine type of the Thomson-Houston Electric Co.

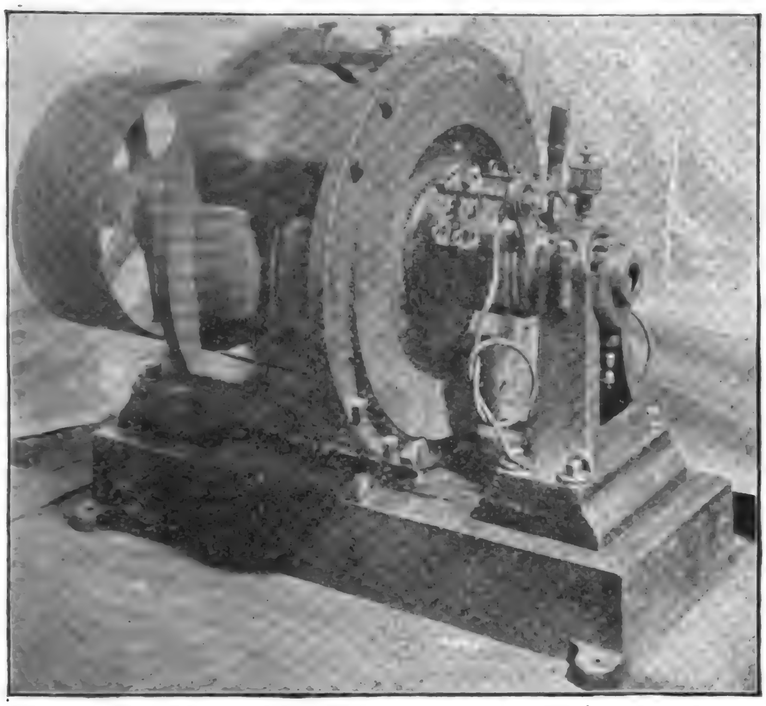


FIG. 4.

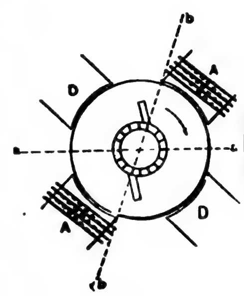

FIG. 1.

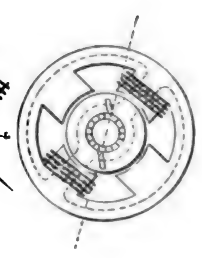

FIG. 2.

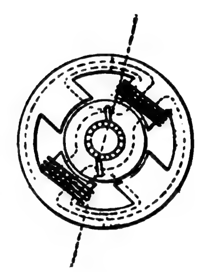

FIG. 3.

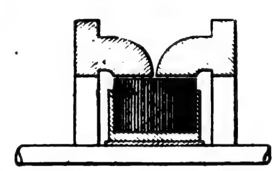

FIG. 5.

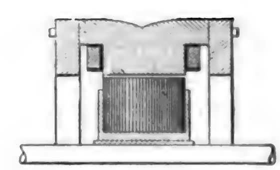

FIG. 6.

The principal data of the armature construction are as follows:

Diameter over all	17	inches
Length (laminations)	8	"
Radial depth of laminations	4	"
No. of projections	87	"
Width of slots	.34	inch.
Depth of slots	.75	"

The armature is series drum-wound and has two conductors in each slot. The commutator has 87 segments. The new field system was constructed of two rings of cast open hearth steel having heavy lugs, four in number, projecting laterally from each ring on one side, and forming the dead poles when assembled in the machine. Fig. 5 is a section of the field in a plane passing through the dead poles and axis of the armature, and Fig. 6 is a similar section through the active wound poles.

The normal current of full load for the armature as constructed and used in the regular multipolar field was 140 amperes, and it was found that as the load was increased steadily during a run, the potential was not only maintained but increased with each increment of load, thus showing an over-compounding effect. This effect was less marked when the initial excitation was weak; as when less than three amperes traversed the field coils. The over-compounding under load was, of course, still more increased when the field coils were connected in shunt to the armature. Thus, at a little over 750 revolutions per minute with an exciting

1. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

current of four amperes, the open circuit volts were 84, rising to 104 when a load of 180 amperes was put on with an increase of the exciting current to 4.8 amperes. It was noticed that on any considerable increase of load being made, the potential rose in some cases as much as 5 or 6 volts above the point at which it would remain; or which it would reach after a short interval. Similarly it was found that the sudden taking off of load caused a temporary fall below the stable voltage under the new or diminished load conditions. This curious effect was traced to the difference of time between that needed to build up or cut down the flux in the dead poles, as compared with that required to cut down or build up the excited poles, which, being wound with wire, were naturally more sluggish under the conditions of use.

Horizontal plottings of the potentials generated in the armature coils under various no loads obtained by the two brush method of Dr. S. P. Thompson, are given, among them two for abnormal or extreme loads. The latter show how completely the wound pole is broken down by armature reaction, and how the unwound poles become the chief working field poles, or rather how the armature winding itself furnishes the field for its own cutting.

The machine described is probably chiefly interesting from a theoretical aspect. Still it shows clearly that so far as the effect of the series field on compound wound machines is concerned, the electrical engineer has other resources at his command giving similar results.

In conclusion it may be stated that tests of the machine used to generate single phase and three phase alternating currents in its armature winding were made by dispensing with the commutator and substituting rings and connections common in such cases. The results indicated a substantially similar effect of compounding, but to a less degree, owing no doubt to the fact that the phase of the electro-motive force generated by the wound pole flux would not coincide with that due to reaction on the dead poles, since the position of the poles with relation to any portion of the moving wire is different at the same instant.

SOME FEATURES OF ALTERNATING CURRENT SYSTEMS.[1]

BY CHAS. PROTEUS STEINMETZ.

The alternating current generator, single phase, or polyphase, when running at synchronism in parallel with other generators, will keep on revolving even if the driving power is removed, and will operate as a "synchronous motor" keeping absolutely in step with the generator. Such synchronous motors are quite extensively used now, especially for large units. They have, however, the disadvantage that they are not self-starting, but have to be brought up to full synchronism before operating as reversed generators. Thus, either external starting devices had to be used or the synchronous motor made what is called "self-starting;" that is, built so as to operate in starting and running below synchronism on a different principle, namely, that of the asynchronous, or induction motor, or that variety of the latter which is called the "reaction motor." Thus, the reversibility of the alternating current generator did not bring the solution of the motor problem.

The solution of the alternating current motor problem had to be expected, either by the adaptation of the continuous current motor to alternating current circuits, or by the discovery of an entirely new principle. The introduction of polyphase systems appeared to give the solution in the polyphase induction motor. This motor necessitates the use of polyphase systems, that is, systems comprising several circuits differing from each other in phase of their E. M. F.'s and currents. Such polyphase systems require the subdivision of the single phase load, as lights, into and between several circuits, and require an approximately equal division to avoid on the one hand overloading of an individual circuit of a generator, while the generator as a whole is not yet fully oaded, and on the other hand to avoid the feature of "unbalancing" noticed in such systems.

However, aside from this difficulty, the experience of the last few years seems to show that the complication of subdividing the circuits in the polyphase system is sufficient in most cases to exclude its use, and thus, comparatively little use has been made of the polyphase system for light and power distribution. It has been different with long-distance transmission of large units, and power distribution, where polyphase systems have established themselves quite extensively.

Hence, the polyphase system did not completely solve the problem of alternating current light and power distribution, and in returning to the single phase system, attempts were made to derive from the single phase system by "splitting of phase," a polyphase system for the operation of motors.

The futility of all attempts to derive a polyphase system from a single phase system, I have previously shown.[2]

It is possible in a single phase system to resolve the E. M. F.'s into components in quadrature with each other or in any other phase relation. The insertion of a reactive coil into a lamp circuit produces two E. M. F.'s approximately in quadrature with each other and differing in phase with the main E. M. F., and by their combination any other phase differences can easily be produced. A condenser in series in the circuit, or an electrolytic cell will give phase displacement of E. M. F. also. But whenever E. M. F.'s displaced in phase are produced in this way, the currents are in phase with each other or are insignificant.

Inversely, differences of phase of current can be produced in the single phase circuit. The current in an open magnetic circuit transformer at open secondary circuit and the current in a transformer under full load, are practically in quadrature. Or still more, if on the same iron core two coils are wound and connected in parallel, the two currents in these coils can by changing the relative number of turns be made to have any phase difference from zero to 180°, but the E. M. F.'s are in phase. All attempts to produce such phase differences in the single phase circuit for the operation of polyphase motors signally failed. While it is possible to operate motors in this way, and this is being done to a certain extent, the current required is far in excess of the torque produced thereby. Such circuits of displaced phase lose their phase displacement as soon as work is required from them. The cause is that phase displacement of current, and phase displacement of E. M. F. cannot be produced simultaneously in a single phase circuit. This is a consequence of the law of conservation of energy.

According to the law of conservation of energy, a change from a single phase to a polyphase circuit or inversely, is possible only by means of apparatus able to store energy, and that the total amount of energy between the mean and maximum value in the single phase circuit must be stored and returned during the time the single phase wave is below the mean. Means to store the energy are, electro-magnetism, electro-static charge, electro-chemical force and mechanical motion. Electro-magnetic and electro static storage are in most cases excluded by low energy efficiency and especially low weight efficiency and inconvenience. Electro chemical storage shows a very low efficiency, and the only efficient way of storing energy appears to be mechanical momentum. This offers a high weight efficiency also, but is for most cases excluded by the complication due to revolving machinery. Excluding storage of energy, we see that the nature of the flow of energy constitutes an essential feature of an alternating current system.

The systems are characterized correctly, not by the existence of one or several phases, but by the existence of one or several waves of energy, or cycles, and for this reason I rather prefer the denotation "polycyclic" for a system of many waves of energy, "monocyclic" for a system with one wave of energy. Hence:

The monocyclic system is an alternating current system of balance factor zero.

The balanced polycyclic system has the balance factor one.

The three phase or quarter phase system with equal load on all branches has the balance factor one.

A three phase system with two branches loaded and one unloaded has the balance factor .5.

A three phase system with one branch loaded and two unloaded has the balance factor zero.

A quarter phase system with one branch loaded and the other unloaded has the balance factor zero.

Still from another point of view, we are driven to recognize the importance of the flow of energy as characteristic in alternating current circuits.

In a continuous current circuit, the direction of transmission, or direction from the generator to the consumer circuit, is in the direction of decreasing voltage.

The direction of transmission in an alternating current circuit is not necessarily the direction of decreasing voltage or decreasing current, but it is the direction of decreasing energy flow. That is, attaching a wattmeter to two points of the line, the wattmeter nearer the generator will always give a higher reading than that farther away from the generator.

The author then discusses as an instance of a polycylic system of a balance factor less than unity, the "Inverted Three-phase System" ("polyphase monocyclic"), and concludes that:

The multiple-circuit generator regulates, or tends to regulate, near the maximum output point for constancy of the balance factor. Thus, the polycyclic machine with balanced circuit regulates for constancy of the flow of energy; the monocyclic machine regulates for a balance factor zero.

This self-regulation takes place by a change of voltage and a shifting of phase of the different generator circuits. It is therefore in general objectionable. A similiar action takes place in multiple circuit motors, induction motors as well as synchronous motors, etc.

It is thus obvious that, with a considerable number of multiple circuit motors in the polycyclic system, even a large inequality in the distribution of the single phase consumer circuits, as lights, between the generator branches, will not unbalance the system. The generator will regulate for constant flow of energy

1. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

2. TRANSACTIONS 1892, vol. ix, p. 91.

and tend to raise the voltage on the lesser loaded, to lower it on the more loaded branch.

The problem of the alternating current motor may be approached from still another side, from the viewpoint of adapting the continuous current motor to alternating current circuits. In similar lines to this, work has been done by Vandepoele, Eickemeyer, Stanley, myself, and others in this country, by Kennedy and others abroad.

The possibility of operating such a motor successfully is based on the feature that the armature coils when reaching the brushes are in a position where no E. M. F. is induced in them, and they can thus be short-circuited by the brushes, in their passage from the one to the other side, without sparking. Such motors, straight, alternating current series motors with laminated field, have been tried but have been a complete failure in all but the smallest sizes, as fan motors, due to their excessive and incurable sparking.

In the continuous current motor the use of brushes and thus of a commutator constitutes the only way to produce the current in the armature. In the alternating current motor the required current in the armature can be produced by induction, by acting upon the armature as secondary in the proper direction by a primary coil, which may directly surround the armature.

To get the field excitation in phase with the main current, the exciting current must be in phase with the main E. M. F. Since, however, in an alternating magnetic circuit, the magnetizing current lags approximately 90° behind the impressed E. M. F., it follows that the E. M. F. impressed upon the field circuit must be 90° ahead of the main E. M. F. Or in other words to produce in such a transformer motor a magnetic field in phase with the induced armature current, but displaced at right angles in space, a supplementary E. M. F. is required approximately 90° displaced from the main or power E. M. F. Being in quadrature with its current, this E. M. F. represents no power and thus need not be supplied by the generator, but may originate from a motor or other multiple circuit apparatus.

We see thus that the alternating current motor requires a supplementary circuit for its operation, the so-called "teaser circuit" of the monocyclic system. One difficulty, however, is met here. Since the movable armature acts as secondary to the stationary primary main circuit, the armature must contain a number of circuits closed upon themselves, but displaced in position from each other so as to form in any position a secondary circuit to the primary.

We have now arrived at the modification assumed by the continuous current motor in its adaptation to alternating current circuits: 1st.—The armature current is induced by a primary energy circuit, instead of being led in by brushes. 2nd.—To keep the field excitation in phase with the armature current, it is derived from an auxiliary circuit of displaced E. M. F. 3rd.—To avoid energy transfer between field exciting circuit and armature, the E. M. F. at the terminals of the field exciting coil is kept approximately equal to the E. M. F. induced in the armature, by the internal reactions of the system. This is the monocyclic motor.

The calculation of such a motor is now simple, and done after the manner of the previous explanation of its action. The torque, and thus the output of the motor are determined by the field magnetization, the armature current, and the angular space displacement between them. The field magnetization is determined by the impressed E. M. F. of the exciting circuit, and the armature current is determined by the equations of the alternating current transformer, as secondary currents induced by the primary energy current. Since no energy transfer should take place between the exciting circuit and the armature, it follows that the counter E. M. F. at the exciting circuit is equal to the E. M. F. induced in the armature, and thus the magnetic flux can be calculated from the latter.

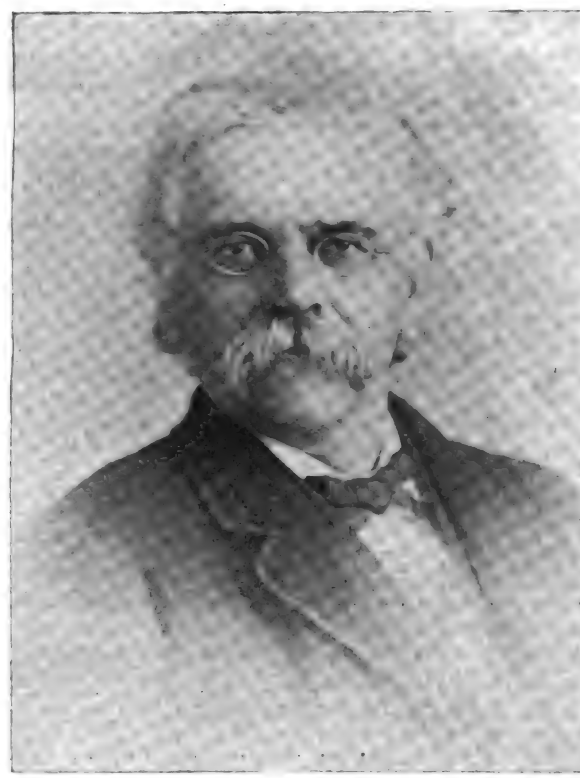
"THE ELECTRICAL ENGINEER" ON ELECTRICITY IN CALIFORNIA AND MEXICO.

During the past six months THE ELECTRICAL ENGINEER has been publishing a series of articles by Mr. George H. Guy, its special correspondent, on the leading electrical features of Mexico, California and the Southwest. These have been read with great pleasure and highly commended, many letters of thanks and praise reaching us with regard to them. One of the most recent of these comments is from Mr. T. T. Crittenden, Consul General of the United States, City of Mexico, who under date of June 24, writes with regard to Mr. Guy's article on the Government Telegraphs of Mexico: "I don't know when I have enjoyed an article more. While I have often used the service and with satisfaction, I freely admit that I knew nothing of its organization under Senor Islas, until I read this singularly interesting article. It is as often true that we have to go away from home to get facts, as to get the ordinary news of society. Mr. Guy has an excellent conception of Mexico. It is a coming country." Mr. Crittend en is a man of much influence and high standing in Mexico, and his commendation carries weight.

OBITUARY.

JOSEPH BARKER STEARNS.

We regret to note the death of Joseph Barker Stearns, inventor of the duplex system of telegraphy, who passed away at Camden, Me., on July 4, at the age of 65. He was born at Weld, Me., on February 28, 1831, learned telegraphy at Newburyport, Mass., and became superintendent of fire alarm telegraphs in Boston in 1855, holding the position until 1869. He afterwards became president of the Franklin Telegraph Company, remaining so until 1871. He had already patented the method of using reversed currents in connection with fire alarm signals; and he now won fame by introducing the first practical system of duplex telegraphy, which was put into use on the Franklin lines between Boston and New York. His duplex was next applied successfully to the Atlantic cables, and his patents were sold to the Western Union Company, and the various cable companies, the sale being the means of bringing him considerable wealth. Mr. Stearns supervised the laying of the cables of the Central and South American Telegraph Co., and during 1882 and 1883 he was vice president of the Mexican and South American Cable Co. Of late years he has spent a well earned leisure at his beautiful home at Camden, Me., on which he lavished time and money. Our portrait is reproduced from Mr. J. B. Taltavall's admirable book: "Telegraphers of To-Day."



JOSEPH BARKER STEARNS.

OPPOSING A "POWER BRIDGE" AT BUFFALO.

United States Engineer Major Ruffner has put his veto on the plans of ambitious Niagara River harnessers, who propose to develop power at Buffalo, by the construction of bridges and piers. Some time ago Major Ruffner wrote to Gov. Morton, advising him to disapprove the Mather bill, because the proposed bridge would, in his opinion, be an obstruction to navigation, hinting that, even if the Governor should approve the bill, the Federal Government would never permit the bridge to be built. Last week Major Ruffner gave expression to his views in a very emphatic manner to one of the inventors. He said that, while the plans were good ones for developing power, he would be compelled to report against allowing such obstructions in the river. Major Ruffner said further: "The present international bridge would never have been built had not the right been obtained just after the war, when things were so unsettled. Another franchise could not be bought for $20,000. What is more, the City of Buffalo could not, under any circumstances, get permission to build another inlet pier.

CONTENTS.

ELECTRIC RAILWAY WORK.

It is natural that the recent successful equipment of the Nantasket Beach road with electrical apparatus by a large steam railroad company, and the successful application of electricity to the hauling of heavy trains through the Baltimore tunnel should attract widespread attention. Indeed, the interest in these two subjects is universal, and there appears to be on the part of the public an expectancy that *now* steam is to give way and the time-honored locomotive be at once relegated to obscurity and oblivion.

We are free to admit our own belief that two such events are very important in marking the arrival at a stage when electricity has so far demonstrated its value that it must enter into the survey and calculations of all steam railroad managers in the future when the question arises of equipping new branch roads or of meeting the competition of the trolley parallel. In this respect, the work at Nantasket Beach has an instructiveness that cannot be surpassed. The change there has been made by a company which, perhaps, more than any other has suffered from the diversion of its local passenger traffic by the trolley, all along its system; and the apparatus is in many respects novel, indicating an attempt to reconcile and combine the best features of the old with the best qualities of the new. How far the blending will answer the purpose elsewhere remains to be seen. The success of the trolley lies largely in its flexibility, in its ease of penetration into remote localities, and we do not think that the old steam roads can be adapted to do this; although it will probably turn out that there is economy over the old steam methods in the adoption of electricity even for the existing tracks.

The work at Baltimore is remarkably interesting, and the huge electric locomotives are confessedly marvels of skill and ingenuity. That they should meet the task put upon them does not surprise us, and that they must be so powerful is a necessity of the case; but as a matter of fact, it seems to us that the real lessons of electric traction lie rather in another direction. There will be a few cases in which such heavy machines and such tractive ability are required; but the field of their use is surely very limited. If steam railroad capitalists and managers welcome electricity, it is not because it adds to the burdens put upon the track, the bridges and the structure of the line generally, but because it offers surcease from the tendencies that of late have asserted themselves in an intolerable manner. What all the roads really need is lighter engines, lighter trains, lighter tracks, lighter investment in line and in rolling stock; and if electricity is simply going to add to the ponderosity of everything, steam railroad men will want none of it.

Of the two sharply contrasted types of electric locomotion thus brought forward within a fortnight, at Nantasket Beach and Baltimore, it does seem, therefore, that the former marks the proper line of development rather than the latter. New conditions of electric current generation and supply may come in, but it will still remain open to question whether it is not better to cultivate the unit system up to the fullest extent rather than strain after the massing system of enormously heavy trains. For the present, at least, the whole success of electricity lies in a study and cultivation of the unit methods, and the dis-

patch of cars at frequent intervals rather than in the running of big locomotives and weighty trains at intervals widely apart.

REVENUE FROM ELECTRIC HEATING.

The Ottawa, Can., Electric Co. has proved itself one of the most progressive lighting companies on this continent. The fact that in a city with a population of but 40,000, it runs 50,000 lights, speaks volumes, and we question whether any other city in the world can approach such figures. But even more interesting is an item in president Ahearn's last report, just presented, showing an income of $421 from heaters. We have not struck this item in any similar balance sheet before, and make its acquaintance with a great deal of pleasure. The expenses, per contra, charged against heaters, are only $12, from which we infer that the service must be quite profitable. It is true that $421 is not a large proportion of the $147,000 received for all services, including incandescents, arcs and motors, but it is a decided beginning and is much larger than the motor account once was with some incandescent companies or the incandescent account with many large arc companies. The Ottawa example of more than 1 lamp per head of population, and of $421 revenue from heaters at an incidental outlay of only $12, is a mighty good one to copy.

THE DEADLY FENDER.

After having clamored with might and main for fenders on the street cars, some of the newspapers in such cities as Brooklyn and Philadelphia are now beginning to kick and complain because the fenders adopted don't work wonders and perform miracles. Just what our friends of the daily press expected, it is rather difficult to ascertain; but judging from their own reports the fender is far more deadly than the trolley. When not deadly, the fenders display remarkable powers of mutilation, and some of the reporters who have been writing articles on: "A Fence with a Fender"; "Braving the Juggernaut"; "An Experience as a Human Pancake"; "Thrilling Bouts with the Trolley Calfcatcher," are now nursing alike their bruises and their wrath. The idea seems to have been that a fender would naturally serve as a gentle hammock, but because it hits hard and is no respecter of persons, it is being unanimously voted a dismal failure by the secular press. Moreover, a great dispute is arising as to what constitutes a fender, and various civic authorities are endeavoring to define what it is and what it is not.

Of course the street railway companies that are expending hard dollars by the thousand to equip their cars look on wellnigh hopelessly, and are still casting around for something that will serve the purpose and satisfy the public. Mr. Rossiter, the new president of the Brooklyn Heights road, finds it his first duty, for example, to fit 2,000 cars with fenders, and he admits that the officers have not yet found exactly what they want. We opine that it will be some time before he succeeds in pleasing the press, let his search be as earnest as it will.

As we have said before and now repeat, good brakes are more necessary to the cars than poor fenders; and we hope ere long to see public opinion intelligently directed to that part of the subject. But with the best of brakes, suicide will remain possible to those who seek to kill themselves on the trolley lines. As one of the Philadelphia papers says, the city itself owes some duties to the citizens other than putting petticoats around the cars, and the necessity of rapid transit must not be subordinated to the unchecked carelessness of stupid foot-passengers. In other words, it approves the Berlin rule that arrests the man who is run over. Speaking of the children, it says, very sensibly:—"There is but one power that can keep children from the streets, and that is the power of the police. There is not a day that scores of children cannot be seen playing on the streets occupied by trolley lines in every part of the city, and until they are forbidden by the police, and arrested when they disobey the order of the city authorities, there will be no safety for children, fenders or no fenders. Children must be protected by a stronger power than themselves, and the only power that can protect them in a great city is the power of the municipality."

The above quotation is a cheering sign that the discussion of trolley car accidents is at the stage when the truth is about to prevail.

JUDGE COXE'S TROLLEY SWITCH DECISION.

So many patents of a fundamental character and far-reaching importance in the electric arts have been declared void by the courts that confidence has been much shaken in the adequacy or value of patent protection. Indeed, one world-renowned inventor has been heard to condemn our whole patent system as a legal method of extorting money from the poor inventor. Nevertheless some recent decisions may serve to give inventors renewed faith in the wisdom and equity of the patent laws; and it is to be noted that the patents covering extensively applied, though secondary, details have been sustained in large part, if not fully, in several instances of late. The most recent case, and one of considerable importance in railway work, is the patent of Van Depoele, No. 424,695 issued April 1, 1890, for "Improvements in Suspended Switches and Traveling Contacts for Electric Railways," which has just been sustained as to its principal points by Judge Coxe, in the suit brought by the Thomson-Houston Electric Co. *vs.* Elmira and Horseheads Railway Co. In his opinion the learned judge pays a glowing tribute to the ability and prescience of Van Depoele as an inventor, and thus brushes aside the arguments of the defense that the arrangement of track-switch, conductor switch, vehicle and contact device by means of which the former switch will act in advance of the latter and the vehicle impart a lateral tendency to the trailing contact by the time it engages with the conductor switch,—involved no invention. On the contrary Judge Coxe, holds that the record shows that Van Depoele's contributions to the art rapidly supplanted the crude and tentative prior structures and have continued in use up to the present time. Of the thirty-five claims embodied in the patent quite a number are so nearly identical in character and scope that the court could find no legal distinction between them but the claims most relied on by the complainants and which are fully sustained are as follows.

2. The combination, with an overhead conductor arranged to receive a traveling underneath contact, of a switching device secured to and depending from the conductor.

4. The combination of a track having switches, an overhead conductor above the track and having switches, and a car on the track provided with a contact carrying arm to engage the conductor at a point in rear of the front wheels of the car.

9. In an electric railway, a switching device for suspended conductors, comprising two or more branching compartments or ways corresponding to the direction of the track, and of the main and branch conductors, and secured to the said suspended conductors, substantially as described.

20. In an electric railway, the combination, with an overhead switch-plate having depending ribs, but open at its extremities, of main and branch conductors extending from its two extremities, respectively, a vehicle, an upwardly-pressed contact-arm attached to the vehicle and tending to move laterally therewith, and a track-switch for the vehicle located so as to operate in advance of the conductor-switch.

It will be noted that some of these claims are very broad and the decision appears to be of far reaching importance in electric railway work.

ELECTRIC TRANSPORTATION DEPARTMENT.

Power House, B. & O. Tunnel Electric Railway, Baltimore.

THE ELECTRIC LOCOMOTIVES AND POWER PLANT OF THE BALTIMORE & OHIO RAILROAD AT BALTIMORE.

I.

The new Belt Line tunnel in Baltimore, on the main line of the Baltimore & Ohio Railroad through the City of Baltimore was undertaken to give this railroad a clear route through to the North. Previous to its completion all trains on the Baltimore & Ohio Railroad running between Baltimore and the North were compelled to take a devious course, and were transferred to a ferry running between Locust Point and Canton. The delay which this water transfer entailed acted for many years to the great disadvantage of the company, as other lines had a clear all rail route through the city. To do away with this delay, the Baltimore & Ohio Railroad secured legislative permission to construct a tunnel under the city, and in September, 1890, work was begun upon the tunnel and line which now runs from Camden Station, in the heart of the city, north, and then east to Bay View Junction, a distance of 7.2 miles.

To construct this road the Belt Line Company was formed, and the actual construction of the tunnel and line was carried out by the Maryland Construction Company, a company formed for that purpose. The tunnel is one of the longest soft earth tunnels ever driven, and runs through the centre of the city, immediately under Howard street, one of Baltimore's principal thoroughfares. The length of the tunnel is 7,389 feet, and the maximum dimensions, after lining, are twenty-seven feet wide by twenty-two feet high. Its cost, ready for the track, is set down at $225 a lineal foot.

II.

With the project for the construction of the tunnel the question of its ventilation became urgent. The disadvantages of its operation by steam locomotives were patent, and it became necessary to find a means of doing away with the smoke and gases either by a scheme of ventilation or the abandonment of steam locomotion in the tunnel. Cable traction was suggested, and other schemes, but all in turn were rejected as inadequate or unsatisfactory. The General Electric Company then offered to undertake the construction of electric locomotives of capacity sufficient to haul the heaviest trains, effect the entire equipment of the system, both for lighting and power, and thus to solve the ventilation problem.

Briefly, the electrical equipment and the work as first outlined was as follows: The locomotives were to operate from Henrietta Street about 1,800 ft. in the open to the portal of the tunnel at Camden Street, and thence to the further end at Mt. Royal Avenue, and for 4,600 ft. further on in the open, or a total distance of about 14,500 ft. The locomotives were to join the rear end of passenger trains going north, at Henrietta Street, and push both cars and locomotives through to the second station, from which point the steam locomotive was to do all the hauling. Freight trains were to be pushed the entire distance. The calculations were to be based on a maximum weight of 500 tons for each passenger train, including the steam locomotives, with a speed of thirty-five miles an hour, and on a maximum weight of freight trains of 1,200 tons at a speed of about fifteen miles an hour, on a grade of 0.8 per cent. The number of trains each way was to be about 100 a day. An electric lighting plant with large incandescent lamps for the tunnel, and arc lights for the stations, was also contemplated.

III.

The power house stands upon the west side of Howard street, east of the tracks leading to the southern portal, and between Henrietta and Montgomery Streets, two blocks south of the Camden station of the Baltimore & Ohio Railway. It is a one story building rising thirty feet from floor to eaves, with walls of brick one foot five inches thick. The roof of slate is supported on iron trusses, and the building is practically fireproof. It is divided into two parts, the engine room occupying the north portion, being separated from the boiler room by a brick wall. The entire length of the building is 322 ft. 1 in. long; the dimensions of the engine room are 223 ft. 10 ins. in length by 67 ft. 9 ins. wide, and of the boiler house 98 ft. 3 in. by 69 ft. wide.

The boiler house is a spacious and lofty room, having twelve boilers (250 H. P.) arranged in six batteries, three of which are placed on each side of the center passage. It is lighted from the roof. The boilers are of the Root water tube type, made by the Abendroth & Root Manufacturing Company. Each boiler is twelve tubes wide and eleven tubes high with six 14½ inch drums

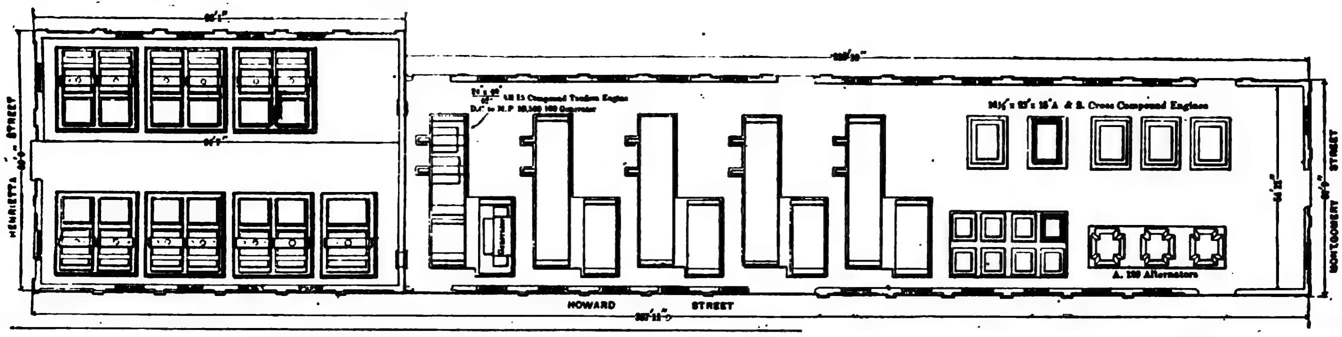
ABENDROTH & ROOT BOILER PLANT, BALTIMORE TUNNEL.

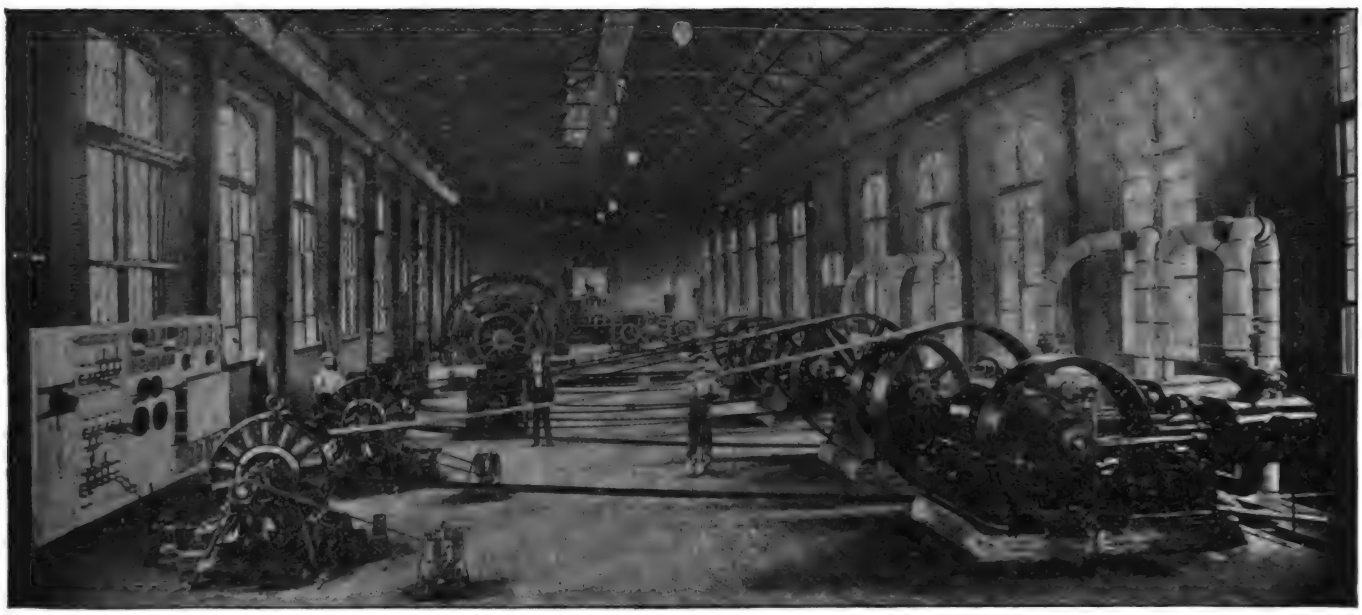
and a thirty inch steam drum. Space is left for an additional boiler on the west side of the room.

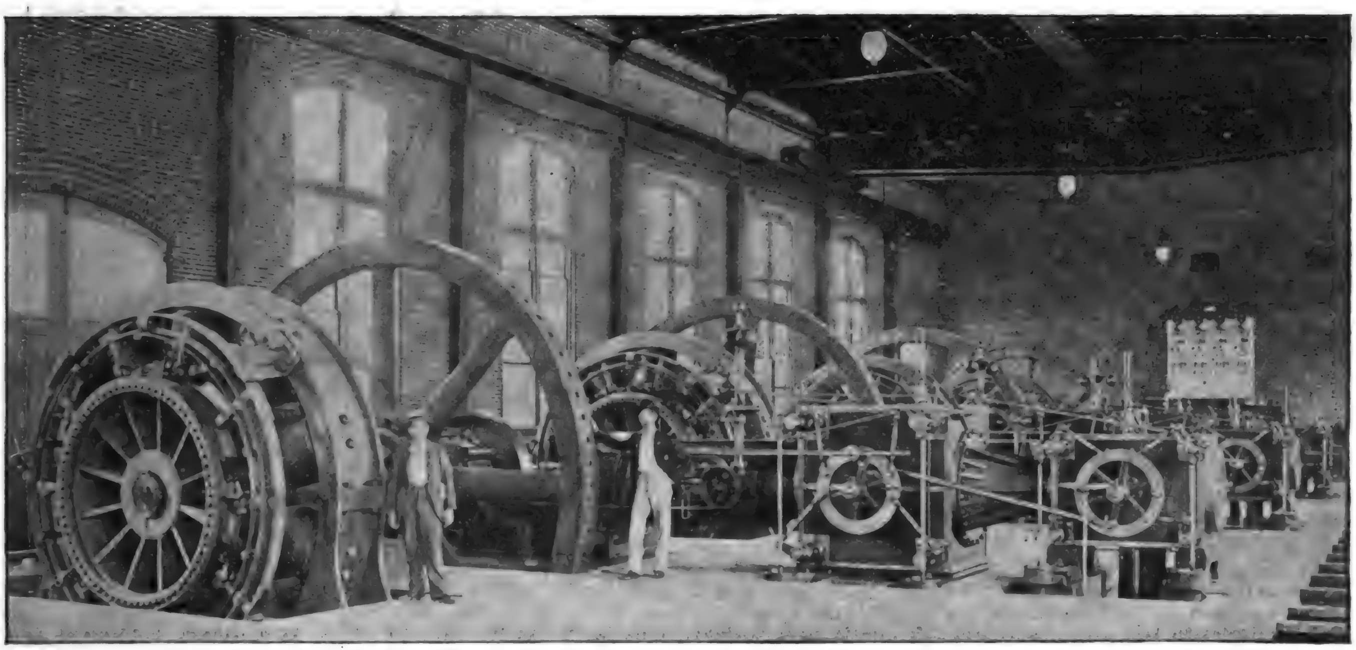
A system of mechanical draft is employed with two fans of the Sturtevant pressure pattern. Each fan is belt driven by a ten horse power vertical engine, set up on the floor of the boiler room, and one is of sufficient capacity to secure the necessary draft.

The boiler room is further equipped with a C. W. Hunt coal crusher and conveyor, which brings the coal to the boiler and carries away the ashes from the ash pits; with Dean duplex feed water pumps, and a 3,000 H. P. Webster feed water heater.

The steam system is duplicate throughout, and was laid out in the Engineering Department of the General Electric Company. Sudden demands for steam likely to be made at times, necessi-







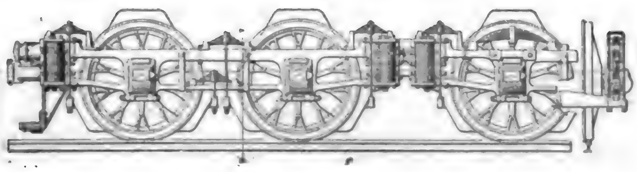
Plan of Steam and Electric Plant and Interior of Engine and Generator Room.

prevents its passage into the engine room system. Each main is provided with a forty-eight inch separator. A novel addition to each boiler is the angle check and stop valve which shuts off automatically from the system any boiler in which a tube has given way, or any part of which has met with an accident.
tated special provision to take care of any water that might be siphoned over from the boilers into the system. The mains from the boilers are, therefore, placed high enough to allow the water to drop into the separators, whence a "Lux" drip system returns all water from this point back into the boilers by gravity, and

A twenty-four inch separator is furnished to each power engine, and one of similar size for each pair of lighting engines. The Holly drip system, described and illustrated in the Engineer of April 24, is used in the engine room, and is connected with the separators at the engines, the valves and expansion joints, wherever there is the slightest pocket in which water could lodge, returning it to the boilers, with only a slight drop in the temperature. The steam piping is protected by Keasbey & Mattison magnesia covering.

The engine room is divided into two sections, one devoted to

the power plant, the other occupied by the lighting generators. In the power section space has been provided for five direct connected engines and generators, and four are now in place. The engines are horizontal, tandem compound Reynolds-Corliss machines, from the shops of E. P. Allis & Company, and have 24 and 40 × 42 in. cylinders. Directly coupled to them are 500 K. W. General Electric multipolar generators, adapted to run with the engine at 110 revolutions per minute. The armatures of these generators are "overhung" on the outer end of the shaft, differing in this respect from the regular practice of railway generators. The armatures are wound for 700 volts potential and are of the iron clad type. i. e., the windings are embedded in slots



TRUCKS, SHOWING METHOD OF COUPLING.

cut into the outer periphery of the laminated armature body. The armatures are of the latest barrel wound type and the machine compounds from 600 volts no load to 700 volts full load.

IV.

From the railway generators the current is brought over cables of 1,000,000 C. M. cross section, to a switchboard of white marble, erected on a platform raised at the south end of the engine room. This switchboard consists of four standard "K" generator panels, each equipped with all the necessary instruments for controlling and measuring the current from one generator. The machines are protected from accident arising from short circuit by automatic circuit breakers, one of which is fixed to the upper part of each panel.

The northern section of the engine room contains the lighting plant, consisting of eight fifty-light Thomson-Houston arc generators, and two alternators for the incandescent lamp service in the tunnel. The arc light machines are belted to two cross compound Armington & Sims 250 H. P. engines, $16\frac{1}{2} \times 28 \times 19$ ins. Two other engines, of similar make and capacity, drive the two alternators, and space has been left for an additional engine and alternator. Each alternating generator has a capacity of 2,000 sixteen candle power lamps, and as the tunnel is lighted by 1,000 thirty-two candle power lamps, one alternator will suffice for the present illumination of the tunnel. Facing the lighting plant, on the east side of the room, is the lighting switchboard, also of polished white marble. It consists of one standard, twenty circuit, arc lamp plug board to which only sixteen circuits are at present connected; three alternating generator panels, one of which is left blank, and one feeder panel. The arc lamps used in the illumination of the power house are of the Thomson 1893 type. In addition, it is lighted by clusters of three incandescent lamps each, fixed to the walls. The approaches and stations are lighted by Thomson-Houston standard arc lamps.

From the positive bus on the railway switchboard, eight cables of stranded copper, each of 500,000 C. M. cross section, or a total cross section of 4,000,000 C. M., pass to the overhead structure immediately outside the power house, where connection is made to three feeder cables, of 1,000,000 C. M. cross section each, and to the overhead conductor itself, which has an equivalent of 1,000,000 C. M. cross section. The negative bus is similarly connected to the rails, which are double bonded with No. 0000 wire, and also to the return cables laid in a wooden box between the tracks. Perfect contact between bonds and web is obtained by using a hollow rivet on each end of each bond and expanding it, when inserted in the rail by means of a conical steel pin.

V.

The distance over which the electrical locomotives will operate is about 15,000 ft., passing through two tunnels, 7,339 ft. and 265 ft. long, respectively, and over 7,396 ft. of track in the open from Hamburg Street to Huntington Avenue. Three tracks are laid into the southern portal, two tracks passing through the tunnel, four tracks from the northern portal, through the Mt. Royal Avenue arch, and two tracks as far as Huntington Avenue, where a siding is provided for the electrical locomotives. There is a steady grade of .8 per cent. from the southern through to the northern portal, and the lines in the open have two equated curves of 10 degs., with a steady gradient of $1\frac{1}{2}$ per cent. At the power house end of the line the locomotives run on a siding at the beginning of the long open cut running down to the southern portal.

The operation of the freight trains will begin at the main tracks south of the Camden station, where they will be switched into the cut. The electric locomotive will then couple on behind, without stopping the train, and push it through as far as the Mt. Royal Avenue portal, a distance of 8,146 ft., the steam locomotive doing no work. After passing out of the tunnel, both steam and electric locomotives pull and push together up the heavier grade as far as Huntington Avenue, the average speed over the entire distance being about fifteen miles an hour. At Huntington Avenue the electric locomotive will uncouple and run into its siding.

The plan of pushing the passenger trains through the tunnels has been abandoned, in view of the possible results if one of the cars or the steam locomotive should leave the track, in front of the heavy electric locomotive traveling at thirty miles an hour. The passenger trains will, therefore, be pulled through from the Lombard Street station near the south end of the tunnel to the Bolton Street station at the north end.

VI.

The 96-ton locomotive, built by the General Electric Co., has the following dimensions and capacity :

Number of trucks	2
Number of motors	4—2 to each truck.
Weight on driving wheels	192,000 lbs. (96 tons).
Number of driving wheels	8
Drawbar pull	42 000 lbs.
Starting drawbar pull	60,000 lbs.
Gauge	4 ft. 8½ ins.
Diameter of drivers	62 ins. outside of tires.
Length over all	35 ft.
Height to top of cab	14 ft. 3 ins.
Wheel base of each truck	6 ft. 10 ins.
Extreme width	9 ft. 6½ ins.
Diameter of sleeve bearings	13 ins.

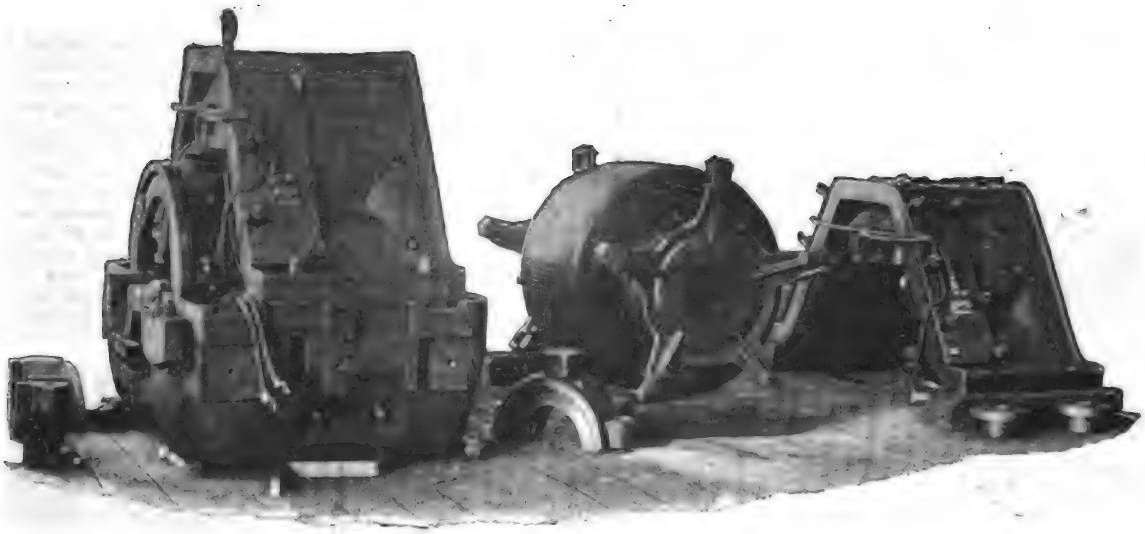
The driving gear consists of a cast steel spider shrunk on and keyed to a cast steel driving sleeve, having a tensile strength of

END VIEW OF ELECTRIC LOCOMOTIVE.

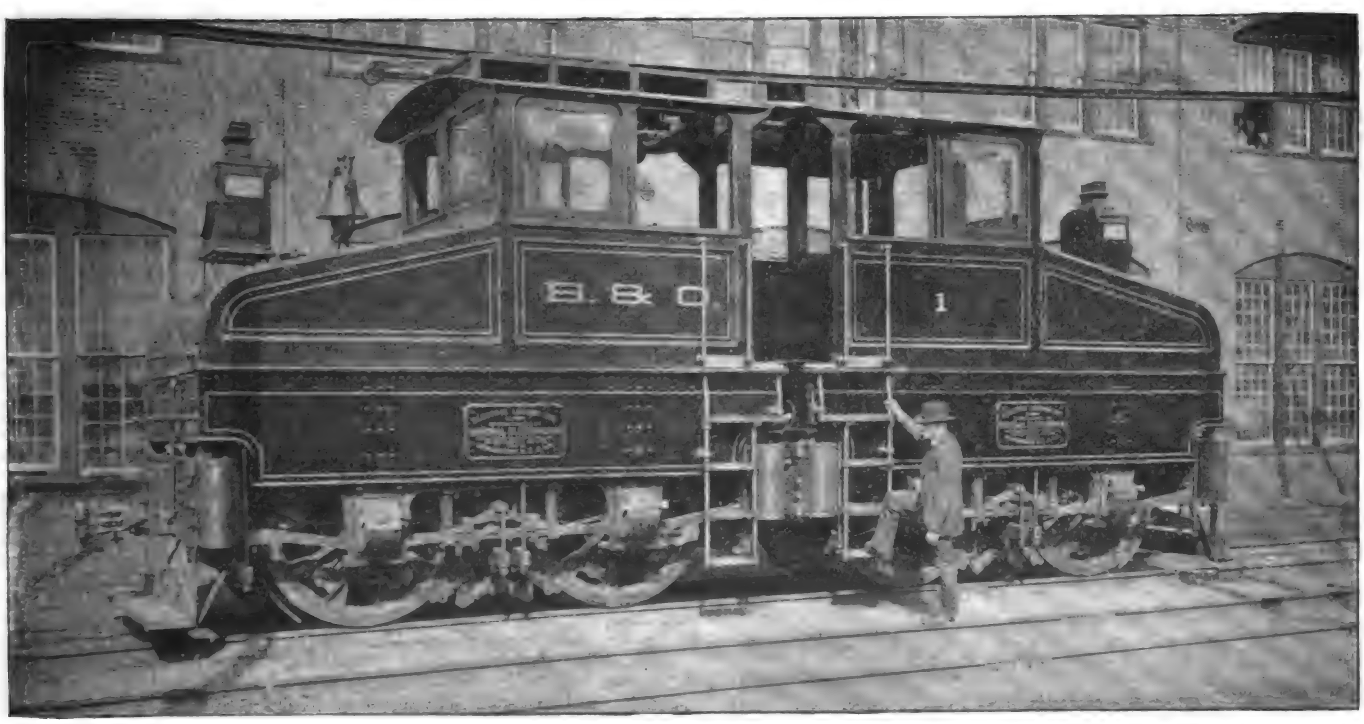
not less than 80,000 lbs. Each arm of the spider is provided with a double rubber cushion, with a chilled cast iron wearing cap, the cushion being forced into the arms of the spider and the cap. The eight driving wheels are of cast steel pressed and keyed to the axles, and have tires, three inches thick at centers of tread shrunk onto the wheel centers. The driving axles are of special open hearth steel. The journal bearings are outside the driving wheels and allow of easy access to all parts of the truck frame and driving box. In the design of this are embodied the good features of the steam locomotive driving box and passenger car box.

The two opposite side frames of each truck rest upon four wheels, each consisting of one piece of hammered wrought iron, $3\frac{1}{2}$ ins. thick, to which the frame jaws are welded, and protected from wear by cast iron shoes, and are connected together at the ends by heavy forged iron plates, with oak bumper beams between them.

The drawheads are of the Janney type, similar to those used on the Baltimore & Ohio passenger locomotive tenders, and are made of cast steel with wrought iron knuckles. In coupling with freight trains the ordinary link and pin will suffice; but for passenger service the Janney couplers, with which each locomotive is provided, are used. The front and back of the locomotive is provided with safety chains, and in addition to the regular couplings, between the trucks, safety links are used. The buffers between the motors act as spacers for, and fit between plane surfaces in, the field magnets. These spacers have a complete freedom of movement which allows the field magnets to rotate when the motor is in action. These buffers and spacers are so placed as to permit the interchange and reversal of the positions of the field magnet without requiring change in the position of the spacers. The motors are supported on carriers bolted to the field magnets, and rest in adjustable hangers carried on half elliptical springs placed on top of the frame and bumpers. The frames thus carry the motors by carriers and springs, and this load is carried in turn by rubber blocks in a cast iron casing.



The Motor Unassembled.



Side View of Electric Locomotive.

The cab is of sheet steel and the arrangement is such that all the commutators are visible to the motormen.

The locomotive is fitted with sand boxes, and Westinghouse automatic driver and train brakes are provided for all wheels, bearing upon the flanges and outside tread only. A brass signal gong 8 inches in diameter is placed in the cab to be rung from either end of the locomotive. The headlights, of which there are two, are placed on the top of the shields at each end, and are twenty-three inch lights of Baltimore & Ohio standard pattern. One shield also carries a Baltimore & Ohio standard whistle, blown by compressed air. The other shield carries a standard bell, operated by an automatic air pressure bell ringer. The locomotive is painted with the standard color and design of the Baltimore & Ohio Company.

VII.

The gearless motors are four in number, two to each truck, flexibly supported and transmitting their power to the wheels through the flexible connections described above. They are of pyramidal shape, are the largest railway motors in the world and, while ponderous in appearance, are by no means so bulky as might be expected from the heavy work they have to perform. Each has six poles and six sets of carbon brushes, the brushes being connected to a yoke revolving through 360 degrees to facilitate accessibility to them. It is possible to remove four

brushes without disabling the motor. The field spools are encased in sheet iron cases and fitted over the pole pieces bolted to the field frame. The armatures are built of sheet iron laminations, and are series drum wound iron clad. The armature, with the commutator, is mounted upon and keyed to the hollow sleeve which is carried on the journals on the truck frame. The inside diameter of the sleeve is about two and a half inches larger than the axle. The entire motor is practically fireproof. Each motor is rated at 360 H. P. and takes a normal current of 900 amperes.

When normally placed, the motor rests in a position concen-

OVERHEAD WORK IN CUT.

tric to the axle, the clearance between the axle and the sleeve allowing of a flexible support. The interposition of the rubber cushions, through which the torque of the armature is transmitted to the driving wheels allows the armature to run eccentric to the axle when the motor departs from its normal position on account of any unevenness in the track. The motor is designed to allow of ready removal of the field frame for inspection or repair.

A test of the first completed truck, representing one-half of the locomotive, was made upon the tracks at the Schenectady shops of the General Electric Company. In order to obtain the necessary load, a heavy six-wheel engine was made use of and the electric locomotive truck coupled to it. The machines were then sent in opposite directions and tugged at the connecting coupling as in a tug-of-war. The electric locomotive had a slight advantage over the steam engine in weight on the driving wheels, and pulled it up and down the track with apparent ease. For the same weight upon the drivers it was shown that the electric locomotive starts a greater load than the steam locomotive. The pull being constant throughout the entire revolution of the wheel, the difficulty of variation of pull with the crank angle, as in the steam

INTERIOR OF TUNNEL.

locomotive, is eliminated. The test also proved the driving mechanism and armature couplings amply strong to transmit the torque of the armature to the axle. The controlling devices, etc., occupy the interior of the cab. The controller is erected in one half of the cab, and is of the series parallel type. The reversing lever projects through the upper plate of the controller cover. The resistances are placed around the frame beneath the floor of the cab. The locomotive is equipped with a 1,200 to 3,500 automatic circuit breaker and one 2,000 ampere magnetic cut-out, a 5,000 ampere illuminated dial Weston ammeter and one illuminated dial Weston voltmeter. The compressed air for the whistle and brakes is supplied by an oscillating cylinder electric air pump, the air tanks being placed at each end of the complete locomotive. In the cab are incandescent lights.

VIII.

Contact with the overhead conductor is effected by means of a sliding shuttle-like shoe of brass, which is fixed to a flexible support fastened to the top of the cab. This "trolley" support is diamond shaped and compressible, contracting and expanding as the height demands, and is arranged to lean on one side or the other as the locomotive runs on one side or the other of the overhead conductor. It is, however, rigid in so far as movement forward or backward over the locomotive is concerned. The current is brought to the locomotive by means of cables connected to the shoe and fastened to the "trolley" support.

The conductor is simply a reversed iron conduit or trough erected overhead on trusses in the open, and in the tunnel attached to the crown of the arch. In the open the conductor is directly over the centre of the track; in the tunnel over the cen-

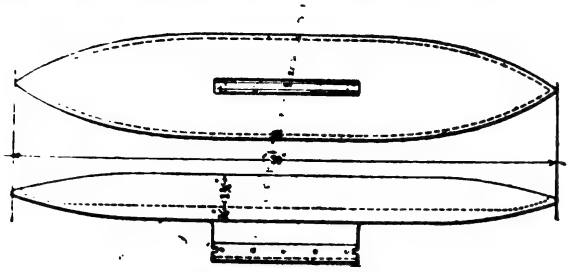
THE ENTRANCE TO THE TUNNEL.

tre line of the space between the tracks It extends from Henrietta Street on the south to Huntington Avenue on the north, a distance of 15,000 ft. The conductor consists of two 8 in. iron Z bars 3/8 in. thick, riveted to a cover plate 1/4 in. thick and 11 3/8 ins. wide, and is constructed in sections 30 ft. long. It weighs about 80 lbs. per foot. At intervals of 15 ft. inside the tunnel there are suspended from the arch, transverse frames, consisting of two 8 in. channels, held together by plates 4 ins. wide, and holding four castings into which are fitted conical porcelain insulators. In the masonry of the tunnel are fitted the bolts necessary to support these frames. They are 2 ft. 6 ins. long, have split ends, and extend 12 ins. into the masonry. The bolts pass downward through the outside pair of insulators. The bolts attaching the conductors to the channel frames pass through the inside pair of insulators and support an iron stirrup in which the conductor hangs; this method affords a double insulation. The height of the conductors above the level of the top of the rails is 17 ft. 6 ins. in the tunnel, and they are fixed a little on each side of the centre line. This plan was adopted to avoid the risk of the conductors striking brakemen who might be standing on the top of passing freight cars. An additional precaution is provided in the shape of continuous wooden shields fastened to the iron stirrup which supports the conductors.

IX.

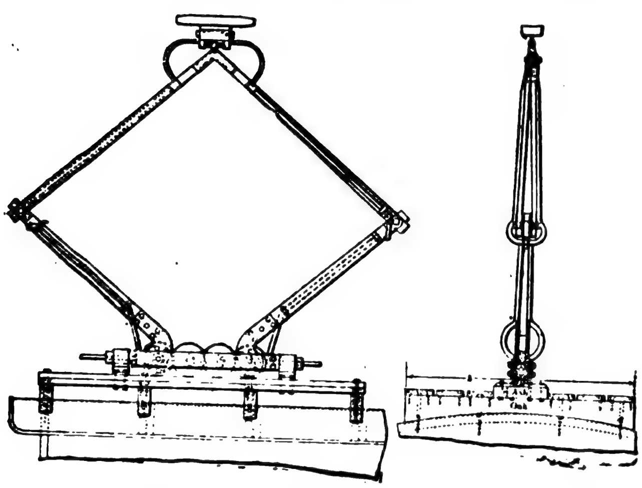
Outside the tunnel the height of the conductors above the rails is increased to twenty-two feet. The supporting structure in the

open consists of longitudinal catenaries of two chains of iron rods, having a span of 150 ft. suspended from transverse trusses, supported by columns of latticed steel channels erected on either side of the double track. The catenaries pass over the top chord of the



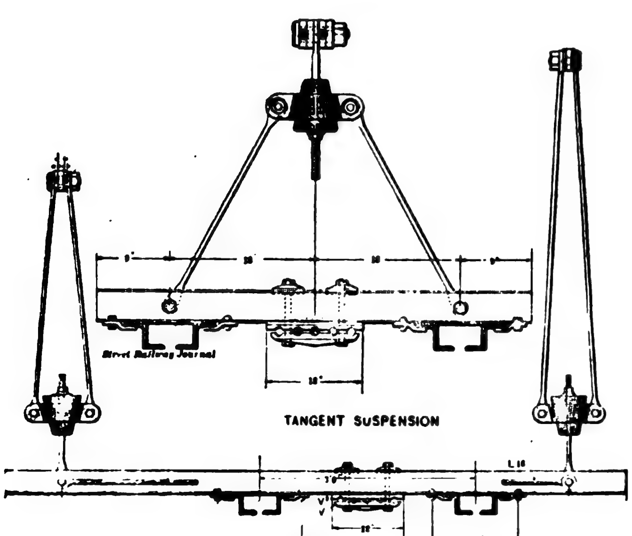
SHOE FOR TROLLEY.

transverse trusses and are fastened to a yellow pine timber post, acting as an insulation set therein. From the joints in the catenaries vertical rods are dropped at intervals of fifteen feet to support the electrical conductors. The vertical rods are attached to



SIDE AND END VIEWS OF TROLLEY.

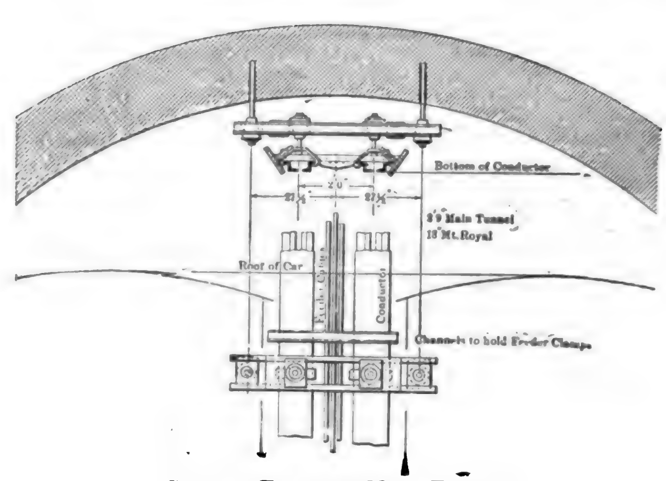
a casting holding a porcelain insulator, and through this a short bolt passes up to the joint in the catenary. The double insulation is secured by this vitrified porcelain insulator and the timber post, passing vertically through the transverse girder. A hood of galvanized iron is fixed to the top of the timber post. At the ends of the line an anchor pier receives the ends of the conductors. The trusses vary in length from 30 ft. to 62 ft., the latter being required to span five tracks. All the iron work was made by the Maryland Steel Company.



SECTION OF CURVE SUSPENSION.

Upon the straight track the conductors are suspended from single catenaries, while upon the curves a double catenary is employed, and the conical insulator is inverted and supported in a casting bolted to the two vertical rods which drop from the catenaries. The vertical rods support a channel frame to which are bolted the conductors and the feeder cleats or clamps. Each joint of the conductor is bonded with a Chicago bond of two No. 0000 wires. The feeder cables are of bare stranded copper of sixty-one strands each of 1,000,000 C. M. cross section. These are supported in iron cleats fastened to channel frames riveted to the overhead conductors at points near to the heavier channels to which the conductors are suspended.

The lead covered primaries for the tunnel lighting plant are



SECTION THROUGH MAIN TUNNEL.

carried on posts set on the side of the cut, to the southern portal, where they drop to the tunnel and are carried upon porcelain knobs fastened to wooden blocks bolted to the masonry. At the points of support the cables are armored with wire to prevent abrasion. The secondaries are carried in cleats, also fastened to wooden blocks, similarly attached, and placed on either side of the tunnel about eight feet from the ground and fifteen feet apart. They are, however, staggered, and thus occur alternately at every seven and a-half feet throughout the tunnel. Each block carries a lamp at its lower end, and is there cut out so that the lamp socket may be protected from moisture and dripping water from the tunnel walls. The lamps used are thirty-two candle power, fifty-two volt Edison standard incandescent lamps.

THE ELECTRIC LOCOMOTIVE A COMING NECESSITY.

BY ROBERT S. BALL.

In a recent article which appeared in THE ELECTRICAL ENGINEER, Mr. H. G. Prout seemed to be of the opinion that the time is still remote when electricity will justly claim a share as an agent of motive power on our interurban lines. His reasons were, that the first cost of an electric road would be too far in excess of its steam competitor to justify its adoption, and furthermore that an electric locomotive had not yet been built that could outrun the steam engine. Both of these statements are certainly true, but let us hope that in the near future an electric locomotive will be designed and built which will outclass its rival in speed. This I feel sure is not as difficult a problem as some would lead us to suppose, and if we are to make engines of either type to pull trains at a higher speed than at present I contend that the electric locomotive will be selected for that duty.

As long as we accept present conditions and hope for nothing better in the way of increased speed of travel between our cities, then undoubtedly the electric locomotive for such service, will never be put to the the test. If however, the future demands quicker train service and higher rates are fixed to offset the interest on the first cost of an electric system, it will not be long before engineers will overcome the problems in designing an electric engine to meet the requirements.

The steam locomotive has, as far as speed is concerned, almost, if not quite, reached its limit. Better results in economy of fuel and efficiency as a converter of thermal into mechanical energy can be expected in the future by compounding, steam jacketing, etc., but with some exceptions, notably that of the famous No. 999, we cannot hope for a decided advance, as far as our present knowledge leads us, in the direction of higher speeds.

Apart from the mechanical difficulties involved in building a locomotive for higher speeds than those we are accustomed to, and in making a more cumbrous machine than that we now have, the effect of such an engine on our track and road bed would alone compel us to look for some other means to gain our ends,

Perfect counter-balancing of our locomotive reciprocating parts has not yet been attained, and each mile we add to the speed brings with it an increased trouble from this source. The electric locomotive, on the other hand, is free from the above serious fault. Instead of heavy side rods, connections, and reciprocating parts all adding to reduce the life of both engine and track, we have a perfectly balanced, comparatively simple and easily controlled machine, and whether we use direct or reduction motors the number of parts subjected to wear and tear is far less in this type of engine.

The problem really resolves itself into one of commercial expediency. If we are content with our present transit facilities let us lay aside the electric locomotive and continue to use our old type, but if commerce and business demand a quicker inter-urban train service we must cut loose from steam which has served us so long, and resort to electricity to supply our wants. The demand will soon produce the necessary locomotive, and if the time which is now spent in trying to improve our steam locomotives were directed into the new channel all the apparent mechanical difficulties would vanish. Let us hope this day is not far distant.

"HAVING FUN WITH THE MOTORMAN."

The Thompsonville, Conn., *Press* records the following incident:—A motorman on the electric road had a terrible experience the other night. He was rushing his car along at a high rate of speed through a lonely part of the road when he saw the form of a man lying across the rails. He put on the brake and switched off the lever that regulates the current, but it was too late. There was a jar and the body was under the wheels. The passengers knew an accident had occurred and the women shrieked. When the car stopped the motorman sank down in his box overcome by the shock. The conductor ran back and found that the corpse was a dummy that some practical joker had placed on the rails. The conductor had to run the car the rest of the way to Windsor.

INSURANCE WAR ON THE TROLLEY IN CHICAGO.

By a practically unanimous voice the underwriters of Chicago have adopted resolutions protesting against the introduction of the trolley system in the business centre, denouncing it as a menace to life and property and declaring in favor of an increased rate of insurance upon all property on downtown streets that may be used for such a system in the future. This action of the insurance men is said to be the beginning of a determined fight against any further encroachment upon the business district by the trolley. The aid of the Mayor and Common Council is to be solicited in the warfare against the overhead wires.

TROLLEY COMPETITION TELLS AROUND PITTSBURGH.

The effects of the trolley car competition between Pittsburgh and Carnegie and intermediate points is already noticeable on Panhandle suburban trains. The electric cars are being well patronized, and this fact is alone sufficient proof that the steam road must be losing patronage. The Panhandle trainmen admit a considerable falling off in traffic from Idlewood into the city, and the decline is particularly noticeable at Carnegie, where the electric cars run past the doors of hundreds of people who formerly had to walk to the railway station when they desired to take a trip to the city.

A BIG DETROIT RAILWAY MORTGAGE.

The Citizens' Railroad Company of Detroit has filed a $7,000,000 blanket mortgage covering its property to the New York Security and Investment Company. It is a consolidated mortgage and is made to cover all the company's indebtedness and for the continuance of its work of equipping the lines with electricity.

CHICAGO AND NORTHERN PACIFIC TO "ELECTRIFY."

The Chicago & Northern Pacific has decided to equip Chicago suburban service of the Co.'s lines with electricity. If permits which the Chicago & Northern Pacific desire are granted promptly change of motive power will be made on its suburban branches within 90 days.

TROLLEY PARTIES IN PHILADELPHIA.

The Philadelphia local papers say that the trolley parties are reviving and promise to put all former attempts in this line in the shade. There is a noticeable absence of noise in those that have been perpetrated so far this summer. Instead of the objectionable blowing of horns and the ringing of bells there is a great singing of alleged popular songs, which is, perhaps, even a worse offense, although not a punishable one. The cars are decorated with small American flags and bunting, and illuminated with small electric lights, that are scattered all around the cars, both inside and out. The brightness of the lights is a means of attracting crowds of people, who cheer the trolleyites to the echo. Judging from present indications the trolley parties promise to be more the go than last year, and the "trolleyosis wards" in the hospitals for the incurably insane will probably be taxed to their utmost extent.

LETTERS TO THE EDITOR.

THE MERIT OF THE "ENGINEER" DATA SHEETS.

Permit me as an electrician to tender my thanks to THE ELECTRICAL ENGINEER for the new work which it has just begun under the name of data sheets,—which, as you infer, will certainly be very highly appreciated by the profession.

I have spent much time and attention for a considerable period past in the vain attempt to procure an ideal pocket-book,—one which should contain exactly what I want, only what I want, and so arranged that I should be able to turn to it quickly when wanted. Any one else who may have made a similar search has no doubt met with a similar result. Of all the mechanical, electrical and general engineering pocket-books extant—and their name is legion—I have found but two or three which even, I will not say approximate my ideal, but can be of any practical assistance worth mentioning outside of tables of logarithms and trigonometrics.

The fact is, that it would be unreasonable to expect such a want to be filled through the medium of any bound volume, which to obtain sufficient sales to pay for itself must necessarily contain a sufficient quantity and variety of matter to satisfy any one of the vast number of occupations included under and connected with the general titles of engineer and electrician. A skilled engineer doesn't want his notes cumbered with an exposition of Ohm's law and examples in arithmetic, while conversely the "practical man" has no use whatever for the calculus and many formulae indispensable to others. Again, storage batteries, alternating currents and telegraphy have little in common, yet men engaged in each of these departments have to carry around with them full accounts of them all, or else only such vague and general data in his own line as can be of little assistance to him.

Nevertheless I would not entirely exonerate the authors from the charge of not doing as well as they might under the circumstances. In the first place many pages are often filled with matter whose only excuse for insertion appears to be to fill up space and give purchasers the worth of their money. Probably about one-half of what appears in the average engineer's pocket-book ought to be relegated to the book-shelf, instead of the pocket. More frequently what one does want is *not* to be found, partly because it has been overlooked, by the author, partly because the book is necessarily not up to date. But waiving these objections, I find the very serious faults with *all* pocket-books into which I have yet looked, that they are not properly, or sufficiently, indexed. Information which I *know* to be in a book I am often unable to locate in time of necessity, simply because I cannot think of it under the same heading, general or particular, as the author did. If I should set out to compile a pocket-book, and should profit by my experience, I believe the index would occupy at least ten per cent. of it.

As an illustration of the above remarks, I may say that, in the book I am at present using, not more than 75 of the 685 printed pages (and those nearly all tables) have ever been found useful; the most useful part of the book is that which has been added in pen and ink and cuttings from different sources pasted in, so that the book would serve nearly the same purpose if the original matter were all removed except a few tables.

The method adopted by THE ELECTRICAL ENGINEER is of sufficient flexibility to overcome all these difficulties, and it is to be hoped that it will succeed in overcoming them. I have not yet seen the covers for these sheets, but I trust they are no larger than will conveniently hold 100 to 150 leaves, for this will certainly be all that the average electrician will wish to carry in his pocket. If more sheets are necessary they may be kept in a second cover on the bookshelf.

THE ELECTRICAL ENGINEER deserves much credit for this new effort to please its patrons, and in the interests of all it is to be hoped that it will meet with deserved success. There is only one objection to be raised, namely, that we cannot have our golden eggs all at once, but perhaps we may hope for one every week, if not like those of the historic goose, every day.

GEORGE W. COLLES, JR.

HOBOKEN, N. J., July 2, 1895.

"IT IS WORTH THE MONEY."

A reader in Central Pennsylvania writes: "I am very well pleased with the ENGINEER and hope you will succeed in getting all interested parties to subscribe. It is worth the money."

TELEPHONY.

THE ELECTRIC MESSENGER CO.'S TELEPHONE PLANS FOR PITTSBURGH.

PITTSBURGH is to have an independent telephone system and cheaper rates. These will be furnished by the Electric Messenger Company of Pittsburgh, which secured its charter October 15, 1894, to operate telephone and telegraph lines and exchanges. The capital stock then was $25,000, of which $2,500 was paid in. This amount has since been increased to $500,000 by the board of directors, which includes J. N. Pew, president of the Peoples Natural Gas company, who is president; W. S. Miller, solicitor for the gas company; Joseph T. Colvin, formerly president of the National Bank of Commerce, secretary; Representative William T. Marshall and Samuel G. Pew. Theodore Johnson, treasurer of the Peoples Natural Gas company, is treasurer, and the other stockholders are Thomas Bigelow, R. S. Duffield, superintendent of the Peoples Natural Gas company, and E. O. Emerson, of Titusville. Many other local capitalists have interested themselves in the new company, and Congressman Thomas L. Johnson, of Ohio, has expressed a desire to become financially interested. He, it is understood, with H. H. Weaver, of the Cambria Iron company, will connect the already complete exchange in Johnstown with the lines of the new concern. Capital from the East has also been largely drawn upon to make the company fully equipped to battle with its great rival, the Bell company.

It is the purpose of the company to erect exchanges in, and run its lines through, the counties of Adams, Allegheny, Armstrong, Beaver, Bedford, Bucks, Butler, Cambria, Crawford, Chester, Cumberland, Center, Clearfield, Clarion, Delaware, Dauphin, Erie, Fayette, Franklin, Greene, Huntingdon, Indiana, Juniata, Lancaster, Lebanon, Montgomery, Mifflin, Mercer, Philadelphia, Perry, Schuylkill, Venango, Washington, Westmoreland and York. By taking in these counties almost every city and town in the State of any importance will be touched. An ordinance has already passed the Pittsburgh Councils granting the right to lay lines and erect poles in Pittsburgh, and a similar ordinance is now pending in Allegheny Councils for rights of way on the North side.

Plans are being prepared by Engineer F. H. Carlson, of the Peoples Natural Gas Company, for the conduits in which the lines in the downtown district will be laid, and it is expected active work will start in the construction of these during July. Work in the city, according to ordinances, will have to stop on November 15, so that the line cannot be completed until next year. At the same time work on the main line to Philadelphia will be begun and continued throughout the winter. Charters have also been secured in New York and New Jersey, and the company expects no trouble in crossing Jersey and reaching the metropolis. It is expected the line East will be completed as far as Greensburg by the time the Pittsburg exchange is opened for business. The line will parallel the Pennsylvania railroad, with branch lines to all towns near it. A similar line is to be run parallel to the Allegheny Valley railroad, reaching the rich and populous towns in the Allegheny valley to Buffalo.

Charters have also been secured in Ohio, Indiana and Illinois, and a line will be run to Chicago by way of Cleveland and the large lake cities. It is the intention to begin work on this line almost at the same time the main Eastern artery is started. It is expected all the large cities in these States will be equipped within two years. A branch wire will be run down to Wheeling, including other Ohio valley towns, the company having rights in Western Virginia.

OFFICIAL PRICE OF BELL STOCK.

The Massachusetts commissioner of corporations has fixed the price at which the 10,000 shares American Bell Telephone stock shall be offered to shareholders at 194, and gossip says the market price gravitated to that level. This is equivalent to 198½ dividends on and is a shade under the expected price.

BELL TELEPHONES IN USE.

The gross output of Bell telephones in the month ending June 20 was 16,753, a gain of 7,627; returned, 7,435, an increase of 1,109; net gain in output, 6,518. Since Dec. 20 the net gain in output has been 56,245. There are 685,882 telephones in use.

THE STANDARD TELEPHONE & ELECTRIC CO.

The Standard Telephone & Electric Co., Madison, Wis., makers of the Mildé telephone, in the past ten days have closed contracts at Ishpeming, Mich., with the Marquette County Telephone Co., for 500 instruments; The Western Electric Telephone Co., of Britt, Iowa, for 10,000 instruments; also closed contract with the New York State Reformatory for full plant; with the Pecos Mining Co., Eddy, New Mexico, for a full supply of instruments; and have received orders from Mayfield, Ky., Scottdale, Pa., Peoria, Ill., Hagerstown, Md., Minneapolis, Minn., Rochester, N. Y., Butler, Ohio, Portland, Ore., San Francisco, Cal., and are receiving telegrams and orders daily from all parts of the Union.

TELEPHONE NOTES.

PRESCOTT, ARIZ.—The Prescott Telephone Company has been organized.

VISALIA, CAL.—W. H. Alford will present a petition for a franchise to establish a local telephone system.

CANYON CITY, ORE.—W. D. Fletcher offers $1,000 bonus to any one who will put in a telephone line from that city to Burns.

CHATTANOOGA, TENN.—Clarence C. Duncan is the new manager of the East Tennessee Telephone Company's plant in this city.

FLORENCE, ALA.—Charles Briard, of Augusta, Ga., has been appointed manager of the Florence-Sheffield Telephone Exchange.

AUBURN, MO.—A franchise has been granted to the Auburn Telephone Company.

INDIANAPOLIS, IND.—The Board of Works will not grant a longer franchise than ten years to the Phoenix Telephone Company.

BAY CITY, MICH.—The Anthony Telephone Co. which was granted a franchise in this city, has not accepted it, and the time for its acceptance has expired.

LANCASTER, PA.—A telephone company has been formed with the following officers: President, S. R. Dickey, Oxford; secretary and treasurer, Eli McKissick, Oxford.

ARGENTINE, KAS.—The telephone connection between this city and Rosedale has been completed by the Silver City Telephone Company.

GREAT BARRINGTON, MASS.—A telephone line from the central office at Great Barrington to the post office at Alford will be built at once by the New England Telephone company.

CADILLAC, MICH.—The common council of Cadillac has ordered the Bell Telephone Co., which no longer does business in that place, to remove its poles and wires from the streets.

CARTHAGE, MO.—The Carthage Electric Telephone Company has been formed; capital, $5,000. Incorporators: T. J. Clark, E. C. Clark, G. E. Wheeler and others.

FALL RIVER, MASS.—The Southern Massachusetts Telephone Company has filed an acceptance of its franchise for underground wires. One provision in the grant is to the effect that the city may purchase the conduits.

LANSING, MICH.—If the Lansing Telephone Company can get a franchise a new telephone exchange will be in operation at the capital city shortly after July 1. D. A. Reynolds is at the head of the enterprise.

HARTFORD, WIS.—The Badger State Telephone Company of Hartford has organized and will soon be incorporated. This company has constructed a telephone line from Neosho to Woodland and Iron Ridge, and intends to extend it to other points north.

MCBAIN, MICH.—Wires are being strung from this place to Cadillac, and McBain will soon have telephone connection with Lake City, Lucas and Cadillac. Gillis McBain and O. O. Dunham of this place and H. W. Sill are the proprietors of the new line.

SYRACUSE, N. Y.—A telephone company is being formed by local capitalists to be known as the Mutual Automatic Telephone company, with ample capital already subscribed for the purpose of laying subways and giving the people of the city a perfect service.

NEGAUNEE, MICH.—The new telephone system which will soon be put in at Negaunee and Ishpeming by the Marquette County Telephone Company, will be extended to Palmer. The cost of building the line from Negaunee to Palmer will be paid by Clark Kirkpatrick and it will be his personal property.

ST. LOUIS, MO.—The New Improved Underground Telephone System is to be known as the St. Louis Citizens' Underground Telephone Company. The ordinance granting the new company the right to lay conduits underground has passed a second reading in the Council.

GRAND RAPIDS, MICH.—The new Harrison Telephone Company perfected its organization by electing as officers: President, E. B. Fisher; vice-president, C. F. Rood; secretary, Amos S. Muzzelman; treasurer, James M. Barnett; manager, J. B. Ware. The new company will at once place $30,000 more bonds on the market, and immediately after July 4, will begin building the exchange. It is proposed to reduce rates to $20 and $30 per year for telephone service, the latter for business houses.

MANNINGTON, W. VA.—The Fairmount and Mannington Telephone line has been completed through to Fairmount.

OBERLIN, O.—The Oberlin Telephone company has been formed; capital stock $10,000.

STEUBENVILLE, O.—The Phoenix Telephone company has been granted a franchise at Steubenville by the city council.

DECATUR, ILL.—The entire plant of the Citizens' Mutual telephone company, worth $25,000, together with franchise has been sold to John A. Brown of Decatur, as trustee for a syndicate.

TOPEKA, KAS.—The Topeka Telephone & Electrical company has secured the contract for putting in a telephone system at Manhattan with 100 telephones.

PRESCOTT, ARIZ.—A telephone franchise was unanimously granted Charles F. Hoff of Tucson by the City Council, to put in a Bell telephone system in Prescott.

LOUISIANA, MO.—The La Crosse Lumber Company has arranged to put a telephone line in from Louisiana to Mexico to go through Curryville, Vandalia, Farber, Laddonia and Rush Hill.

MIDDLETOWN, N. Y.—J. E. Iseman, A. B. Wilbur, J. J. Silk, Dr. T. D. Mills, C. S. Mills, and L. S. Stivers, as the new Orange County Telephone Company have been granted permission to erect poles, etc.

SEDALIA, MO.—A new company has applied for a franchise to build and operate a telephone exchange and conduit system in Sedalia. The proposed rate is $2 for business houses and $1.50 for residences.

GRAND RAPIDS, MICH.—The Citizen's Telephone Company has been organized and the following directors chosen: James M. Bennet, S. B. Jenks, C. F. Rood, Amos S. Musselman, C. E. Perkins, E. A. Stowe, W. J. Sturat, Charles R. Sligh, E. Fitzgerald and Phil Graham. The capital stock of the new company is $100,000 of which $60,000 has been paid in.

EDGERTON, IA.—Negotiations are under way for the construction of a telephone line connecting Bonested, in Gregory county, and Wheeler, Edgerton and Bloomington with Armour. The line is to be a continuation of that from Stuart, Neb. to Bonestead and will make a valuable circuit for this section of country.

SHARPTOWN, MD.—The directors of the Bethel, Laurel & Sharptown Telephone Co., which was recently granted a charter, have organized by electing J. Dallis Marvil, of Laurel, Del., president; John M. C. Moore, of Bethel, Del., secretary, and A. W. Robinson, of Sharptown, Md., treasurer. The company will construct a telephone line from Laurel to Bethel and Sharptown.

ALICE, TEX.—A new telephone company has been organized with a capital stock of $10,000, with the following officers: John Wade, president; George Newberry, vice president, and L. G. Collins, secretary and treasurer. The new enterprise will be known as the Alice, Wade City and Corpus Christi Telephone Company.

HENDERSON, KY.—Articles of incorporation of the Henderson Harrison Telephone Co. have been filed. The capital stock is stated as $15,000 in shares of $100 each. The incorporators are Montgomery Merritt, W. S. Johnson, O. W. Rash, S. K. Sneed, James E. Rankin, Chas. E. Dallam, all of Henderson, and H. K. Cole, of Louisville, Ky.

MILWAUKEE, WIS.—A new schedule of telephone rates has gone into effect in Milwaukee on July 1, and the telephone subscribers will be given a number of concessions. The principal concession is the reduction of the standard rate of $90 a year on the basis of 1,000 calls, within a radius of three-quarters of a mile from the central telephone exchange, to $75 a year.

LINCOLN, ILL.—A new organization to be known as the Logan County Telephone Company, the controlling spirits being E. D. Engart, of Lincoln, and J. H. Snyder, of Mt. Pulaski, have closed a contract with the Lincoln Mutual Telephone Company under the terms of which a line is to be built from this city to Mt. Pulaski within three months.

OXFORD, PA.—The proposed telephone line to extend along the L. O. & S. R. R. from Oxford to Peach Bottom will be built in the near future. The following officers and directors were elected at a meeting held last week: President, S. R. Dickey; Secretary and Treasurer, Eli McKissick: Directors, E. B. Patterson, S. R. Dickey, B. S. Patterson, E. L. McSparran, J. K. Fairlamb, W. C. Wood, J. M. Shawalter, Eli McKissick and J. L. Walker.

BARBERTON, O.—A franchise has been granted to the Portage Telephone Company and another to B. G. Holloway. Both were given the right to own, operate and maintain a telephone system in the village of Barberton. Now it has been announced that still another telephone company has come into existence, and is known as the Magic City Telephone Company. It has been incorporated by business men.

LEGAL NOTES.

TAXATION OF THE TELEGRAPH.—THE WESTERN UNION'S SUIT AGAINST THE STATE OF INDIANA.

The case of the Western Union Telegraph Company against the various county auditors and county treasurers of the state of Indiana has been filed in the United States Supreme Court for docketing. It comes from the Supreme Court of Indiana on a motion for a writ of error. The case involves the constitutionality of the state law of 1893 providing for an extra tax on telegraph, telephone, sleeping-car, and express companies. The Western Union Company alleges that the law did not pass the Senate until after the expiration of the constitutional limit of the time of its session and that the valuation of its property as a basis for state taxes as fixed by the state board was exorbitant, amounting to $357 per mile, or a total of $3,297,652 for the entire state, exclusive of real estate, machinery, etc., subject to local taxation. The company asserts that $686,196 would be a fair valuation. It appears that the valuation fixed by the state board was made upon the basis of the New York quotation of Western Union stock, which the company contends was in all respects unfair and inequitable. The company asks to have the county officers enjoined from the execution of the law.

LOUISIANA ELECTRIC LIGHT CO. NOT TO HAVE A RECEIVER.

Judge Pardee of the U. S. circuit court, New Orleans, has rendered a decision in the case of the United Electrical Securities company; the New York Loan and Trust company and the New Orleans Traction Company against the Louisiana Electric Light Company for the appointment of a receiver to protect the property from being wasted.

The court refused to appoint the receiver, declaring the Louisiana Electric Light Company not insolvent, but issued an injunction prohibiting the officers of the company from transferring or disposing of stock, or from doing aught else than managing the affairs of the corporation until February, 1896, when there will be an election of a new board of directors.

TESLA PATENT LITIGATION.

The Suburban Electric Company of Philadelphia has filed an answer in the United States Circuit Court to the suit brought against it by the Westinghouse Electric and Manufacturing Co. and Tesla Electric Co. for alleged infringement on various patents. The Suburban Co. denies having made infringement as alleged, and claims that the patents of the complainants for electro-magnetic motors are void because the alleged inventions and improvements and all the substantial and material parts thereof were disclosed and well-known in the art long prior to any alleged inventions held by the complainants.

SOCIETY AND CLUB NOTES.

ELECTRICAL SUPPLY DEALERS IN BUFFALO ASSOCIATE.

The electrical supply dealers and contractors of Buffalo have organized an association, with the following membership: F. P. Jones & Company, the F. P. Little Electrical Company, C. & S. Company, Buffalo Electric Company, Jaynes Electrical Company, W. A. Fenn, American Electric Supply Company, Theabaud & Churchill, T. H. Flach & Son, Herman L. Peters. The officers are: F. P. Jones, president; Leon L. Miller, vice-president; W. C. Jaynes, treasurer; Wells Dygert, secretary.

MARRIED.

ELECTRICAL DISPLAY AT THE BENALLACK-ANTHONY WEDDING.

The wedding of Mr. Wm. T. Benallack, and Miss Hettie Laurine Anthony was solemnized at the residence of the bride's mother, Mrs. L. M. Anthony, Detroit, June 19. Mr. Benallack has for some time held the position of Electrical Inspector for the Michigan Inspection Bureau of Detroit. A special feature of the decorations was the electrical display arranged by Messrs. Hartwig & Miller of the American Electric Co. and Mr. E. Phillips of the Peninsular Elec. Lt. & Power Co., as a compliment to Mr. Benallack, and which consisted chiefly of tiny colored miniature electric lamps placed in floral set pieces, and among the palms, &c. Numerous beautiful and costly presents were received from the friends of the young couple, among which was a silver water service presented by the fellow employees of Mr. Benallack in the Michigan Inspection Bureau.

Reports of Companies.

ANNUAL REPORT OF THE WESTINGHOUSE ELECTRIC & MFG. CO.

The annual report of the Westinghouse Co. was distributed to the stockholders last week. It opens with a reference to the fine new shops at East Pittsburgh, illustrated in these pages some months ago, and mentions the fact that the company now has room there for between 4,000 and 5,000 men, while some 20 acres are still available for extensions. Stockholders are invited to inspect the place on July 17, when the annual meeting will be held and when special railway arrangements are to be made.

Deducting expenses of removal, the net profit shown for the year is $711,909, which is considered excellent in view of the various adverse conditions prevailing through the year.

For six years the company has been interested in the United Electric Light and Power Company, of New York, and the Brush Electric Company, of Baltimore. In the last year both of these companies have carried through financial plans which have put them on a prosperous business basis, and have given a large increase to the value of their securities, held by the Westinghouse Company. The United Company has acquired almost all the stock of the Brush Illuminating Company and of the United States Illuminating Company, both of New York. It has contracted with the Westinghouse Company for ten complete electrical outfits of 1,000 horse power each, and for all the converters and other needed apparatus, half of these outfits having been used for the World's Fair lighting. On the completion of the above contract, the Westinghouse Company will have in securities of the United Company: First mortgage bonds, $913,000; preferred stock, $550,400, and common stock, $411,700, having already received of this amount, under the terms of the reorganization, for material, unsecured notes, claims, and for a cash subscription of $200,000, first mortgage bonds, $548,000; preferred stock, $187,500, and common stock, $411,700. The company is doing a business of about $800,000 a year from the old plant.

In the reorganization of the Brush Company the Westinghouse Company subscribed for $40,000 first mortgage 5 per cent. bonds, and took in payment for machinery $170,000 first mortgage bonds, making a total holding of $210,000 first mortgage 5 per cent. bonds. The Westinghouse Company also holds 5 060 ($100) shares of the common stock, out of a total of 7,292 shares outstanding. The Brush Company has three of the World's Fair 1,000 horse power engines and generators, and has been supplied with a large amount of other electrical apparatus, and will be hereafter, as will also the United Company, a constant purchaser of Westinghouse apparatus and supplies. The new Baltimore station was recently illustrated in The Electrical Engineer.

As to the World's Fair contract, all the bonds for its execution have been cancelled, and the company has received from President Higginbotham a letter of praise and thanks.

After a full consideration of the subject, the Board of Directors has authorized the issue $1,250,000 ten year 5 per cent. collateral trust bonds, secured by bonds and stocks held by the company, provision being made in the deed of trust for the sale of a portion or all of the securities and for the cancellation of the corresponding amount of the collateral trust bonds secured thereby. It is proposed to fund out of the proceeds of this issue of collateral trust bonds an equal amount of debt, a greater part of which has been created in the building of the new works, the purchase of new machinery, and the outlays in connection with the financial plans of the United and Brush companies.

The Company practically owns the Westinghouse Electric Co. Limited, of England, holding $782,000 preferred and $1,307,400 common out of $2,322,750. It is doing a business at a profit of about 5 per cent. on a valuation of $1,000,000.

Cheerful reference is made to the Company's brilliant successes in litigation respecting the incandescent lamp, the feeder and main case and the Bate refrigerator suits. The long delay in the McKeesport carbon filament appeal to the Supreme Court is interpreted favorably to the claims of the Sawyer-Man patent.

In view of the growing importance of street railway conduit work, notice is drawn to the electro-magnetic system now exhibited at the Company's offices, 120 Broadway, and recently illustrated and described in The Electrical Engineer. The system is now in use in Washington and at East Pittsburg.

Coming to the important subject of the Tesla patents, the report says: "Your Company owns the exclusive right to manufacture and sell apparatus under the patents of Nikola Tesla, covering the use of multiphase alternating currents for power distribution. The rights under these patents are of great value, for developments indicate that it is only by means of Tesla's inventions that elevated and long lines of railways can be successfully operated, and that power can be most economically distributed over wide areas, and throughout workshops. All of the machinery in your Company's new factory at East Pittsburg is driven by Tesla multiphase motors, and in such a successful manner that orders for like apparatus have followed its inspection.

"The 5,000 H. P. generators contracted for by the Niagara Cataract Construction Company have been put in successful operation, and other important installations for power transmission under the Tesla Patents have been made in various parts of the country.

"Recently your Company has fitted a short branch of the Pennsylvania Railroad with ordinary electrical apparatus for the propulsion of standard cars, and the tests have been entirely satisfactory. Your Company is, however, pushing forward the manufacture of multiphase motors under the Tesla Patents for practical tests in running standard cars on elevated roads and long lines, the success of which will be of especial importance, for it will insure to your Company a large amount of trade for which your rivals will have no right to compete.

"Suits under the Tesla Patents are pending against the Stanley Electric Manufacturing Company of Pittsfield, Mass., and the Thomson-Houston Company. In the latter case on application made by attorneys of your Company, the defendants have been limited to the 7th of October within which to close their testimony, it being the intention of counsel to push this and all cases of infringement to a hearing in order that your Company may enjoy the exclusive privileges to which it is entitled.

"While heretofore a very large percentage of the business of the country has been done by means of apparatus using continuous currents, it is now estimated by experts that the percentage will change so that in the near future the bulk of the business will be done by means of alternating current multiphase apparatus, involving the use of Tesla's important inventions."

The balance sheet presented is as follows:

Balance Sheet, March 31st, 1895.

ASSETS:			
Cash in Banks			$302,880 89
Bills receivable			80,183 81

The Westinghouse Elec. & Mfg. Co. has declared a quarterly dividend of 1¾ per cent. on its preferred stock payable July 1.

A large engine concern write us: "We make a practice of looking over the pointers and suggestions in your paper and in other journals, and we are fairly convinced that there is more valuable news of this kind in The Electrical Engineer than in any other journal which we read."

Trade Notes and Novelties

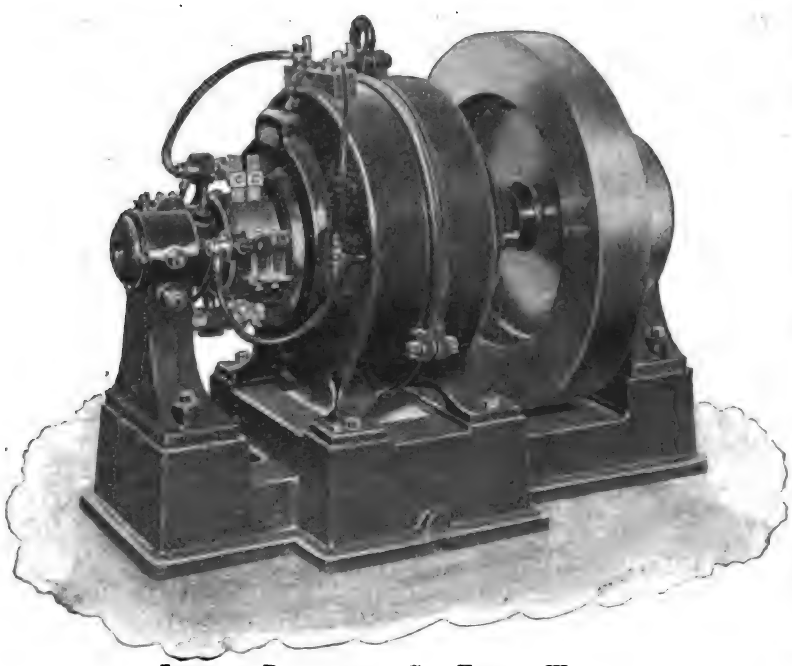
AND MECHANICAL DEPARTMENT.

PELTON WHEELS FOR ELECTRICAL WORK.

The Pelton Water Wheel Company, San Francisco, supplied a few months ago two wheels aggregating 600 H. P. to the Silverton mines in Colorado for running an electric transmission plant, the operation of which has been so satisfactory that a duplicate of the plant has now been ordered. The company have also an order for a 400-H. P. station for the Concheno mine in Mexico, together with an electric light plant for the mine and works. They report also several other orders from Mexico and Central America, which compels them to double up their force, and they are now running their works both night and day.

LUNDELL COMPOUND WOUND GENERATORS APPLIED TO GAS ENGINE SERVICE.

We illustrate a modification of the well-known Lundell generator as constructed for service in isolated lighting when the motive power is furnished by a gas engine. Great improvements have been made in the last few years in gas engines, but up to this date no gas engine above 5 H. P. has been available, it is said, that could be relied upon to operate at uniform speed. In order to provide for absolutely uniform electro-motive force, or, in other words, uniform incandescence of electric lamps in such a plant, the Interior Conduit and Insulation Co. have built a special generator which carries in addition to the belt pulley, a fly wheel of heavy rim weight. In this fly-wheel is stored up sufficient energy to compensate for the slight inherent irregularities in the speed of the gas engine. It will be observed that extra care has been taken in furnishing substantial pedestals, heavy shaft, and modern self-aligning and self oiling bearings. The efficiency of the dynamos is from 86% for the small machines to 93% for the largest machines.



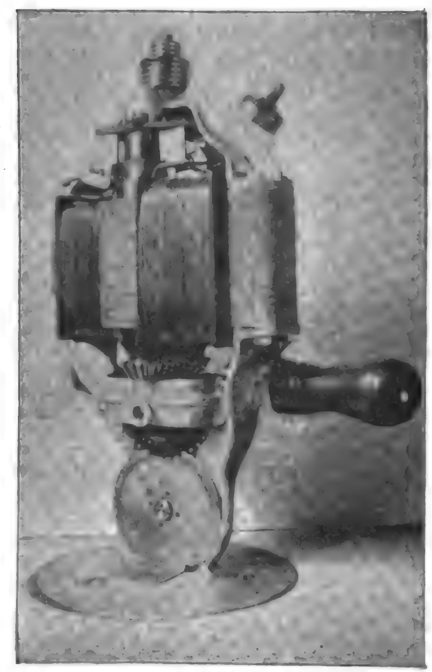
LUNDELL DYNAMO FOR GAS ENGINE WORK.

FAN MOTOR HAIR DRYING.

The *Evening Sun* makes the very sensible remark that fan motors are not yet as well known by the seashore as they ought to be. Indeed, no place can be hotter than a seaside resort with the wind blowing the wrong way or not blowing at all. But the paper suggests the use of fan motors not only for cooling purposes but as a means of drying the hair of women bathers. It says that women are often kept out of the water, not from fear of getting their suits wet but because it takes so long to dry their hair; and it adds that any one who will equip the bathing resorts with fan motors for hair drying will make a very good thing out of it. The practice is already growing up among city hairdressers, who find it very popular with their customers.

ELECTRIC CLOTH CUTTERS.

The Electric Cutter Co., New York, after many experiments, have now had their cloth cutting device on the market for nearly a year. The machine operates on a 110-volt circuit developing ¼ H. P. and is furnished with switch, flexible cord and socket. There are two two-pole motors in each machine, the armatures of which maintain a perpendicular position, each connected by gearings with the circular knife blade below. The motors used by the Cutter Company, have special windings, and in order that the operator may not lose sight of his work, the fields are mounted in somewhat of a rhomboidal shape. The cutter works successfully with four or five inches thickness of cloth, its record being a cutting of 288 separate pieces—or just about double the capacity of the steam cutters now in use in some tailoring establishments. Another advantage is the portability of the machine which may be operated wherever current is found. With the steam cutter the tailor after the pattern is chalked on the top piece of cloth, must carry that cloth to the machine, with consequently some natural disarrangement of the goods, and a delay in subsequent rearrangement; while with the electric cutter, the cloth once marked need not be disturbed, the cutter coming to it. The Cutter Company tried many methods of manufacture, building several types of motors and employing up-and-down as well as circular knives before they hit on the right thing; and the satisfaction caused by the perfected machines assures them that the time spent in experiments was not altogether in vain. Indeed with their experience the Company feel competent to build any size or style of motor for special uses.



ELECTRIC CLOTH CUTTER.

The cutter requires little or no attention. In the event of the knife dulling, a device for sharpening without removing the blade is easily applied.

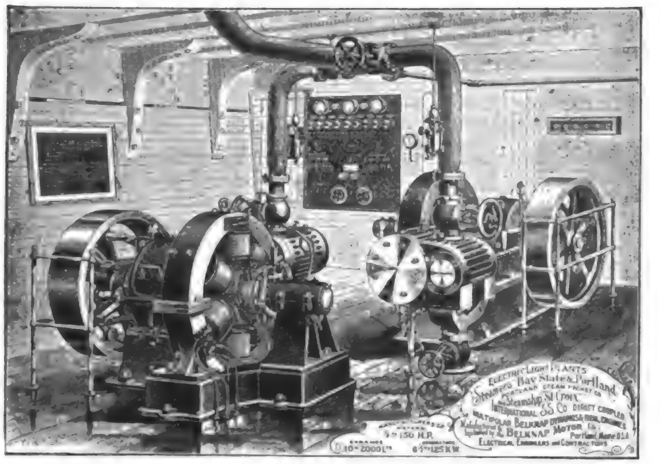
NEW YORK NOTES.

EVERETT W. LITTLE, General Manager of the Interior Conduit & Insulation Co., spent July 1st in Philadelphia, and as a result the new Hotel Walton on Broad street will be wired throughout with the brass armored conduit system. The Hotel Metropole, adjoining, will be a part of the new Hotel Walton and both will be under the same management, that of Stafford & Whittaker of the Imperial of New York. Angus S. Wade is the architect and Harry S. Smith & Co., Ltd., are the electrical contractors.

MR. E. L. BARR, well known to the electrical trade through his old connection with the Canadian General Electric Co. and more recently through his work as traveling salesman for the Wallace Electric Co., Chicago, has been appointed secretary of the latter concern, which is closing out its merchandise business and will hereafter devote itself to acting as western representative for the leading electrical specialties it is now handling.

THE BELKNAP MOTOR CO.'S MARINE PLANTS.

The accompanying illustration represents the electric light plant on the new steamer "Bay State" of the Boston & Portland Line recently installed by the Belknap Motor Company, of Portland, Maine. The engines used are the "Ideal." The dynamos are multipolar slow speed machines of 400 lights capacity each, but either machine will carry the entire load amounting to 540 lights. It has become a general practice to use duplicate plants for marine work so that in case an accident should happen to either engine or dynamo the duplicate machine can do the work. This plant does great credit to the above-named company, and has secured for them the installation of two direct-coupled machines for the



BELKNAP SHIP LIGHTING PLANT.

steamer "Portland," and also for the "St. Croix" which is practically under the same management.

The wiring was done under the direction of Mr. Elmer E. Emmons, one of the most expert workmen in this line in the New England States. Eight main circuits controlled at the switchboard in the dynamo room lead to sixteen different distributing boxes located in different parts of the boat. These distributing boxes have glass fronts secured with lock and key, and are under the control of the steward of the boat.

The fixtures are of the latest design with opalescent globes and shades. The dining saloon is fitted with ground glass globes, which gives this part of the boat a very cheery and pleasing appearance. The freight deck is supplied with guarded fixtures. The boat at night presents a brilliant spectacle being a veritable floating palace and surpassing in all its appointments anything that can be found in eastern waters, the Sound lines alone excepted. The addition of this new boat has been the means of popularizing this line with the best class of the traveling public.

THE AMERICAN MARBLE & TOY MFG. CO.

The American Marble & Toy Mfg. Co., of Akron, Ohio, has recently discovered and secured the control of a natural inexhaustible bed of porcelain clay, specially suited for insulators. The porcelain clay burns a hard, vitreous, glassy, inside body, that resists all moisture, ink, acid, etc. The company now turns out as a specialty electric insulators and tubing. The tubes in white, or dark brown, as desired, are quoted at about one-half the price of ordinary unglazed porcelain.

WESTERN NOTES.

THE WESTERN TELEPHONE CONSTRUCTION Co. report that they are very busy supplying orders for their make of telephones. They have recently received the following contracts from Washington, part of which have been already put up, and are giving perfect satisfaction; Patent Office, 150; Department of Justice, 30; District of Columbia, 200.

THE FRANKLIN ELECTRIC Co. has been awarded the contract to re-construct the electric light plant at Pawnee City, Neb., and to install an 85 horse power engine and a 500 light alternating dynamo together with station apparatus and line construction. The Franklin Co. has also been awarded the contract to re-build the electric light plant at Ossawatomie, Kansas. This plant was destroyed by fire about a year ago and meanwhile the city and inhabitants have been without lights. The work is being rapidly pushed and the lights will be started up there before Aug. 1.

THE FALLS RIVET & MACHINE CO.

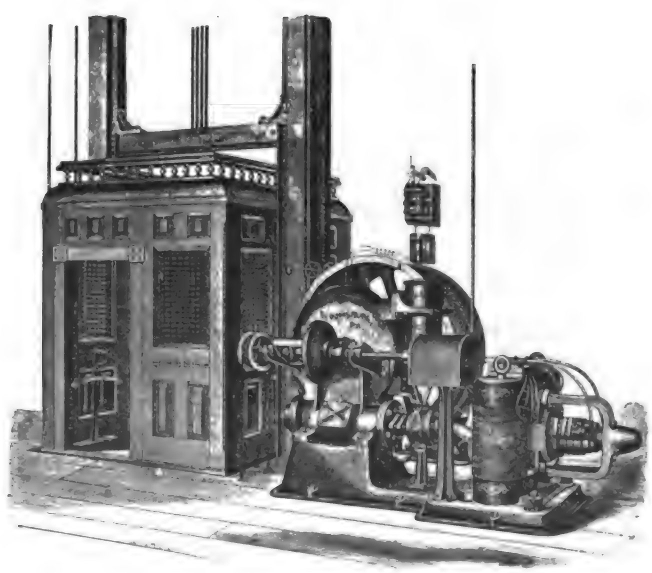
The Falls Rivet & Machine Co. of Cuyahoga Falls, O., write us as follows:—We are pleased to say that our business is picking up somewhat, and are very much elated over an order which we have just received from the Diamond Match Co., of Barberton, Ohio, for a complete outfit of power transmitting machinery for equipping the large factory which they are now erecting at Liverpool, England. We have already equipped several of their factories in this country, and the fact that they favor us with the order for their foreign factory leads us to believe that they are very well pleased with the work which we have furnished them in the past. We think this will be quite a card for us, inasmuch as the material which we are furnishing will go right into the manufacturing district of England, and where a large amount of power transmitting machinery is made.

THE PENN ELECTRIC ELEVATOR.

THE accompanying illustration shows the latest form of electric passenger elevator, built by the Penn Elevator Co., of Bloomsburg, Pa. The motor and machine are mounted on a heavy bed-plate, and the motor is thoroughly insulated from it. The worm and wheel is of the Hindley type, and being cut from solid blanks and running in oil insures the smooth running of the car. The worm is made of steel, and hard metal collars and buttons are provided for taking the thrust at the ends.

The electric brake is so arranged as to release the brake wheel positively when the current is turned on to ascend or descend. Should any accident happen to the main circuit the brake would immediately be applied, thus avoiding any danger of the car running down too fast. The motor and reversing switch are constructed with special attention to secure durability, and the motor is provided with self-adjusting carbon brushes, self-oiling bearings, proper rheostats and safety fuses.

The electric slack cable shifter is a special feature of the machine; the operation is such that in the event of the main cables



THE PENN ELECTRIC ELEVATOR.

becoming slack from any cause (such as the car getting caught on guides while descending), a switch is disconnected by mechanical means and the machine immediately stopped, preventing entanglement of the cables.

The machine is provided with the usual automatic stops for stopping the car at upper and lower landings. The automatic safety clutch, which is connected with the car, is operated by a governor at the top of the hatchway, which operates either in the event of the giving way of the main cables or from any cause which increases the speed of the car beyond the normal.

THE BALL ENGINE CO.'S ORDERS.

The Soldiers' Home at Orting, Wash., has recently purchased an engine for electric light purposes from the Ball Engine Co. of Erie, Pa.

The Salamanca Water Works Co., Salamanca, N. Y., are putting in an electric light plant. Two 175 H. P. tandem compound Ball engines, will furnish the power.

The Norfolk & Ocean View Street Ry. Co., Norfolk, Va., are installing two 125 H. P. Ball tandem compound engines.

THE WHITNEY ELECTRICAL INSTRUMENT CO.'S NEW DIRECT CURRENT SWITCHBOARD INSTRUMENT.

The Whitney Electrical Instrument Co. of Penacook, N. H., has put upon the market a new direct current switchboard instrument of more than average merit. These instruments are handsomely mounted in black enameled iron cases with nickel fronts, are thoroughly dust proof, and are not affected by external

New Whitney Direct Current Switchboard Ammeter.

influences. They will remain constantly in circuit without showing a heating error, and are quite dead beat. Other points of advantage are their accuracy—they are guaranteed within one per cent. of absolute accuracy—and the legibility at a distance, of their scale, which is seven inches in length, with large and clear divisions.

M. R. RODRIGUES.

Mr. Rodrigues, in addition to his "Premier Products" has received many orders for other material, including binding posts, fan guards, brush holders and commutators, one house alone ordering 8,500 of the last named. The result is that larger quarters are necessary and work has been started on a new building which when completed will give Mr. Rodrigues facilities for quick manufacture.

NEW YORK NOTES.

The Stock Market last week was dull owing to the holidays, and almost without any change. Toward the close, however, better tendencies reasserted themselves, and prices became stronger.

Abendroth & Root Manufacturing Company, makers of the Root improved water tube boiler, recently received a cable order for three one hundred and thirteen horse power Root boilers, to be shipped to Johannesburg, South Africa.

Mr. Charles E. Chapin has settled up affairs satisfactorily with creditors on the basis lately agreed to, and is actively pushing business as a manufacturers' agent at 136 Liberty street with bright prospects improving as the times grow better.

Mr. Fred. Reckenzaun, the electrical engineer, is going abroad for rest, and will spend the summer in Switzerland and Austria. He will make note of current progress abroad, and will be back in the Fall to carry out several projects now under consideration.

Mr. R. B. Corey, Havemeyer Building, has just sold 75 incandescent arcs to the parties who have the contract for lighting West Asbury Park. These will be run on a 500 volt circuit 8 in series. Some have already been on trial and give the utmost satisfaction,—leading to this larger order.

Mr. H. L. Brevoort, who died last week was not generally known among electricians, but his work as a patent expert was of a high order. His tastes ran in the direction of electricity, and he made several ingenious improvements and inventions, chiefly in association with Mr. I. L. Roberts.

The Electric Boat Co., of New York has been formed, with offices in the Electrical Exchange, Liberty Street. It will handle the boat described recently in The Electrical Engineer, having a flexible motor-and-propeller shaft. It will make and sell electrical boats and electrical appliances generally. The directors are Frank S. Allen, I. T. McDowell and O. H. Dewitt of this city. One of the boats is now running on Central Park waters.

WESTERN NOTES.

The Bullard Electric Co. has been formed at Chicago to manufacture electrical apparatus, with a capital stock of $25,000. The incorporators are C. W. Bullard, A. S. Bullard and Carl E. Kammeyer.

The Gould Co., 32 North Canal street, Chicago, Ill., has closed a contract with the city of Oregon, Ill., for an electrical pumping plant to consist of one of Goulds triplex power pumps, size 10" x 12" having a capacity of 500 gallons per minute. The pump will be operated by electric motor.

Max A. Berg, Secretary of the Wallace Electric Company, has resigned his position as an officer of that company taking effect July 1st. Mr. Berg will take a well earned rest, and no doubt will become associated with the electrical industries again in the near future.

The McClean Armature Works are very busy at their shop on 197 Canal street on general electrical repair work, and have a very interesting working model of the Baird Electric Conduit Street Railway which they will be pleased to show to all callers who are interested in this very important mode of transportation.

Mr. T. I. Stacy, secretary and treasurer of the Electric Appliance Co. has settled down to work very promptly after his trip to the Rockies, and finds business in a most hopeful and encouraging condition. There is hardly a line in which activity does not prevail, or which does not promise briskness in the Fall.

The Electric Appliance Company have just made some improvements in the manufacture of their excellent black and white "Acme" tape. It has been severely tested in the dryest parts of the country, over considerable periods of time, without showing any intention of hardening or drying out. It is unquestionably a good thing.

The St. Louis Machine Works report among its recent orders for St. Louis Corliss engines the following: Los Angeles, Cal., Electric Co., 400 H P compound; Municipal Electric Co., Decatur, Ill., 350 H. P; Standard Electrical and Gas Works Co., Independence, Ia., 150 H. P.; Union Depot Street Railway Co., St. Louis, 700 H. P. heavy duty; and nearly 1000 H. P. more to various concerns, chiefly in the milling industry.

Field & Hinchman, Detroit.—Last February this firm decided to give up the contracting business and devote themselves entirely to consulting electrical and mechanical engineering. Their business has increased so fast that they found it necessary to move to larger offices and are now at 25-26 Hodges Building. They are at present engaged to superintend the following electric installations: New Valpey Building, Central High School, Masonic Temple, W. H. Frear's Bazaar, Troy, N. Y., D. Scotten & Co.'s factory and residences, and a number of smaller installations. In addition to the above they have recently completed the superintendence of electric light plants in several other buildings.

PHILADELPHIA NOTES.

The Helios Electric Co., in order to secure more room and better facilities for manufacturing, is removing from its present location to Nos. 1225-7-9 Callowhill street, Philadelphia, where all communications should be addressed after July 20, 1895.

NEW ENGLAND NOTES.

The Beacon Lamp Co., L. E. Whicher, treasurer, has absorbed the old Beacon Vacuum Pump and Electrical Co., and has all its assets together with $40,000 in cash for enlarged operations.

The Bernstein Electric Co. of Boston, Henry B. Cram, treasurer, is starting a New York office at room 95, No. 39 Cortlandt street. It will be in charge of Mr. A. L. Fenton, who is already well known as an incandescent lamp representative. He will handle the Bernstein lamps in New York city and vicinity, New York State, Pennsylvania and New Jersey.

Mr. Henry Kaliske will hereafter be known to his many friends as Mr. Henry Sachs, the family having secured legal permission for the change of name. Mr. Sachs has resigned his position, long held, as manager of the Beacon Vacuum Pump & Electrical Co., and his address until further notice will be 21 Harcourt street, Boston.

The Evans Friction Cone Co. existed under a partnership composed of W. A. Russell and G. Frank Evans and has now been dissolved. Mr. Russell is authorized to settle up the affairs of the old concern, while the business will hereafter be carried on by Mr. Evans in his own name and for his own benefit at 85 Water street.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

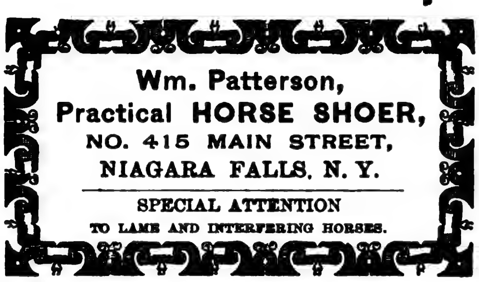
THE
Electrical Engineer.

Vol. XX. JULY 17, 1895. No. 376.

THE BURTON LIQUID ELECTRIC FORGE.

BY

W. W. Ker

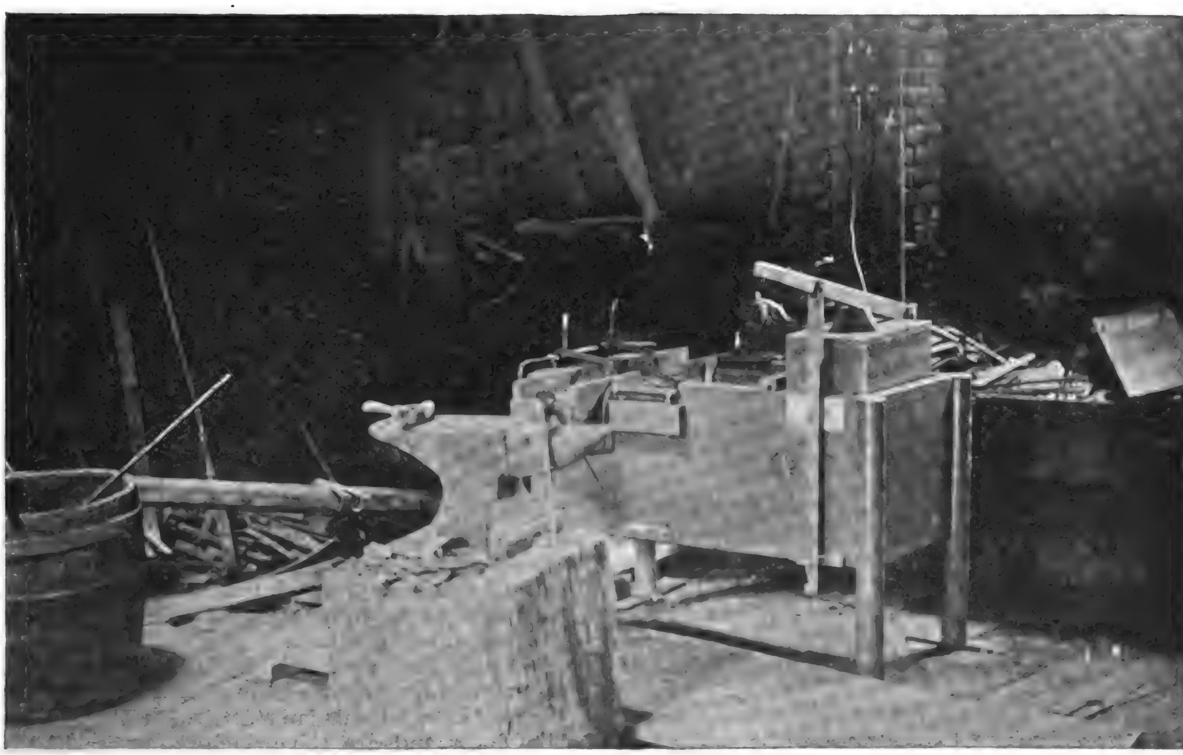


THE decomposition of water by the electric current is an old and well known phenomenon, but the heating of the negative electrode by the ignition of the liberated hydrogen gas has only recently attracted the attention of those interested in electric heating, welding and forging.

The first method of heating a piece of metal by the liquid forge was to connect a lead plate to the positive wire and a pair of tongs to the negative. Then by grasping with the tongs the metal to be heated and immersing it in the vessel containing the positive electrode and a good conducting solution of dilute sulphuric acid or soda, the metal will begin to increase in temperature and if the operation is continued long enough will melt. All the time it is increasing in temperature it is in view of the operator and can be withdrawn when the desired heat is obtained.

The above method of electric heating by complete immersion requires considerable current, and this led Mr. George D. Burton to perfect the method now used, of holding the metal to be heated in contact with the surface of the liquid, and as the hydrogen gas is given off it is ignited directly in contact with the metal which absorbs the heat generated.

The time required to heat iron varies. It takes from eight seconds for a piece of iron one quarter inch square cross-section, to one minute for a piece one inch square ; the latter required 26 amperes at 220 volts which cost, it is claimed, is less than a quarter of a cent for current. The cost of preparing a horseshoe with a coal forge, with coal at $5 per ton, is 5.58 cents ; with the electric forge, and current at 15 cts. per 1,000 watt hours, it is 2.32 cents.



THE BURTON LIQUID ELECTRIC FORGE IN A BLACKSMITHY, NIAGARA FALLS, N. Y.

From the above the economy is readily determined and all that can be said in favor of the electric motor over the steam boiler and engine applies equally well to the electric forge as against the coal forge.

The photograph from which the illustration of Mr. Wm. Patterson's blacksmith shop on Main street, Niagara Falls, N. Y., is taken was made shortly after the adjournment of

the American Institute of Electrical Engineers at Niagara Falls, last month; and the writer is indebted to Mr. Patterson for his time and the current used in the experiments made in order to demonstrate the practical possibilities of the apparatus. A 500 volt current is used derived from one of the Niagara Falls power mill plants.

The forge consists of a rectangular wooden tank with a float controlled by a handle and rack work for raising or lowering the surface of the liquid. The positive wire is attached to the lead plate suspended from the edge of the tank and shown to the left of the float. The negative wire is connected to the three work rests; two of these are used for heating articles held by tongs such as horse shoes, bolts, rivets, etc., and the other for heating particular points on a long bar of iron. This is accomplished by laying it in a trough, shown at the extreme left, on two pieces of movable fire brick, which can be separated to any required distance. The space between the two bricks determines the length of the part of the rod that will be heated, and can be regulated so as to heat a space on the rod from one-fourth of an inch in length up to the full width of the tank.

When the piece of iron is in position and the bricks are adjusted, the clamps are brought in contact with the iron; on depression of the float the solution is brought in contact with the iron; electrolysis takes place and the heat from the burning hydrogen gas is imparted to the iron. By moving the float up and down, the circuit can be made and broken at will, and in an irregular shaped piece of iron this gives the heat a chance to distribute itself throughout its mass.

The solution used in this forge consists of washing soda, 10 lbs.; borax, 1½ lbs; in 45 gallons of water. The burning hydrogen has the color of burning sodium indicating that some of the constituents of the electrolyte are gradually consumed and must be replaced, at a cost of about 10 cents per month.

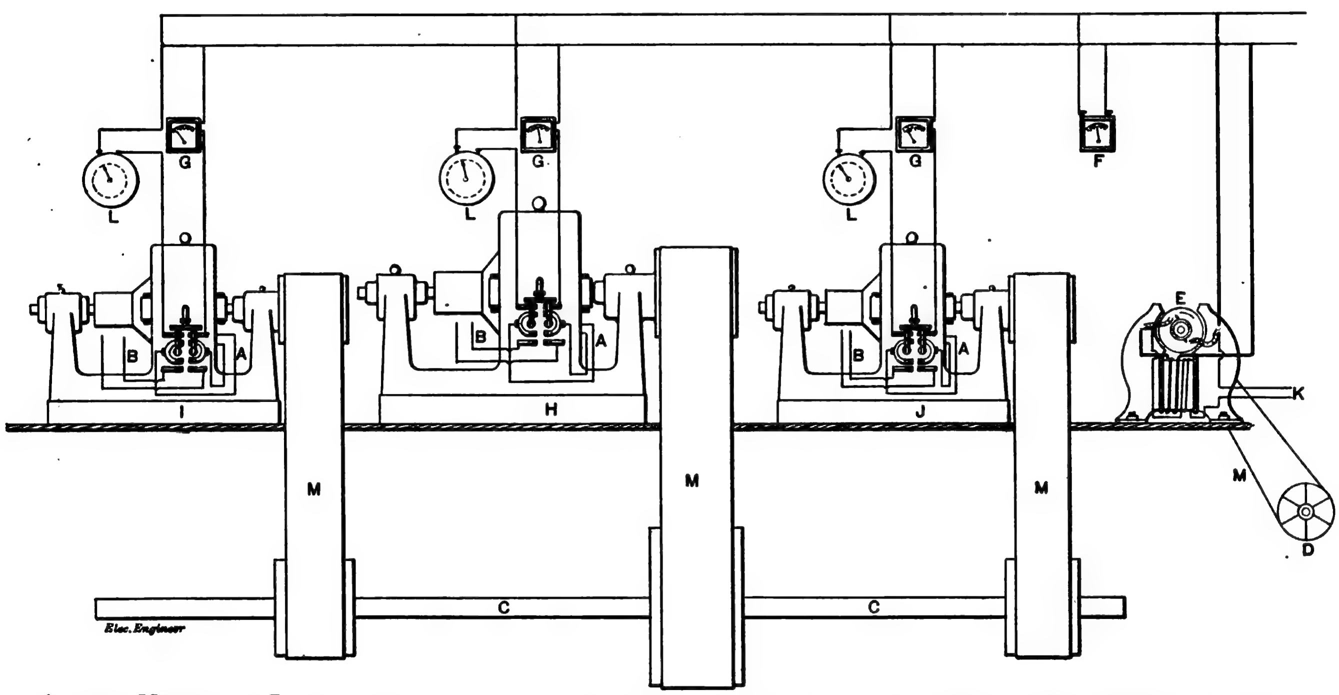
In order to show an improvement in the quality of the iron when using the electric forge, Mr. Patterson heated and hammered a thick piece of iron down to a ⅜ inch rod, and after cooling it in water was able to bend it into a circle of one-half inch radius, and on examination it showed no flaws or cracks.

Another important point in heating with the liquid forge is the absence of scale or oxide on the heated metal; this makes it possible to make a much stronger weld than by the coal forge process.

Mr. Burton, of the United States Electric Forging Co., is now applying this method of heating to the reduction of metals from their ores, and at present is operating a plant in Canada for reducing nickel. The ore is placed in a cradle and the water allowed to come in contact with it to complete the electric circuit.

STEADY VOLTAGE FOR TURBINE DRIVEN RAILWAY GENERATORS.—THE AHEARN METHOD.

The serious difficulties experienced in the operation of the water driven plant of the Ottawa (Canada) Electric Railway were for the most part overcome excepting with reference to the absolute steadiness of voltage, which it was desired should ultimately equal that of a steam driven plant. The speeding up incident to a sudden withdrawal of work on the line was always necessarily followed by increased speed of dynamos and E. M. F., and conversely frequent sudden demands for more power resulted in a "chuck" upon the armatures, more or less violent. This also reduced the strength of fields and largely contributed to the slowing up effect by neutralizing the momentum of the driving machinery, which might otherwise carry the armature over these frequent light demands if the strength of field remained constant.



Ahearn Method of Running Railway Generators by Water Power for Close Regulation, Ottawa, Canada.

During the past winter Mr. T. Ahearn, Managing Director of the Ottawa Electric Railway, and a member of the well known Canadian electrical firm of Ahearn & Soper, who built and are the principal owners of the plant at Ottawa, decided that an independently driven water wheel to operate an independent 500 volt dynamo, the current from which would be employed exclusively for the purpose of exciting the fields of his company's three street railway generators, would remove a multitude of variations of E. M. F. incident to self-excited water-driven dynamos. The necessary work to accomplish this result was completed in the latter part of January last, since which time the plant has been operated with great success upon this plan, and has greatly exceeded expectations.

By reference to the accompanying diagram it will be

seen that an ammeter G is included in each dynamo field circuit A, and placed upon each dynamo is a small double throw switch, so that in the event of an accident to the exciting dynamo or its driving wheel, the several dynamos could be self-excited by throwing the switch on each dynamo, which would connect the armature of each with its own field.

The three Westinghouse generators at Ottawa are, one of 700 H. P. shown at H and two of 400 H. P. shown at I and J, the total exciting current required for all three being less than twenty amperes. C, is the power driving shaft; D, the independent driving shaft for the exciter, and M the driving belts.

Among the many advantages of this system are the following: Steadiness of voltage, removal of the danger of burning out fields by abnormal armature speed, relief to the driving machinery, removal of fields from the line circuit preventing any possible damage to them by lightning or other cause, the prevention of damage to commutators formerly caused by short circuits upon the line throwing open the circuit breakers and short circuiting the current across the commutator. These troubles are now entirely absent. Considerable time is also saved in throwing in dynamos, which is now done without delay after the circuit breakers are reset. This formerly required a very considerable time in synchronizing fields.

The splendid success which has attended the operation of this water plant in Canada should commend it to the serious consideration of the owners of water power plants in America, which are already numerous and will always be increasing in number. And there is no doubt that some of those interested, who may attend the coming convention of the Street Railway Association at Montreal in October next will visit Ottawa to inspect personally this valuable means of removing defects and annoyances incident to the operation of electric railways by water power. Ottawa is but 3½ hours by rail from Montreal and in addition to its being the Capital of the Dominion, is a city of 50,000 live people, who boast of having an incandescent lighting installation of one lamp for each head of population, and an electric railway of thirty miles of track operating forty cars daily, which in the matter of service and equipment is unsurpassed. Ottawa is recognized as electrically of the first importance and also enjoys the proud distinction of having first solved the snow problem, demonstrating that an uninterrupted electric street railway service could be successfully maintained throughout a Canadian winter.

THE LONGEST TELEGRAPH CIRCUIT IN THE WORLD.

BY M. J. CAWLEY.

Believing that the readers of THE ELECTRICAL ENGINEER would be interested in an account of a long distance land line electric telegraphic experiment made in Australia on Sunday, May 26, 1895, I give below details of it and also a rough map showing approximately the positions and distances apart of the cities in circuit when this feat was accomplished.

On the date stated, which was selected so as not to interfere with the ordinary telegraph traffic, the officers of the electric telegraph departments of Western Australia, South Australia, Victoria, New South Wales and Queensland made arrangements for Derby, a town situated on Kings Sound on the northwest coast of Western Australia, to speak with Cape York which is the most northerly point of Queensland and of Australia.

There is no wire between those two towns along the north coast of the continent, the circuit had therefore to be made up as shown in the map.

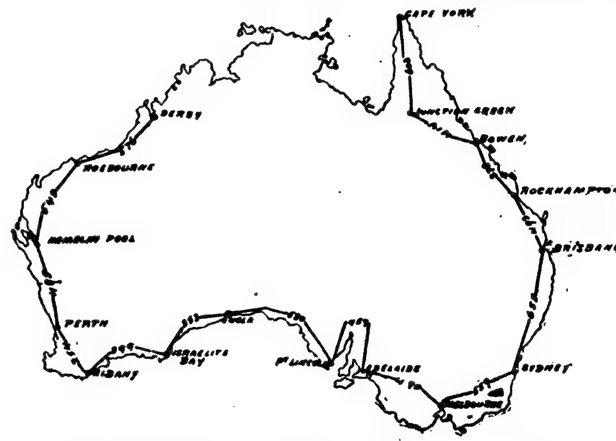
Derby, Roebourne, Hamelin Pool, Perth, Albany, Israelite Bay and Eucla are towns in Western Australia; Port Lincoln and Adelaide are in South Australia; Melbourne in Victoria; Sidney in New South Wales; and Brisbane, Rockhampton, Bowen, Junction Creek and Cape York in Queensland.

There were repeaters at the 14 intermediate offices

Station from	Station to	System.	Distance.
0. Derby	Roebourne	Morse.	576 miles.
1. Roebourne	Hamelin Pool	"	548 "
2. Hamelin Pool	Perth	"	485 "
3. Perth	Albany	Duplex.	254 "
4. Albany	Israelite Bay	"	399 "
5. Israelite Bay	Eucla	"	353 "
6. Eucla	Port Lincoln	"	580 "
7. Port Lincoln	Adelaide	"	459 "
8. Adelaide	Melbourne	Quadruplex.	490 "
9. Melbourne	Sydney	"	559 "
10. Sydney	Brisbane	"	655 "
11. Brisbane	Rockhampton	"	498 "
12. Rockhampton	Bowen	"	378 "
13. Bowen	Junction Creek	Morse.	414 "
14. Junction Creek	Cape York	"	603 "
Total			7,246 miles.

numbered 1 to 14 in the first column and the communication was carried on between Derby and Cape York over this circuit or rather series of circuits covering 7,246 miles at the rate of 11 words a minute. The operator at Cape York leads a solitary existence, not seeing a fellow human being from year's end to year's end.

The distance telegraphed over is the longest combina-



7.246 MILE TELEGRAPH CIRCUIT IN AUSTRALIA.

tion of land lines that has ever been used jointly on the continent of Australia, and some are bold enough to assert that it is the longest distance ever spoken over on any land lines the world over. Perhaps some of the ENGINEER'S readers can say whether this is so or not.

MELBOURNE, AUSTRALIA.

THE DENAYROUSE ELECTRIC GAS BURNER.

QUITE a sensation was created a week or two ago by Professor Vivian Lewes informing the members of the Gas Institute at Edinburgh that a French scientist, M. Denayrouse, had discovered a means of increasing the illuminating power of gas something like fifteen times. Prof. Lewes had been made aware of the discovery during a visit to M. Denayrouse in Paris, and he had obtained permission to experiment with the new method of gas lighting and to make a communication upon the subject to the Edinburgh meeting.

In this invention M. Denayrouse had first been struck with the idea of applying the principle of the blow-pipe to the gas burner. He employs a lamp with a spherical shaped metallic body, and an incandescent mantle. In the body of the lamp is placed a very small dynamo working a ventilator and receiving the current from a couple of small accumulators. The electrical energy required is exceedingly small, and is said to be only about 1-8 volt and

1-10 ampere. This, however, is quite sufficient to force a current of air up through the mantle and to cause the gas to burn with remarkable brilliancy.

According to M. Mellet, the lamp has a density of 35 to 40 carcels, and consumes 7 litres of gas per carcel. Prof. Lewes had, however, been shown a lamp of 80 carcels (about 800 C. P.), and he was convinced that the light was quite as brilliant as an arc lamp.

LITERATURE.

The Telephone Systems of the Continent of Europe. By A. R. Bennett, M. I. E. E. Longmans, Green & Co., London and New York: 1895. pp. XIV., 436, with 169 illustrations. Crown 8vo., price $4.50.

This book is an interesting addition to the literature of telephony, of which, exception being made of Prescott's "Electric Telephone," it forms so far the most imposing volume. It is a book with a history and a book with a purpose, and it is heavily weighted with a bias that the trained telephone man may be trusted to discover for himself. But as there are springing up in this country many telephone men who have yet their training to get, it may be worth while to supply a coefficient of correction with which to establish a fair standard of comparison in the study of Mr. Bennett's racy pages. The avowed object pursued by Mr. Bennett in describing those features of telephony in Continental Europe to which he has devoted his attention is to convince the inhabitants of Great Britain that they pay too much for their telephone service; that that service is generally inferior in point of facilities rendered to the service enjoyed by Austrians, Germans, Frenchmen, Swiss, Swedes, Norwegians and even Spaniards; and that the British Post Office Administration is hopelessly in the dark regarding its obligations to the British public in the telephonic line.

Mr. Bennett is a telephone man of long if somewhat narrow experience. From 1880 to 1890 he occupied, as set forth on his title page, various positions in the English provinces in different English and Scotch Telephone companies, his longest term of service being spent as "General Manager and Chief Engineer in Scotland and the Northwest of England to the National Telephone Company." Shortly after the amalgamation of all the English telephone companies with the National Co., Mr. Bennett became identified with the movement, consequent to the expiry of the British Bell patent, to start telephone exchanges in opposition to those of the National—a movement that began and ended with the establishment of the Mutual Telephone Company at Manchester. Since that time Mr. Bennett has been a consistent and persistent advocate of low telephone rates in England. In 1892 he was general manager and engineer to the New Telephone Company, which proposed to "telephone" London, on a method that flatly disregarded the experience of every large telephone system in the world, at a flat rate of $40. The New Company, fortunately for its shareholders, never went into action as it was taken over by the National while still on the stocks—doubtless on the principle that it was better to purchase an unfinished hull than a wreck. It has been hinted that not all the promoters of the New Company were keenly disappointed that the novelty of the undertaking never got a chance to wear off, but to give Mr. Bennett his due he was not one of these, for he has eminently the courage of his opinions—to such a degree indeed that, as often happens, his courage frequently obscures his vision, as we shall presently show.

The New Company being left in a position to be only new and nothing more, and the management of the Mutual exchange at Manchester (which was sold to the New before the New was sold to the National) not being field enough for Mr. Bennett's abundant energies he has devoted himself for some time past to the task of persuading British municipalities that telephone systems could cheaply, profitably and usefully come within their ever enlarging sphere of influence. His Continental tour and the preparation of the book in which its record is set forth were undertaken in order to provide the municipal authorities and other possible exploiters of telephone systems with impressions seen through Mr. Bennett's rose colored glasses of the cheapness and abundance of telephone facilities on the Continent. We say rose colored because Mr. Bennett makes everything bear in favor of his own contentions that similar cheapness and abundance are British rights; but we think that a pair of green glasses must also have been among Mr. Bennett's traveling equipment, so obvious is the innocence of many of his conclusions and inferences.

So much for the history and the purpose of the book. Now for the execution. Besides an introduction covering 31 pages, there are twenty-six chapters, one for each European country or State, the only omission being the Republic of Andorra. The longest chapters are devoted to Sweden, where there was much to describe, and to Germany, with whose telephone officials Mr. Bennett had a bone to pick, an operation which he performs with characteristically Scotch delight in the operation. These two countries take up about a fifth of the book, while there are several chapters—relating to Bosnia-Herzogovina, Greece, Servia, Montenegro and Turkey—closely resembling the famous one on snakes in Ireland. Most of the chapters are divided systematically into sections as follows: History and Present Position; Service Rendered to the Public; Tariffs; Way-Leaves; Switching Arrangements; Hours of Service; Subscriber's Instruments; Outside Work (local); Outside Work (trunk); Payment of Workmen and Operators, and Statistics. All these subjects Mr. Bennett describes clearly and often in great detail, giving a quantity of valuable and interesting information on the actual status of telephone work on the Continent.

Before proceeding further let us say that as a guide for comparison of the rates in different countries and as an advocate for the application of the charges obtaining in one to the conditions obtaining in another Mr. Bennett is distinctly misleading. In all questions of rates and charges—and whether he loads his gun with a Dutch village or a Norwegian town or the long distance system of a country where there are no long distances, Mr. Bennett fires always at the rates and charges in Great Britain—the book is simply a piece of special pleading. Very well written special pleading no doubt, and probably well calculated to convince the average County Councillor or municipal official. But it would be just as easy for another telephone man, or for Mr. Bennett himself for that matter, to go over the same ground and, by bringing out many and various points that in the present work are ignored, to produce an equally elaborate piece of special pleading on the other side of the case, or better still an impartial description of the conditions that produce the results set forth.

One of the cardinal errors running through the book is the assumption that the purchasing power of money is the same in all countries. Although Mr. Bennett is comparing rates and charges in twenty-one different countries with those in Great Britain he sedulously converts at the closest rate of exchange every money figure into pounds, shillings and pence, down to two decimals of a penny, without offering a word of light on the difference in the cost of living—in the purchasing power of money. It is like supplying a lot of working drawings without scale or measurements. The reader is left to imagine that a pound sterling is the same thing in Sweden, Norway, Belgium, Switzerland, and so on, as it is in Great Britain. Nothing could be more erroneous. The average Swede, Norwegian, Belgian, German or Swiss looks with more respect on a sum equal to a couple of dollars than the average Englishman does on a sovereign, and does about as well with it in purchasing the necessaries of life.

By way of exaggerating this error, which underlies all that is contained in the book bearing on charges, Mr. Bennett ignores, or at any rate fails to give due weight to wide differences in the conditions under which telephone work is done; and he further assumes that all the rates he mentions are profitable. In some cases he even asserts as much in spite of contrary evidence afforded by official reports. The Swiss telephone system, for instance, he says pays, although the official report for 1893 shows a deficit and predicts a larger one for 1894. An impartial writer would scarcely have committed either of these errors and would not have allowed illustrations of extraordinary divergence of conditions and distinctly unprofitable charges to pass through his hands without explanation or comment.

The American reader who studies Mr. Bennett with any idea of posting himself on the main doctrine of the author—the rate question—will be at even a greater disadvantage than his English cousin. It requires no little mental effort, even for one having fair experience in the spending both of pounds, shillings and pence and of dollars and cents, to reduce such sums as £5 11s. 1d., or £9. 14s. 2½d. to anything approaching the equivalent amount in United States currency; and as for amounts like 1.92d, 1.99d, and .096d, most Americans will wonder why people should bother about asking anything at all rather than deal with such decimated charges, though they will marvel at the cheapness of the countries where such prices obtain. Mr. Bennett would have done all his readers a service had he put the rates in the native currencies as well as in sterling. By doing so he would have given a better idea of the real charges—for the unit of money is a moderately good index of its purchasing power—and he would have given Americans a chance, the conversion of francs, florins, marks and even kronor into dollars and cents being simple work. As it is, they will have to read with the assistance of a banker's sterling exchange clerk.

In his introduction Mr. Bennett delivers a broadside to the National Telephone Company and to the British Post Office Administration, and he follows this up with a scattering volley of flings and taunts all through the rest of the book. Indeed, so bitter is Mr. Bennett's invective and so splenetic his comparisons of everything continental with the corresponding British arrangement, or the lack of it, that one is led to imagine the prompting of some motive less disinterested than the abstract desire to see his countrymen revel in the advantages of cheap and abundant telephony. Whatever Mr. Bennett's particular grievance may be it is a pity that he should have let it obtrude itself so obviously and persistently, as the reiterated carping and nagging at British

telephone men and methods are apt to both irritate the reader and cause him to discount the observations and impressions set forth. The gist of the introductory diatribe is that the National Telephone Company is a dropsical monopolist and the Post Office an ostrich-like obstructionist. At the National Company is freely hurled the familiar cry of "water" which every large corporation has to hear, and hears with complacency because no large industry was ever built up on the foundation of a new invention without various unproductive expenditures that the envious and socialistic always class together as "water." The curious thing is that the people who talk most about "water" almost always propose Government or municipal management as the remedy, ignoring that government and municipal administrations are as a general thing the most abominably watered and the worst managed institutions in the world. The policy of the British Post Office towards the telephone has been much that of all the European Governments, vacillating and unpractical. This attitude is the result partly of the Government monopoly of the telegraphs that obtains in every European country and partly of the strange incapacity that Government officials universally show for adopting common sense methods in dealing with new inventions of a commercial nature. If the telephone had been a Maxim gun or a dirigible balloon the Governments of Europe would have tumbled over each others' moneybags in the scramble for it. But being only the foundation of an industry of wide commercial importance they all turned the cold shoulder to it, snubbed it and repressed it. When private corporations (watered of course) showed them what could be done with it they took it up in the usual governmental and thoroughly uncommercial way.

However, with Mr. Bennett's quarrels with the National Company and with the British Post Office the present reviewer has no concern except to point out that the bitterness and aggressiveness with which he conducts them tempers his judgment and weighs down his impressions and conclusions with a strong bias. We should perhaps be falling into almost as great an exaggeration as Mr. Bennett himself is guilty of when he says that the capital of the National Company is three parts water to one part money invested in plant were we to say that the book is one part facts to three parts of a solvent composed of bias, suppression and exaggeration. However, if this review could be as long as the book itself perhaps this qualification might be completely substantiated. In the present case all that the reader can be advised to do is to read the facts and draw his own conclusions as to how the results are arrived at and what the rates set forth really mean by the standard of values of the various countries. In this he gets little assistance from Mr. Bennett except in one or two cases where actual figures of expenses and earnings are published; and from these it is easy to see, by analyzing the figures for salaries, rents, wayleaves and a few other items, that kronor or florins in their native land cut a very different figure from kronor or florins translated into sterling or dollars and considered by the standard of values in the countries where pounds and dollars most freely circulate.

However, the book fortunately contains much interesting matter and many facts besides the enumeration of rates and charges. The descriptions and illustrations of overhead line construction in several Continental countries especially will be something of a revelation to many American telephone managers and engineers who have not yet or have but quite recently got beyond the wooden age. At much of the switchboard and underground work described they will smile—when they do not weep—but the neat, strong, sightly and often highly ornamental iron crossarms and poles, distributing towers and roof fixtures that Mr. Bennett made note of in Holland, Belgium, Switzerland and other countries they cannot fail to admire. Similar practice here would have avoided much of the discredit that has attached to American overhead line construction.

While there are a great many points of difference brought out in the details of the telephone service of the different countries as described by Mr. Bennett, a careful perusal of the book shows a strong family resemblance among them all. In all but a very few places the lines are entirely overhead and constructed with bronze wire, generally of 1.25 mm. (.049 in.) diameter; the switchboard plant, with rare exceptions, is of a type definitely abandoned in America six or seven years ago and in some cases even more antique; while metallic circuits exist on a large scale in only two systems, Paris and Stockholm. The underground work, where special telephone underground construction has been executed, is peculiar. In Paris and Lyons the sewers accommodate the cables; in Vienna gutta percha cables buried solid in wooden troughs are used; in Germany and Switzerland the conduits are iron pipes of large diameter in which a number of cables are drawn in, one on top of the others; practically in Sweden alone has good engineering been done in the underground line, the conduits being of cement with a separate duct for each cable. In Stuttgart there has been put down a small amount of a peculiar style of conduit—a sort of compromise between the large iron pipes of Prussia, Bavaria and Switzerland and the single cable ducts of Sweden and America—formed of inverted cement troughs laid one on top of another, several cables lying side by side as on a shelf.

The only up-to-date switchboards seem to be at Zurich, which has a Western Electric bridging board with self-restoring drops, and at one office in Stockholm equipped with a Swedish adaptation of the same type of board.

The fine points in telephone practice and operation as understood in this country seem to be very generally absent; every variety of eccentricity is shown in the operating methods, the aggregate result being to throw more work and responsibility and to impose many more restrictions on the subscriber than is usual here. This is especially noticeable in the long distance service or, rather, interurban service, for in few of the countries treated of do long distances properly speaking exist. The long distance service is invariably conducted by the Government at non-paying rates, which to a great extent accounts for the many conditions and restrictions and the general inadequacy of the facilities.

In regard to the services rendered to the public there is wide divergence to be noted. In quite a number of important places no night service is given; all exchanges in the German Empire, even Berlin with 29,000 subscribers, are closed at 10 P. M., and several other countries carry out the same practice. In Switzerland, on the other hand, any exchange of over 200 lines has permanent service, and permanent service is the rule in the larger exchanges in Austria, Belgium, Denmark, France, Norway and Sweden. In most of the countries the facility of telephoning telegrams between the subscribers' stations and the telegraph office exists, in some cases without charge, in others subject to a small charge on each telegram, and in still others in consideration of an annual subscription. Mr. Bennett makes a great deal out of what are called on the continent "phonogrammes"—messages telephoned to the central office, written out and delivered like telegrams. This service exists in several countries and although Mr. Bennett almost goes into hysterics over its convenience, beauty and cheapness, he does not stop to point out the very limited application it can have and the slight use actually made of it. In Switzerland, for instance, there were in 1893 about 6,500 "phonogrammes" for nearly 17,000 stations or a trifle over a third of a message per subscriber in the whole year; as evidence of the extraordinary avidity of the general public to use this service there were in the same year just 19 "phonogrammes" sent from public stations in Switzerland!

The long distance service of most of the countries is obviously operated according to the uncommercial policy of Government administrations. The general rule is a single charge for any distance, although charges are graded according to distance in France, Austria, Sweden, Switzerland and one or two other places. How the flat charge without regard to distance works out is shown by Mr. Bennett's own figures, from which it appears that the average earnings per mile of wire of the Belgian long distance lines for 1893 was 31.60 fr. (say $6.32) or as Mr. Bennett would say, £1, 5 s., 3½d—not much more, at English rates, than the cost of maintenance of the wire. If the circuits were long there might be a profit in this, considering what 31.60 fr. represent in Belgium, but the average length of the 75 Belgium trunk lines is only about 40 miles, so the ratio of operating expense to line maintenance is very high. In Switzerland the earnings per mile of wire are about double the Belgian figure, but the average length of the Swiss interurban circuits is only 15 miles, giving a still greater ratio of operating expense to line maintenance.

To sum up, Mr. Bennett's book leaves us with the impression that the telephone systems of the Continent of Europe are generally behind the times as regards line exchange and instrument equipment and quality of service rendered to the public; the only conspicuous exception is Sweden where special causes and circumstances have brought about a special state of affairs. Taking the rates specified in connection with the various conditions of wonderfully cheap labor, supervision, rents, wayleaves and materials, the obsolete and inferior equipment and methods of operating and the frequent occurence of Government administration without regard to commercial considerations, nothing very startling in the way of cheapness is shown.

As a piece of book making the work is well done. Mr. Bennett shows no small amount of literary skill and polish and although it is not his policy to criticize he occasionally becomes mildly humorous at the expense of some of the telephonic eccentricities he encountered; in Prussia alone, however, did he give his critical and humorous powers full play. The illustrations and diagrams are as a rule clear and well executed and form an admirable accompaniment to the text. Almost the only exception is the diagram of the Swedish self-restoring drop (p. 347) which is nearly unintelligible and makes a strange contrast with the clear drawing of the Western Electric self-restoring drop on page 391. The book is thoroughly well printed on good paper, singularly free from typographical errors, and actually bound so that opened flat it will stay open without promptly finding a new place for itself.

W. H.

NIAGARA FALLS real estate appears to be active in these days. The parties who recently bought so largely at Depew have now secured control of about 3000 acres at La Salle.

NOTES ON THE RECONSTRUCTION OF A SMALL CENTRAL STATION PLANT.[1]

BY FRANKLIN L. POPE.

THE financial condition of the smaller central station electric lighting plants throughout the country is at the present time by no means satisfactory, and in too many instances cannot even be truthfully said to be encouraging. A survey of the field shows that very few such plants located in towns having less than 10,000 inhabitants are earning more money than is necessary to meet their operating expenses and to provide for indispensable current repairs. In the state of Massachusetts, in which the operations of all electric lighting companies are by law made a matter of public record, it appears from the latest reports that the aggregate liabilities of the fifty-seven companies operating in that state, including stocks, bonds, and floating indebtedness, amounted on June 30, 1894, in round numbers to $14,000,000, nearly all of which stands charged to construction account. The net earnings for the preceding year were $1,000,000, or about 7.1 per cent. on the total investment: a sum obviously quite insufficient to provide for depreciation and at the same time pay a fair dividend on the capital which has gone into the business. But if half a dozen of the larger plants, in cities like Boston, Lowell, Worcester, Springfield, Lynn and Fall River were excluded from the list, the showing for the smaller plants would be even far worse than it now appears.

Many of these small plants were started at an earlier day than could have been justified by any reasonable estimate of the business then in sight, and now find themselves hampered by inconvenient buildings, and with unsuitable machinery bought at high prices, and encumbered with defective business methods which experience has shown to be wholly inconsistent with the dictates of good judgment.

Having been called upon during the past year to advise the owners of an old plant in reference to certain changes which had been suggested as desirable, and having afterwards been employed in a professional capacity to design the work and superintend its execution, I have thought that some account of what we undertook to do and how we did it, might not be without interest to the members of the Institute.

The Great Barrington (Mass.) Electric Light Company was organized and commenced business in 1888. The population of the district intended to be served was about 3,000, and most of the expected consumers were located within 2,000 feet of the point decided upon for the station. This was built of wood in the most inexpensive manner possible, and was placed alongside the railroad for convenience in receiving coal, although at the same time the danger from fire was materially increased. The original outfit was an Edison 3-wire, equipped with a pair of 250-light 110-volt dynamos, and the company commenced business with 281 lights on contract at $10 per year each, wiring free. The center of distribution was 1,800 feet from the station, necessitating over a ton of copper in the feeders alone. Generally speaking, the plant was well laid out, and well built as things went in those days. The two dynamos were belted to a single 80 H. P. Armington & Sims engine. The original cost of the plant was about $16,000. The following year a Schuyler arc-plant for street-lighting was added, carrying 35 arcs, nominally of 1,500 C. P., which was run from the same engine and boiler. In 1890, the plant was considerably enlarged by the addition of a second arc machine, a Westinghouse 500-light alternator, and a second engine and boiler of the same capacity as the first. An 80 K. W. Westinghouse dynamo of more modern type was afterwards substituted for the original one.

Upon examining the plant last year, I found the Edison machines carrying on Saturday evenings a maximum load of some 450 lights, while three evenings in the week (with the stores closed) it fell to perhaps half that amount. The two Schuyler machines, with an aggregate capacity of 55 to 60 lights were carrying about 38 to 40 or an equivalent of that amount, while the Westinghouse machine was seldom as much as half-loaded, carrying a maximum of possibly 500 lights during three or four months of the summer season, and not much more than one-fourth that amount the remainder of the year. Necessarily, with so many dynamos of different types, and with such a variable, yet small, average output, the consumption of coal was excessive as compared with the light delivered and paid for.

The street lines, according to the usual practice, were of No. 6 B. & S. weather-proof wire; the poles were of cedar, of good size and fitted with pine or spruce cross-arms, with common green glass insulators set upon wooden pins. In consequence of a silly prejudice, which had been fomented amongst the citizens by interested parties against permitting poles to be set in the streets, the wires, in a very great number of instances, had been attached, by cross-arms or brackets, to the trunks of the immense elm trees with which the streets of the town were shaded; a practice which occasioned an enormous loss of current every wet night as well as much irregularity in the performance of the lights. The effect on the trees was by no means salutary, while the appearance was as much worse than that of poles in the streets as could possibly be imagined.

The village of Great Barrington extends for the most part along a single broad thoroughfare for a distance of nearly three miles, and the street-lighting circuits are consequently very straggling. The 1,500 C. P. lamps, which were suspended at intervals of 800 to 1,000 feet, were actually of very little service in illuminating the densely shaded streets.

After a careful consideration of the situation, keeping in view the greatest possible reduction of present and future operating expenses, it was determined the wisest course to pursue would be to consolidate the whole service so that it could be supplied by one dynamo, in place of five underloaded ones. In pursuance of this plan it was decided to adopt the two-phase alternating system, at a maximum pressure of 2,100 volts in the primaries, and 105 volts in the secondaries, with a frequency sufficiently low to permit the advantageous use of induction motors if required. It was furthermore decided to abandon the steam plant, and to make arrangements to utilize some one of the excellent water-powers which were available within practicable distances. Under ordinary circumstances, I should have hesitated to recommend the substitution of water-power for steam as the sole source of power for the operation of an electric lighting plant. Water-power is an invaluable auxiliary, and when conveniently available for use in conjunction with steam, may often be made to save a very large coal bill in the course of a year.

In the present instance, the choice of a water-privilege finally reduced itself to two sites, one in the town itself, within half a mile of the centre of consumption, and the other at Glendale village, seven miles distant, both situated on the Housatonic river.

While negotiations were still pending with the owners of the Glendale privilege and also the one in the village already referred to, overtures were received from a manufacturing company owning a third exceptionally desirable privilege, on the same stream, at an intermediate point considerably nearer than Glendale. This company had only recently completed a new dam, head-gates, raceways, etc., at a very considerable expense, and was willing to lease the complete establishment, including a new McCormick turbine of 325 H. P. and a two-phase Stanley generator of corresponding capacity, at a monthly rental, based upon the actual output as measured in kilowatt hours at the dynamo terminals, provided that a certain minimum monthly consumption was guaranteed. With the same volume of water as at Glendale, the fall at this point was 20 feet, assuring at least 417 H. P. at lowest water, during lighting hours. All the hydraulic apparatus and appointments were of the best possible construction, and well-calculated to ensure absolute permanency of operation.

The minimum rental required was somewhat less than the amount of the coal-bill of the Great Barrington company for the preceding fiscal year, but while the immediate saving in operating expenses was not large, the acceptance of the proposition would place the company in a position to reduce its rates to consumers, for the reason that its output might be very largely increased without materially augmenting its operating expenses. A lease for a term of years was accordingly closed.

In laying out the plant it was determined to bring the main feeders directly to a distributing station in the village, to be used principally as a convenient headquarters for testing the circuits and controlling the street-lighting service. In laying out the transmission line, a surveyor was employed, and a preliminary line was run directly from the power-house to the distributing station. The air-line distance was found to be 5.15 miles. With the assistance of the surveyor, the actual line was then staked out, going directly across country, and keeping as near as circumstances permitted to the transit line. About half the distance, the transit-line was found to so nearly coincide with existing highways, that the consent of the local authorities was obtained to set the poles along the highway location; the remainder of the route lay principally through uncultivated land of little value, so that a comparatively small expenditure was sufficient to secure a release from all claims for land-damages. This enabled the line to be located with long stretches absolutely straight, avoiding all sharp angles; a very important consideration when heavy wires are used. The poles were of selected chestnut with natural butts, usually set five feet in the ground at maximum intervals of 125 feet. The poles were ordinarily 25 feet long and 8 inches thick at the small end. Shorter poles were sometimes used on elevations and longer ones in depressions, in order to equalize the strain as much as possible. The insulators used were of the large double-bell white porcelain type (German government standard), and were imported by us from Berlin. The insulator of the top wire is set upon a malleable iron stem 14 inches long screwed into the top of the pole which is tapered to 5 inches diameter and protected from splitting by driving on a wrought-iron ring. The tapered part of the pole, as well as the top, was given a coating of mineral paint mixed as thick as it could be spread with a brush. The insulator of the second wire is carried on a malleable iron gooseneck, screwed into a 5/8 inch hole bored in the side of the pole, in such position as to bring the wires about 16 inches apart.

1. Abstract of a paper read before the Amer. Inst. Elec. Engs., Niagara Falls, June 26-30, 1895.

Another hole was bored on the opposite side of the pole, intended to take the goose-neck of the third wire at some future time, leaving the same interval between the second and third wires. The porcelain insulators are fixed to their iron supports by a packing of oakum placed between the screw-threads, which serves to prevent any danger of breakage by expansion or contraction. The line-wire is laid in a groove formed in the top of the insulator, except upon the curves and angles, in which case it is tied at the side in a circumferential groove, as is usual in this country.

The German method of tying is quite complex, and unnecessarily strong; in case of undue strain, if anything gives way it had best be the tie wire. We therefore devised a simple tie which was easily and quickly applied, and which has so far served an admirable purpose. We were obliged to string the wires during very cold weather; sometimes as cold as 8 or 10 degrees below zero, and hence it was necessary to strain them very tight. A block and fall and a well-trained horse were used in pulling up, usually six or seven spans of one wire at a time. The hook of the block was always attached to the copper wire, whether bare or insulated, with a chain-knot made of ⅜ inch rope. The feeder-wires were of No. 8 B. & S. soft copper, covered with weather-proof "insulation" along the highway (as a concession to enlightened public opinion), but elsewhere bare. The lengths of wire were joined with McIntire twisted couplings; the unusual strain we had to put upon them occasionally pulled one apart, and this led us, out of abundant caution, to solder them, although this was done for mechanical rather than for electrical reasons. Only two feeder wires have as yet been strung, providing for a single-phase current from one side of the two-phase generator, but it is the intention to run a third feeder hereafter, which will enable two-phase induction motors to be connected to the same distributing system.

A pair of telephone wires of No. 12 steel were strung below the feeder-wires, and these were supported upon small German porcelain insulators on iron goose-necks on opposite sides of the poles. These wires were transposed at intervals of about a mile, in order to eliminate the inductive effects of the alternating current in the feeders. The insulation of the circuit even in the worst of weather is simply faultless.[1]

The system has been planned to deliver the current at the distributing station at a uniform pressure of 2,100 volts. Two distributing centres were fixed upon in the old Edison 3-wire network, and at each of these points a pair of large transformers, having a ratio of 20 : 1, were fixed upon a pole, with their respective primaries in series between a pair of branch feeders from the distributing system, and their secondaries were coupled in series in like manner with the neutral wire between them. None of the consumers on the old Edison system knew when the change had been made to the new service from anything they were able to notice in the behavior of the lights.

The next thing done was to reconstruct the street-lighting system. In place of the 36 arcs of 1500 nominal C. P. formerly in use we substituted 126 incandescent lamps of 50 volts and 32 C. P., placed in Iona fixtures projecting horizontally from the poles 14 feet above the ground. The lights, as a rule, were fixed upon every alternate pole, but in the business centre, the street being broad, they were placed on each side at intervals of about 250 feet, and staggered, so as not to come opposite each other. A Shallenberger shunt cut-out was applied to each lamp. The usual number of lamps in each circuit was 42, although we have since placed, in some cases, as many as 47 in one series without reducing the brilliancy of illumination sufficiently to be noticeable by any one but an expert. One end of each street-lighting circuit is joined to a special feeder leading to the sub-station, where it is connected with the main feeder through a knife-switch. The other end of each lamp-circuit is connected to any conveniently located branch feeder of the regular commercial lighting service. Each lamp-circuit has, or will have, a fuse-block and cut-out enclosed in a weather-proof box at each end, where it joins the opposite feeders. These 32 C. P. lamps, when run at full candle-power, furnish a most satisfactory illumination and give the streets a very attractive appearance. So far as possible each lamp was located with the aid of a transit and level, so as to get them in absolutely straight lines both vertically and horizontally, a precaution which adds materially to the decorative effect.

1 I regret that I am unable to present any actual measurements of the insulation of the line of the Great Barrington company, no opportunity having occurred since the work was completed, of making tests under atmospheric conditions of minimum insulation. Several years ago, however, while engaged in telegraphic service, I made a series of nearly 100 separate tests in rainy and foggy weather, extending over a period of five years, of a set of 10 porcelain insulators of the same make and pattern in every particular as those now on the Great Barrington line, erected on a house-top in the city and therefore much exposed to smoke and dirt. These measurements gave a mean resistance of 28.3 megohms. and a minimum resistance of 19 megohms per insulator. On a metallic circuit therefore, the minimum insulation resistance at each pole would be 38 megohms. On the Great Barrington line of 28,260 feet there are 250 poles and other supports, and hence we may assume that the minimum resistance of the insulation of the circuit as a whole would be 152,000 ohms. The current loss by leakage is found by dividing the mean voltage by the insulation resistance; $\frac{2,200}{152,000} = 0.014$ ampere; an amount too small for serious consideration.

It is admitted by all that the streets of the town are much more satisfactorily lighted by the incandescents than they formerly were by the arc lamps, while the actual cost to the company is considerably less. The new lamps were cut in, one at a time on the old arc wires, jumpers being temporarily placed across the terminals until everything was in readiness to discontine the use of arc machines.

One of the most marked advantages of the series street-lighting system, especially when shunt cut-outs are used, is its great flexibility and convenience. For example, instead of placing from 40 to 45 50-volt lamps in one series, we may use 20 to 23 100-volt lamps, or if an odd number be required, less than is necessary to make up a circuit, the deficit may be supplied by adding extra shunt-boxes in series at any convenient point in the circuit, until the pressure has been reduced to the required point. From time to time, as new lights are added, these spare shunt-boxes are one after another brought into use in connection with them. Sometimes, also, we temporarily install extra street-lights by connecting them in parallel to the secondary mains of the regular commercial service, ultimately transferring them to new series circuits.

It has been found to be desirable to use a lamp of rather low efficiency for the street-lighting service, as there is always danger of leakage and short circuits from wet boughs of trees and other objects getting into contact with the wires, and thus diverting an abnormal current through some portion of a lamp circuit. In such case, a lamp of high efficiency is pretty certain to be burned out, or at least to have its career of usefulness materially abridged. In this plant, the average consumption of energy in the street-lights, including lamps, lines, shunts, and leakage is found to be about 140 watts per lamp of 32 C. P.

Perhaps the most ticklish part of the whole undertaking was the changing over of the Westinghouse system, which was a 1050-volt primary and a 52-volt secondary, running at 16,500 alternations. In accordance with the new plan, it was of course necessary to double the pressure both in the primary and secondary circuits, and to substitute 104-volt for 52-volt lamps throughout. A preliminary test of one of the transformers demonstrated, that which perhaps might have been foreseen from theoretical considerations, viz.: that a dangerous quantity of heat was developed within a few hours when it was used to convert from 2,000 volts down to 100. In order to utilize, so far as possible, the old transformers, and at the same time avoid the above difficulty, various expedients were resorted to. Wherever a group of consumers was located in one neighborhood, a pair of large transformers was installed, with secondary mains extending from 500 to 600 feet in various directions; these transformers being of course placed in series with each other. Scattering consumers as far as practicable, were connected together in small groups, and supplied by a pair of small transformers coupled in the same way. The Westinghouse meters, having been originally constructed for a frequency of 16,500 alternations, ran slow when the frequency was reduced to 8,000. The necessary coefficient for correction of the readings was easily ascertained by experiment, and as fast as possible the meters were fitted with new disks, supplied by the Westinghouse company at a trifling expense, and adapted to the lower frequency.

Of course it will be understood that the reason for resorting to these various shifts and expedients, was merely that we might utililize the old apparatus as far as it could possibly be done, and also that we might carry on the work of reconstruction, for the most part, with the ordinary working force of the establishment.

The following figures are selected from a much larger number obtained by actual measurement of the performance, of the McCormick horizontal double turbine in the testing-flume of the Holyoke Water-power Company.

Head acting on Wheel feet.	Revolutions per minute.	Quantity of water passing through Wheel (cu. ft. per sec.)	Horse-Power.	Per cent. of Efficiency.
16.66	156 25	81.75	124.50	80.99
16.80	155.00	70 79	109.37	81.18
17.02	154.50	63.42	95.86	78 89
17.26	156.75	52.19	73.42	71.95
17.44	152.25	42.55	53.71	63.90

These results are worthy of particular note, for the reason that they show a very high percentage of efficiency maintained through a wide range of variation in the quantity of water passing through the wheel; a most valuable characteristic for electric work.

The turbine carries upon its shaft, a driving-pulley 100 inches in diameter, weighing 11,000 lbs. which serves as a balance-wheel. It is also provided with a Replogle electric governor operated by three cells of gravity battery, which has never failed to do its work quickly and certainly, even under trying conditions.

In carrying out this work, some things have been learned by

experience which may be of use to others called upon to advise or to undertake the construction of similar works, and I will therefore venture to summarize some of my conclusions as follows:

1. In considering the advisability of operating an electric plant by water-power do not on any account, neglect to ascertain from authentic sources of information, just how much water can be depended upon during the low stage in an extra dry year, *for this is the measure of its value for electric work* except when used as an auxiliary to steam. The ordinary estimates of the commercial value of a water-power are only too apt to prove preposterous exaggerations.

2. If rights-of-way or releases of damages can be obtained without too much trouble and expense, it is better to build the feeder line as directly across country as may be, than to follow a highway. The saving in cost of construction will usually be more than enough to pay for the right-of-way, and on such a route there need be no interference from trees, while many inconvenient angles and much trouble in guying and bracing are avoided. Shorter and stouter poles may also be used; in itself a very important consideration.

3. In electric line-construction it is preferable to dispense with cross-arms unless there are more than six wires. The best arrangement is to place one wire on a top pin and the others alternately on the front and back of the pole, at a vertical distance apart of 12 inches. This construction not only costs less than properly braced cross-arms, but is much less conspicuous and therefore much less objectionable in a public street; is less interfered with by trees; and is far more durable. Much trouble is caused by the decay of cross-arms after they have been exposed a few years to the weather; they split at the ends so that the pins come out, and not infrequently break in the middle, thus fouling the wires.

4. In medium-sized towns and cities, especially in shaded streets, the incandescent lamp may be made to give a far better distribution of light for the same money than is possible with the "half-arcs" so extensively used, and is much less troublesome to maintain in good working order. My own experience leads me to think that the lamps ought not to be of less than 24 or more than 32 candle-power. Use lamps of low rather than high efficiency, but run them at full candle-power, or even a trifle above. Good street lights, well arranged, and renewed sufficiently often, are the best possible advertisement for any electric company.

5. Use large transformers as far as practicable, placing the consumers within 500 or 600 feet radius upon secondary mains. We have used both two-wire and three-wire mains. The latter plan is certainly to be recommended when the distance approximates or exceeds 500 feet, but for short distances, as for example, when distributing within a single block at a pressure of 100 volts or more, it is a question whether the gain in cost of copper over the two-wire plan is of sufficient importance to offset the additional complexity.

6. It was found that raising the voltage in the residence district from 1,000 : 50 to 2,000 : 100 greatly improved the uniformity of distribution by lessening the potential drop without entailing any corresponding disadvantages. It would seem to be preferable, on every account, to use the higher pressure.

7. One of the most important minor points in the management of a plant is apt to be too much neglected; the maintenance of the insulation of the wires by promptly replacing all cracked and broken insulators, and by keeping the wires absolutely free from contact with uninsulated objects. The covered wires which lead into the hoods of the street-lamps need to be carefully looked after.

8. Number all the poles with yellow plant applied with a stencil on a black ground; and keep a record book, of the position of each one and its distance by the line from the test-station.

9. In selecting a turbine wheel, consult competent authorities as to the available fall and minimum quantity of water, and when making the purchase do not expect to get a thousand dollar wheel for a hundred dollars. Pay a fair price and insist, not only that the wheel shall be well made in every way, but that it shall be tested by an expert before acceptance. If it does not give an average efficiency of 76 per cent. between half-gate and full-gate, it is not advisable to accept it, inasmuch as you can easily do better, as our own experience proves.

10 I think our experience shows that it is possible to largely increase the net earnings of an old plant without necessarily re-fitting it throughout, but plenty of time should be taken for consideration as well as for execution, in order to secure satisfactory results with a moderate expenditure.

"BUFFALO BLINDNESS."

Had the City of Buffalo been like Chicago, says the Chicago *Herald*, it would have promptly contracted with the Niagara company for the entire output of electrical power, thus making it possible for Buffalo to become one of the chief manufacturing centres on the continent. As it is, the new town of Depew and other points contiguous to the falls are about to witness a marvelous development of new industries in the utilization of the new power.

LETTERS TO THE EDITOR.

THE REAL REASON FOR CONSTANT POTENTIAL ARCS.

In your issue of the 12th of June, 1895, is a short article on "The Rushmore Arc Lamp for Constant Potential Circuits." In it several general statements are made which are in a measure misleading and which it would seem well to correct. In the first place, the general adoption of "the incandescent arc lamp" or arc lamp operating on a constant potential circuit is not due to the greater economy of the constant potential over the constant current system as there stated. So far as the question of economy is concerned, the constant current system is far the most economical whether looked at from the point of view of a complete electrical installation or from that of the amount of energy consumed by the lamps in producing a given amount of light. On the constant current system, the cost of a complete installation for a given number of arc lamps distributed over a given area is much less than for a corresponding number of similar lamps operated on the constant potential system. This statement is patent and goes without saying. So far as the economy in the operation of the lamps is concerned, the direct arc lamp is the most economical for a given amount of light, on account of the great amount of power which has to be wasted in the dead resistance which has to be used with the lamps when operated on a constant potential circuit. Taking the lamps alone and operating them at 45 volts and 7 amperes each, the direct arc lamp would consume 315 watts. The constant potential arc operated upon a 110 volt circuit necessitates two lamps being run in series with an additional dead resistance to cut down the excess of voltage. The total watts consumed under the above conditions is 770 watts for each pair of lamps and rheostat or 630 watts for the lamps and 140 watts waste in the rheostat or 385 watts per lamp, so that so far as economy goes the economy is in favor of the direct current lamp system. The real reason for the general adoption of the arc lamp on constant potential circuits is the fact that either incandescent or arc lamps can be run indiscriminately on the constant potential circuit, thus approximating to the ideal system of distribution, which is of such a character that any form of translating device for light, heat or power may each as an independent unit, be operated upon it. In the second place, it does not follow that because the direct current lamp operates with the cheapest grades of carbons that it gives a satisfactory light as compared with the light given by an arc lamp operating on a constant potential circuit and burning a high grade carbon, nor is it a fact that the constant current arc lamps will keep their adjustment any better than the constant potential arc lamps. The arc lamp running on a constant potential circuit with cheap carbons, will give fully as satisfactory a light, so far as economy and steadiness of operation goes, as the constant current lamp, but this is not satisfactory enough for the purposes for which it is used, so its light giving qualities have been improved and perfected by the use of high grade carbons. A point in the use of high grade carbons which seems to be generally overlooked, is the fact, that besides giving a much better and steadier light than the lower grade carbons, they will also burn nearly twice as long, size for size, as the low grade carbon and although they may cost twice as much, yet the result is nearly the same as regards cost of carbons with the added advantage of vastly increased steadiness of light. The same statement is true of the constant current arc lamp. By burning in them a high grade carbon, most, if not all of their present flickering and spluttering can be done away with and they can be made to run almost as steadily and quietly as the constant potential lamps. A good deal would appear to depend on what is considered a satisfactory light for the conditions under which it is to operate. So far as adjustment in arc lamps go, there are in existence a great many forms of arc lamps and a great variety of adjustments, but there appears to be no reason why, in a well constructed arc lamp, one should keep its adjustment any better than another because it is operated upon a constant current circuit rather than a constant potential circuit. In fact it is more likely to be the other way as arc lamps on constant current circuits are usually subjected to more hard usage than those on the constant potential circuits and as a consequence are more likely to get out of order. Again, as regards the statements that arc lamps operated upon the constant potential circuits are run with much shorter arcs and at less voltage, the implication that they cannot under present conditions be run with longer arcs and at a higher voltage is misleading. It is perfectly possible so to do, and as a matter of fact most of the successful constant potential arc lamps of the day do run at just about the voltage stated, viz. 40 to 45 volts.

There is considerable misapprehension in the public mind as to the conditions under which the constant current and constant potential arc lamps operate. The general impression appears to be that the conditions are so different that the lamps themselves are radically different in construction and operation. This is not so. It is perfectly possible for the same lamp to operate with equal success on either the constant current or the constant potential circuit. The only difference lies in the required safety devices needed to suit the conditions of each circuit, but which

have nothing to do with the operation of the lamp mechanism proper, which may be identically the same in both.

There also appears to be a prevailing belief that the amount of light given by an arc lamp is directly in ratio with the number of watts consumed by the arc. This is not necessarily so. The amount of light depends on the amount of luminous heat generated by the current due to the resistance of the arc and carbons to the passage of the current. The amount of luminosity depends upon the mass of carbon to be heated up at the arc. It is quite possible to have this so large that very little light is obtained although the watts consumed may be the same as in another lamp, working with the same current but which is giving a better light due to the mass of carbon to be heated to luminosity being much less and in proper proportion to give a maximum amount of light for the amount of current used. It is perfectly possible for a lamp using a weaker current than another to give more light than the other, due to this same fact, and one cannot safely or accurately judge of the amount of light which a lamp will give by any statement of the watts which it consumes.

NEW YORK CITY, July 11, 1895.

TURBINE REGULATION WITH WATER RHEOSTAT IN AN HUNGARIAN MINING PLANT.

A rather difficult problem has had to be solved at the Kremnitz Mine, belonging to the Imperial Hungarian Government. Some time ago it was determined to put down plant for the electrical transmission of power to be utilized for the operation of a winding engine and a stone-breaking machine. The installation was carried out, a turbine being put down for furnishing the necessary motive power. Considerable difficulty was experienced owing to the variation in the load upon the turbine, and the manner in which this obstacle was overcome will shortly be referred to. The winding engine had to lift a net load of 15 cwt. at a speed ranging from 3 ft. to 5 ft. 6 in. per second, and it was required to drive this engine by means of an electric motor and to simultaneously actuate the stone-breaker by a second electric motor. The operation of the former is effected by a motor having a normal performance of 45 horse power. The greatest demand for power on this electric motor is experienced at the moment of taking up the load, and the power required attains various values according to the relative positions of the two ropes, ceasing the instant that the cage reaches the surface, when the electric motor is brought to rest. The regulation of the turbine was effected by the action of a centrifugal regulator. It was found when there was no load upon the generating dynamo—that is, when the electric motor operating the cage and that driving the stone-breaker were at rest—the turbine simply raced, the regulator only coming into action when the demand for power reached 12-horse power. Even at this demand the regulation was not sufficiently precise. Mr. E. Brossmann, one of the Government engineers, under whose supervision the mine is worked, then suggested that the difficulty at periods of no load might be overcome by means of a resistance energized by the generating dynamo. This method, however, was not adopted, and Messrs. Ernst Egger and F. A. Wessel devised a system of inserting an artificial load so as to keep the speed of the turbine practically constant under variable loads, which is a matter of considerable importance in installations of this kind. A liquid resistance was selected on the ground of cheapness and sparklessness on variations in the inserted resistance. The whole arrangement is entirely automatic, and as the load put upon the generator by the working of the winding engine and stone-breaker either varies or entirely ceases, the liquid resistance automatically takes up or absorbs the load whatever it may be, and the turbine and generating dynamo are thus enabled to run at constant load, quite independent of the working of the winding engine and stone-breaker.

ALTERNATE-CURRENT DYNAMO ELECTRIC MACHINES.

At a recent meeting of the Royal Society, Dr. J. Hopkinson and Mr. E. Wilson read a Paper dealing experimentally with the currents induced in the coils and in the cores of the magnets of alternate-current machines by the varying currents in and the varying positions of the armature. It is shown that such currents exist, and that they have the effect of diminishing to a certain extent the electromotive force of the machine when working on resistances as a generator without a corresponding effect upon the phase of the armature current. It is also shown that preventing variations in the coils of the electromagnet does not, in the machine experimented upon, greatly affect the result, and that the effect of introducing copper plates between the magnets and the armature has not a very great effect upon the electromotive force of the armature, the conclusion being that the conductivity of the iron cores is sufficient to produce the main part of the effect. A method of determining the efficiency of alternate current machines is illustrated, and the results of the experiment for this determination are utilized to show that in certain cases of relation of phase of current to phase of electromotive force, the effect of the local currents in the iron cores is to increase, instead of to diminish, the electromotive force of the machine. The large majority of the experiments described were made in the summer of 1893.

PERSONAL.

MERLE J. WIGHTMAN.

Merle J. Wightman.

One of the most active and prominent of the younger engineers engaged in electric railway work is Mr. M. J. Wightman, whose portrait is given herewith. He was born in January, 1865, and first became interested in electrical matters while attending the High School, Taunton, Mass., in 1878-9, at which time he constructed a dynamo of about 1 H. P. capacity, doing all the work on an old fashioned wood turning lathe and covering the wire with a special machine built for the purpose. In 1880 he built a larger dynamo, which was so practical that in 1884, it was used in the Schuyler works at Hartford, Conn., as a motor, to drive the blacksmith's forge. Mr. Wightman's education was finished at the end of 1883, at the Polytechnische Hochschule, Hanover, Germany. He then entered the United States Electric Lighting Co.'s service at Newark, N. J., as an apprentice. Soon after he passed into the employ of the Schuyler Electric Co. at Hartford, and in 1885, in conjunction with Herman Lemp, he was elected chief electrician of the Company. Alone or in association with Mr. Lemp, he obtained about 50 patents in the field of electric lighting, in relation to arc lamps, dynamos, dynamo regulators, series incandescents, &c. In 1887, he joined the Thomson-Houston Co. to develop their electric railway apparatus, and remained with them until 1890, taking an active part in such work. Where so much was done, it is difficult to specify individual performances, but it may be noted that Mr. Wightman developed and put into service the first series multiple controllers. Mr. Wightman had, however, an interest in other work, and was associated with Prof. Elihu Thomson in the development of the single phase alternating motor and the Thomson recording wattmeter.

In 1890, Mr. Wightman left the Thomson-Houston Co. to organize the Wightman Electric Manufacturing Co. of Scranton, Pa., which concern put on the market the first successful single reduction railway motor. In 1891, the company passed into the control of the Thomson-Houston Co., which moved in a mysterious way, once again, its wonders to perform, by practically closing the concern up. Thus left free, Mr. Wigthman became the consulting engineer of the Steel Motor Co. of Cleveland, for whom he designed the "Steel" motor and controller now manufactured by them.

At the present time, Mr. Wightman is the consulting electrician of the Johnson Co. of Johnstown, Pa., where he is engaged in work intended to solve the electric railway conduit problem. He is also interested in several street railway enterprises and is engaged in general electrical engineering work. He is also interested in electrical navigation, in which he has done some ingenious and original work. Mr. Wightman has been a member of the American Institute of Electrical Engineers since 1889.

ELECTRIC DISPERSION.

Mr. P. Drude, in *Wiedemann's Annalen*, describes a method for investigating the relation between the dielectric constant of a substance and the period of the electric waves traversing it, or what may be described as the electric dispersion of the substance. If the dielectric constant decreases as the period increases, there will be normal, if it increases, anomalous dispersion. For alcohol dispersion was found to be normal, and of the same order of magnitude as its optical dispersion. Water showed abnormal dispersion with the large wave-lengths used, whereas ebonite showed no perceptible dispersion.

SUPPLEMENT.

ELECTRIC FREIGHT HAULAGE.

THE unanimity with which the proposition is now accepted that electric motors will soon handle the bulk of the local passenger traffic all over the country, is certainly remarkable. It seems but a few short months ago that the mere ideas of the application of electricity in any shape to existing steam roads was scouted and flouted in practical quarters. We have heard of one steam railway man who only this summer wrote angrily across the statement that his road would try electricity, the word "Bosh!" yet his president and directors have since then all pronounced in favor of the new power. Unless that gentleman, who is thoroughly estimable, shrewd and hard working, changes his mental attitude, he is apt soon to find himself out in the cold. It is a pity that the advance of a new motive power should be regarded as a personal affront by anybody; and we can only remind such stubborn folk of Stephenson's well-worn remark about the "coo" that persisted in standing in front of his new locomotives. As a matter of fact, we find most steam railway men genuinely interested in electrical work, and their feeling is reflected in the journals of their profession, which are discussing the subject on altogether sensible lines, and with no bias in favor of steam simply because it is an agency that their readers happen to be more familiar with. The *Railroad Gazette* sums up our own arguments when it says pithily: "It is the business of the intelligent railroad man to inform himself and that speedily, as to the bearings and limitations of this element" * * * There will be a radical and costly change, a fact which is already pretty well appreciated so far as track and equipment go, but apparently not so far as legal and social rights and obligations are concerned."

The *Gazette* points out that in 1893, the passenger earnings of all the railroads of the United States were about 25 per cent. of the gross total earnings. Mail and express earnings made about 4½ per cent. The earnings from freight were 68½ per cent. These figures vary somewhat by localities, but the percentages hold broadly. It also appears that out of the whole gross earnings only 1.8 per cent. was profit due to the whole passenger business. "It would seem" says the *Gazette* "as if this entire business might be surrendered and no great harm done, but in fact this meagre profit from the passenger business was about one-fourth of the whole sum available for dividends."

That is apparently a reasonable view of a very complicated situation, but the question arises whether it is not also a problem to hold the local freight business. We do not know of any statistics obtainable as to through and local freight business. On the New York Central the local passengers are about 100 times as numerous as the through, but that evidently is no criterion as to freight. On the Pennsylvania, east of Pittsburgh, the foreign freight cars in 1893 made 370,000,000 miles and the home freight cars 436,000,000; which would perhaps indicate that the local freight is in some degree measurable by the home car mileages. Be this as it may, it is a certain fact that a large number of street car lines are now hauling freight (55 in 1894) and that the number is increasing rapidly. The article which we abstract this week from the *Engineering News*

furnishes some interesting data on the subject; while it may be noted that in New Haven and Fair Haven a trolley freight road to handle scores of trains daily is approved, and that in Minneapolis Mr. Lowry proposes to extend his lines to the great grain belt encircling the city and to run grain cars over them, which as he says "can be backed into an elevator and unloaded with less red tape than is now in vogue among railroads." He expects before two years to see the major portion of the grain now handled by Minneapolis carried there by trolley.

It may be inferred, therefore, that the trolley is about to cut deeply into much of the local freight business, which the steam railroads will lose. But the possibility of making the trolley into networks feeders for through steam freight is one that has much to be said in its favor and one to which we expect to see steam railroad managers direct their attention.

SUCCESS OF "THE ELECTRICAL ENGINEER" DATA SHEETS.

With this issue is published another of THE ELECTRICAL ENGINEER Data Sheets. We are glad to say that this new departure has made an immediate,—we might say, unprecedented—success, in the field of electrical journalism. Not only have we received many compliments from old readers and subscribers, but the number of new subscribers, wishful of securing this Data in such a form, is remarkable. The cases for filing the Data Sheets are also in great demand, and appear to be highly appreciated. The publication of the Sheets and the use of the Filing Cases enables an engineer to avail himself of the latest information on the subject, and he has a pocket book that is always up to date. We take this opportunity of thanking the many correspondents who have volunteered their readiness to contribute or verify Data, and to say that their offers of assistance in this important work will be freely availed of.

UNCLE SAM AS ANTI-BELL TELEPHONIST.

WHEN Judge Carpenter handed down his decision declaring the Berliner transmitter patent void, commendations were heard on all sides at the bold stand that had been taken by the Government in contesting the validity of its own grant. The recent decision of the U. S. Court of Appeals has, however, put the Berliner patent into valid standing again, and, unless upset by a suit for infringement brought in the regular way, it is good for the tenure of its original grant of 17 years. The Government's unsuccessful attempt against the Bell Co., would appear not to have dampened its ardor, for we learn that the Interior Department at Washington has just been fitted up with 140 instruments of the Western Telephone Construction Co.'s make, connected to a central switchboard, and that if the system proves successful, as it now promises to do, other Government departments will be similarly equipped. Before accepting the instruments, one of the examiners in the Patent Office investigated the system and upon his recommendation it was installed. The system having been adopted on the recommendation of such an authority it is evident that the Government has been throughly advised as to the responsibility it has assumed in installing a battery telephone system; but it is said that the Interior Department officials have no fear of suits for infringement, although the company supplying the apparatus is under an indemnity bond. It would be interesting to know on what grounds Uncle Sam bases his confidence in being allowed to use a carbon transmitter without molestation, or does he suppose that he will be more successful in the role of defendant in a suit for infringement than in that of complainant in a suit for cancellation of one of his own patents? Then again, is it not a most horrible spectacle to behold Uncle Sam setting such a bad example to his seventy millions of children, sixty-nine and three quarter millions of whom will be prone to do likewise and take refuge under his protecting coat tails. Truly the moralist has here a fine text for a sermon, but we are afraid that it will require something more than moral suasion to induce Uncle Sam to relinquish his own neat little private telephone exchange, or to stop installing others.

HORSELESS VEHICLES.

The recent race of horseless vehicles in France between Paris and Bordeaux was so interesting and successful that the attention of the whole world has been drawn to the subject, and inventors in America are now trying their hand in this field of mechanical traction. To make the effort in some degree remunerative and to stimulate work in this important direction, the Chicago *Times-Herald* has offered the sum of $5,000 to be expended in prizes to winners in a race between Chicago and Milwaukee next November. The terms are as follows :—

First prize—$2,000 and a gold medal, the same being open to competition to the world.

Second prize—$1,500, with a stipulation that in the event the first prize is awarded to a vehicle of foreign invention or manufacture, this prize shall go to the most successful American competitor.

Third prize—$1,000.

Fourth prize—$500.

The third and fourth prizes are open to all competitors, foreign and American.

Details as to the exact date, and as to the regulations, will be published in the near future.

We hope to see some electric carriages entered for this contest and that they will make a better showing than did those competing recently in France, where the petroleum motors proved immeasurably the superior in speed among 100 competitors. The winning petroleum carriage made the round trip of 750 miles at the marvelously high average rate of 16 miles an hour. We do not know of such a record being approached anywhere by electric vehicles, which generally are very heavy and must necessarily be dependent upon the renewal of their batteries, although, as an offset, they are said to be by far the cleanest, coolest and most comfortable. On American roads, no such speed over so long a distance could possibly be made by any vehicle, as our remote rural roads are usually bad beyond description while the French roads everywhere are as a rule superb.

The round trip between Chicago and Milwaukee would probably cover 175 miles, and if the winning vehicle—electric or any other—covers the distance at an average gait of 12 miles an hour it will be doing remarkably well. There is a great field here to be won by mechanical traction, and, as was predicted by the writer several years ago, trolley carriages will in all likelihood occupy a large portion of it.

ELECTRIC TRANSPORTATION DEPARTMENT.

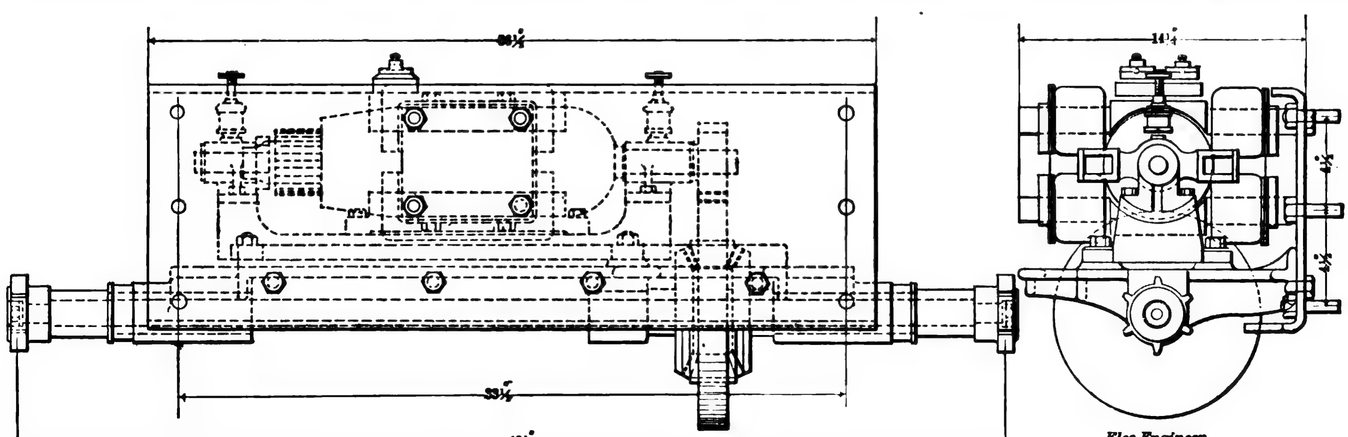
AN ELECTRIC CARRIAGE IN BOSTON.

FOR several weeks past the inhabitants of Boston and its suburbs have witnessed the novel sight of a carriage proceeding along the streets and roads at a good speed without any apparent means of propulsion. The absence of all smoke, puffing, or escape of steam, at once betrays the nature of the propelling power to be electricity.

In designing this electric carriage the result sought for by the owner was not to produce a vehicle of light weight and suitable for short runs only, but rather a carriage of the most substantial construction capable of prolonged runs at various speeds and with a seating capacity of at least six or seven persons. The general design of the carriage is the English brake, as this type seemed to lend itself most readily to the convenient distribution and handling of the batteries which are contained in the body and under the front seat. The top or cover to the body supports the two rear seats and is hinged so that it can be raised and thrown over against the front seat, leaving the cells and all connections accessible for examination or repairs.

The running gear is most substantially built and will stand the heavy strains on rough roads and under heavy loads without any liability of damage to springs or wheels, the latter being provided with ball bearings which reduce the friction very materially.

ELECTRIC ROAD CARRIAGE, BOSTON, MASS.



SIDE AND END ELEVATION OF ELECTRIC MOTOR AND DIFFERENTIAL GEAR OF ELECTRIC CARRIAGE AT BOSTON.

The body is water tight, and acid proof paint has been used very liberally so that under no circumstances can spilling or breakage of a cell cause damage to the motor or connections underneath. The usual fifth wheel and swinging front axle have been discarded and in its stead the axle is jointed just back of the wheels and fitted with heavy crank levers which in turn are geared to the steering shaft. The latter is provided with a bicycle handle, as shown, and a toothed segment with spring latch is also arranged so that by a slight pressure of the operator's foot the front wheels may be locked at any angle.

The battery consists of 44 Chloride cells and has a total capacity of 200 ampere hours with a normal discharge rate of 25 amperes. The cells have been put to most severe tests in hill climbing and heavy roads and have stood up to the mark most admirably. They are arranged in four groups of eleven each and are connected to the motor through a series parallel controller which puts the groups in multiple, series, and multiple series, respectively; this is operated by the lever shown alongside the steering shaft and is locked in the various positions by engaging with a notched arc and spring latch. This arrangement gives three well defined speeds and no rheostat has been found necessary.

The motor is of 4 H. P. capacity, series wound, and the engraving Fig. 2 shows its connection with the running gear. The phosphor

bronze armature pinion engages with a carefully cut intermediate gear the shaft of which is divided and connected through a differential gearing, allowing each half to run at varying speeds when turning corners, etc. This intermediate shaft drives the hind wheels directly by chains on each side, as shown in Fig. 1; the motor and gearing are protected by a light leather casing. A reversing switch for convenience in backing is mounted on the controller arc and is interlocking with it so that the motor cannot be reversed until the controller lever is placed to "off." The carriage can be guided by one hand at any speed, notwithstanding its weight, which is 5,100 lbs.

The speed may be varied from 4 to 14 miles per hour, and all ordinary grades are mounted with ease. Two 10 C. P. lamps furnish light on night runs. The brake is of the usual coach type and has been found sufficient for all purposes.

The electrical work on this novel form of vehicle has been admirably carried out by the Holtzer-Cabot Electric Co. of Boston and the carriage was built by Messrs. Chauncey Thomas & Co. of Boston.

FREIGHT TRAFFIC ON ELECTRIC RAILWAYS[1].

With the rapid increase of suburban and country electric railways, and the practice of carrying freight traffic on such lines, a demand has arisen for cars especially designed for this traffic, and several different types of these cars are shown herewith. The

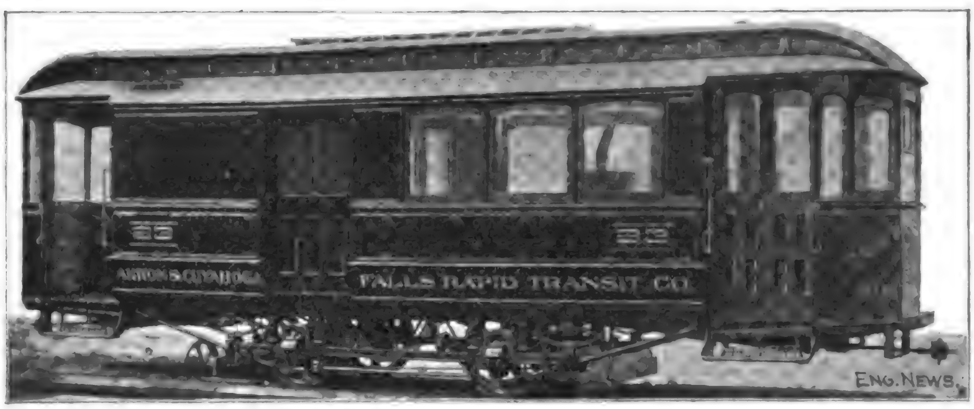


FIG. 1.—COMBINATION CAR, AKRON & CUYAHOGA R. R.

most common type of car for such service is a combination car having a passenger compartment and a freight compartment, as it is only in comparatively few cases that it pays to have cars for freight exclusively. With the combination car, mails, parcels and a limited amount of heavy freight may be carried, thus giving a frequent service without running cars any more frequently than is required for the passenger service.

The combination car shown in Fig. 1 was built by the J. G. Brill Co., of Philadelphia, Pa., for the Akron & Cuyahoga Falls Rapid Transit Ry. The body is 20 ft. long, and is divided into two compartments of equal length, one for passengers and one

FIG. 2.—SPECIAL OPEN FREIGHT CAR, MCKEESPORT ROAD.

for baggage, while the vestibules are of exceptional size, being 5 ft. long. The passenger compartment is handsomely finished in cherry. The baggage compartment is sheathed to the top rail with oil-finished hardwood. The car is mounted on a Brill rigid motor truck, with coiled bearing springs at the axle boxes and elliptical spring buffers at each end of the frame for overcoming vertical oscillation or pitching of the body, while semi-elliptical springs are used under the axle boxes. The car has the Brill adjustable truss, which prevents sagging of the ends.

Larger cars of this type are carried on two four-wheel trucks. An example is a car built at the same works for the Westminister & Vancouver Tramway Co., of Westminister, B. C. This car is 26 ft. long over the body and 33 ft. long over the platforms, which are open. The width is 6 ft. 10 ins. at the sills, and 7 ft. 6 ins. at the belt rails. The baggage compartment is 8 ft. 8 ins. long, and the passenger compartment 17 ft. 4 ins. long, with a seating capacity for 24 persons. This car is carried on two Brill "maximum traction" tracks. The car weighs about 11,050 lbs. the body weighing 5,850 lbs. and the two trucks 5,200 lbs. The J. G. Brill Co. has built about 100 cars for this class of service.

The McKeesport, Duquesne & Wilmerding Ry., which forms a connection between the Pennsylvania R. R. at Wilmerding, Pa., and the manufactories and railways of McKeesport, operates combination cars, box freight cars and open trail cars for carrying vegetables to market.[2] These cars were built by the New Castle Car Mfg. Co., of New Castle, Pa., and one of the open cars is shown in Fig. 2. It is 26 ft. long over the platforms, 18 ft. long over the body, has removable sides 4 ft. high, and is mounted on a McGuire truck. For shipments of heavy freight a box car of 12 tons capacity is used, equipped with two 40 H. P. Westinghouse motors. The car is the same length as the open car, 7 ft. high inside, has sliding doors in the sides and ends, and is carried on a McGuire truck. There is also a train of trucks for hauling lumber, sand, bricks, theatrical scenery, etc. This railway is only 4½ miles long, but it effects a connection over a ridge where no route for an ordinary steam railway is practicable, and the existing main lines form a circuitous and indirect route. Passengers on the Pennsylvania R. R. for McKeesport were formerly compelled to go to Pittsburg, change to the Baltimore & Ohio R. R., and then return to McKeesport, making 29 miles of travel from Wilmerding. The height of the ridge is 1,200 ft., and the electric railway surmounts an elevation of 400 ft., having numerous curves and maximum grades of 11%. This electric line is now the

1. Abstract, from the *Engineering News*, July 11, 1895.

2. This road was described and illustrated in THE ELECTRICAL ENGINEER, Vol. XVIII., No. 324, July 18, 1894.

principal connecting route, and mail and express matter from the Pennsylvania R. R. arrives in McKeesport five hours earlier than formerly, while a day is saved in freight shipments from the East, as McKeesport merchants have their freight shipped to Wilmerding and then transferred to the electric railway. Mail is carried from the Pennsylvania R. R. over this electric line not only for McKeesport, but for transfer to three lines of steam railways centering at McKeesport. The time from Wilmerding station to the McKeesport post office is 40 minutes, and the mail is carried under the regular railway mail contracts, the government paying a certain amount per 100 lbs. per mile. This was the first electric railway with which the Adams Express Co. made a contract, and the express matter is ordinarily carried on the combination baggage and passenger cars, except when the shipments are large enough to require the use of the box car. For this service the railway company is paid monthly at a certain rate per 100 lbs. of matter.

A combination car leaves each end of the line hourly from 6 A. M. to midnight, the trip occupying about 40 minutes. These cars are 20 ft. long, having a 5-ft. compartment for mail and express matter, this compartment having wide, swinging doors. These cars and the ordinary passenger cars are equipped with two 25 H. P. Westinghouse motors. All cars are fitted with track brakes for additional safety on the heavy grades. This brake consists of a shoe between the two wheels. The mail, express and freight traffic is a profitable feature, as it does not interfere with the regular passenger service, and the frequency with which the electric cars are run makes the saving in time specially desirable for mail and express matter. At McKeesport the company has its own wagons to collect and deliver freight. Connection is made at this place with electric lines to Reynoldstown, Duquesne and Homestead, while at Wilmerding connection is made with other electric lines extending to Braddock, Glenwood and Pittsburg, so that there is a continuous electric railway route from McKeesport to Pittsburg, 20 miles. All the line is single track, with turnouts, and the track is laid with 52-lb. T-rails on chestnut ties spaced 36 ins. C. to C. The power house is situated at about the middle of the line. Coal is obtained from a neighboring mine, owned by the company. Taylor, Romine & Scott, of McKeesport, were the engineers of this road, and we are indebted to Mr. James L. Devenney, its general manager, for information concerning it.

A large baggage and freight car is used on the Rockland, Thomaston & Camden Ry., of Rockland, Me.[2] The body is 25 ft. long, 7 ft. wide and 7 ft. high at the centre. The length of platforms is 30 ft., and the distance C. to C. of bolsters 18 ft. 9 ins. The car was built by the Briggs Carriage Co., of Amesbury, Mass., and is carried on two four-wheel Bemis trucks, with a 25 H. P. General Electric motor on each axle.

The West Chester Street Ry. Co., of West Chester, Pa., is another electric line doing a freight business. The company operates as one of its branches a cross-country line five miles long, from West Chester to Lenape, built on land acquired by the company. At Lenape freight transfers are made with the Wilmington & Northern R. R., connecting with the Baltimore & Ohio R. R., and large quantities of local freight are brought from Philadelphia in this way, thus competing with the Pennsylvania R. R. for all store goods coming into the town. The freight traffic is considerable, and is expected in time to pay very well. The line is 5 ft. 2½ ins. gauge, equipped with the Edison system, and has 5 passenger cars, 1 baggage car and 1 gondola car, all built by the J. G. Brill Co., of Philadelphia. The latter cars carry all kinds of freight except live stock. The U. S. mails are carried between West Chester and Lenape for points on the Wilmington & Northern R. R., and the road has a contract with the United States Express Co. to carry all its business to and from West Chester, for which traffic the baggage car is used.

Two cases may be mentioned in which accommodation is provided for special traffic on electric lines, one being the handling of whiskey at Frankfort, Ky., and the other the handling of grain and flour at Spokane, Wash. The Capital Ry., of Frankfort, Ky., does a large business in carrying to the station of the steam railway the barrels of whiskey from large distilleries in the district, and uses for this purpose a large box car, which also carries general freight and supplies for local service, and is used as a locomotive, hauling three loaded box cars between the railway and the distilleries. The car, which was built by the Barney & Smith Co., of Dayton, O., is 28 ft. long over all, 22 ft. 5 ins. long over the body, 8 ft. 4 ins. wide over the sills, 7 ft. 10 ins. high from sills to top of roof, and 10 ft. 8 ins. high from rail to top of roof. The platforms are open. The car is mounted on a pair of four-wheel trucks, with a 25 H. P. motor on each axle, and weighs about 15 tons empty. The line runs through a difficult country and has maximum grades of 8%, with, in one case, a reverse curve on a 7% grade, which, however, the motor car can pass with two or three loaded railway box cars. The track is of 56-lb. T-rails.

The Spokane Street Ry. Co., of Spokane, Wash., hauls wheat and flour between the mills and the railway station, and has displaced the drays formerly used. The city passed an ordinance providing that the charge must not exceed 20 cts. per ton, or 15 cts. per ton each way if the car is loaded both ways; the minimum car load to be 5 tons, and the company to supply current and right of way over its tracks for any cars owned by the mills at a charge not exceeding $2 per car. The first car was built at the railway company's shops, and is of the ordinary type of box car for electric railways, but having enclosed or vestibuled end platforms. It is 20 ft. long over all, and the grain compartment is 12 ft. long, 6 ft. wide and 5 ft. 6 ins. high, with a capacity of 12,000 lbs., or 200 bushels of wheat. The compartment has side openings, fitted with grain doors. The floor is the same height as that of a railway box car, and underneath it is a steel hopper, the floor being hinged so as to uncover the hopper when raised. At the freight station the floor is raised and the car loaded with grain from the main line cars. On reaching the mill the car is run over a chute, the gate of the hopper is opened and the grain is dumped. The floor is then let down to cover the hopper and the car is loaded with bags or barrels of flour to go to the railway station. The car has also been used for carrying and discharging broken stone for macadamizing the streets along the line. It is mounted on a four-wheel Brill truck with 30-in. wheels and 6 ft. 6 ins. wheelbase, and has an Edison double reduction motor on each axle. The line has grades of 4½ and 5½ per cent. and has a curve of 55°.

2. This car was illustrated and described in THE ELECTRICAL ENGINEER, Vol. XV., No. 252, March, 1893.

AIR VS. ELECTRIC BRAKES.

BY H. WELLMAN.

Upon reading the article of Mr. J. C. Henry, in your issue of June 26, regarding air or electric brakes, I am inclined to the belief that the writer is unjustly prejudiced against the air brake. He cites as a possible illustration his trouble in keeping tight pipe joints, piston valves, etc., during experiments conducted some six or seven years ago. This, I should think, is entirely aside from the question and should not be compared with all modern work in this line, as successful air and steam piping is general on all railway coaches and has been for years and the piping of a street railway car for air is not considered at all as difficult engineering.

I fully agree with you in the clause in your editoral under date of May 29, viz., that the air brake on street car lines is as inevitable as it has proved to be on steam roads. The above writer also makes mention of the numerous parts required in an air brake system complete as a braking unit; also of the fact that on most electric cars, there is no room for air pump on car axles. These defects are in my opinion slight and easily overcome, for the reason that for public conveyance and convenience, the stress is for larger and longer cars using double trucks, thereby affording ample room for eccentric air pumps or compressors to be placed on car axles. Air pumps run by a separate motor, as those used on the Intramural World's Fair Road, also the ones used on the Metropolitan Elevated at Chicago, are very successful and run with only a moderate amount of attention. They are very economical and are entirely automatic, keeping a constant air pressure in the reservoir underneath the car. The air compressor designed by Prof. Short, and mention of which is made in his recent paper read before the Cleveland Electric Club, is a very complete machine and contains many meritorious features, as well as economizing space. I fully agree, that it is criminal to operate street cars without *either air or electric brakes*, but certainly am not of the opinion that the days of the air brake are numbered. In fact, I think that the importance of the air-brake on street car lines is just beginning to be appreciated by the street railway fraternity. Taking it all around, there are about as many parts to keep up in repair, in a complete system of electric brakes, as with air brakes, and until the electric brake can successfully hold a car on a heavy grade after stopping, the advocates of the same can hardly hope to compete with the modern air-brake equipment now being very largely installed.

As quoted by Mr. Henry, the ideal electric brake should not depend on the live current, should be as near as possible frictionless, and the retarding force should be proportionate to the speed of the car; provided, of course, that the motor be converted into a *temporary* generator, by changing terminal contacts at the controllers. The electric brake as at present constructed, certainly brings a car to a stop in a very satisfactory and easy manner, but on grades they have to be supplemented by the vigorous use of the hand brake, to hold the car until ready to start; for, as is well known, as soon as the car stops and is at rest, the generating power of the motor is lost and there is (excepting that caused by a slight amount of residual magnetism) no retarding force or adhesion of the magnetic brake gripping the disc on the car axle or wheels.

It seems to me that a low voltage electric brake could be constructed, taking current from a number of cells of accumulators placed under the car seats. These cells need not necessarily be of great number and could be charged from the live current. A combination of this kind would hold a car as successfully on a steep grade as on a level, and with no use whatever being made of the hand brake.

Taking it all around, there would be about the same amount of labor in keeping up a system of electric brakes as of air brakes, and until the electric brake can successfully hold a car on our

steepest grades, the advocates of air can rest easy on their laurels, not mentioning the fact of other advantages arising from having air on cars. An important advantage is the whistle, and especially so in suburban roads and thinly settled districts; other advantages could be mentioned, such as cleaning snow from trolleys in winter and for the thorough cleaning and blowing out of motors and controllers of all copper and carbon dust, cotton, etc., thereby saving an immense amount of labor and lessening the evils and expense of burnouts so prevalent with dirty and dusty electrical apparatus. It seems to me that the braking of all cars has resolved itself into one or the other of the very small evils, namely, either the storing of air underneath cars in reservoirs or the storing of electricity in accumulators placed on cars, thereby holding "*on tap*" the necessary braking force. The future will undoubtedly bring forth numerous improvements on both air and electric brakes and I am fully convinced that important inventions in this line will fully keep pace with the growing and increasing demand for electric cars of all kinds, both for our street and our trunk line railroads.

EXPERIMENTING WITH THE BALTIMORE TUNNEL TROLLEY.

A special dispatch from Baltimore, of July 8, says:—The large electric locomotive with which the Baltimore and Ohio Railroad Company is experimenting in its tunnel under this city failed today to move a train of twenty-four loaded coal cars and a steam locomotive. It was too much of a pull for the motor. The coal train was to have gone north. The motor was in charge of William Cooper, who has been testing it since its arrival here. In addition, there were aboard the motor Dr. Louis Duncan, the Baltimore and Ohio Railroad's consulting electrical engineer; S. H. Browne, his assistant; L. H. Parker, the representative of the General Electric Company, of New York, and Mr. Potter, an electrical engineer from Schenectady, who designed the controller of the motor. The start was a slow one, and it was evident that the test was about all the motor could stand. When the middle of the tunnel was reached the shoe of the trolley was found to be red-hot, and the connection from the shoe to the car broke. There was no time for repairs, for northbound trains were expected. So the locomotive to which the cars were attached made an effort to pull the motor, train and all, but it could not budge them. The cars were then divided into two sections, and the motor and nine cars were first taken through, and then the fifteen cars were pulled through by the locomotive. The electrical engineers say that the trouble experienced to-day can be remedied, and that the test will be repeated in a few days.

A special dispatch from Baltimore of July 11 says:—A new explanation is now given of the failure of the large electric locomotive on the Baltimore and Ohio road to move thirty loaded coal-cars and a steam locomotive through the tunnel in Monday's test. Engineers Parker and Cooper of the General Electric Company say that the conduit through which the brass shoe, which takes the place of a trolley wheel, runs, had been up several months, and a great deal of dirt and rust had accumulated in it, which was not all got out by the few trial trips made. With a heavy load, this dirt and rust in one place offered so much resistance to the current as to create enough heat to expand the shoe and wedge it in the trough. This is considered sufficient cause for the failure of the test, and a gang of men has been set to work with scrapers cleaning the conduit and preparing for another test.

On July 12, a further test of the road was made, and proved quite successful, the cleaning out of the trolley duct overhead removing from the circuit the resistance that had prevented the proper flow of current.

THE TROLLEY FREIGHT ROAD FOR NEW HAVEN, CONN.

The trolley freight road (Manufacturers' Street Railway Co.) has now been approved by the councilmen as well as the aldermen, and the Mayor is expected soon to sign the ordinance. If the manufacturing development in Fair Haven is as great as is expected, 250 trains a day will become necessary, within the next five years, to handle the freight.

TROLLEY WIRES FOR BICYCLES.

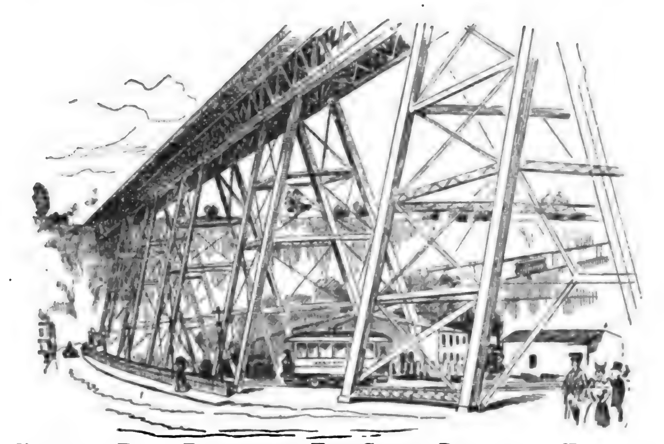
Being interviewed recently on the subject of bicycles, Mr. Edison said: "I believe that it is a matter of only a few years at most before hundreds of miles of special bicycle roads will be built with single line trolley wires overhead; especially in the mountains. Riders will have motors on their wheels which can receive current from the wires by trolleys so that quick spins may be taken. This would open up a new field of pleasure and usefulness to the devotees of the wheel.

"The system of driving tricycles by storage batteries and electric motors will undoubtedly be in use in a short time. Storage batteries have not yet been devised that would be light enough and small enough to be carried on bicycles, but I believe that batteries powerful enough to send a tricycle 20 or 25 miles and return, on good roads, could be made to weigh not over 60 pounds. A motor weighing 20 pounds would probably be sufficiently large to attain with this size battery a fair speed on a level road. A few years will probably see the system applied to trucking goods in city streets."

THE TROLLEY AT WEEHAWKEN HEIGHTS, N. J.—DISPLACING AN ELEVATOR AND STEAM ROAD.

One of the prettiest of the nearby resorts of New York City is Eldorado, a pleasure garden lying along the first spurs of the Palisades of New Jersey, and directly opposite West Forty-second street, the trip across the Hudson River being made in the West Shore Railroad ferry boats. The view up the Hudson valley and down the Bay to the ocean is enchanting, but there has been a serious drawback in the difficulty of reaching the lovely spot. For a long time, the ascent could only be made by an endless flight of wooden stairs or by ramshackle coaches plying over a very rough road. The increase in the popularity of the resort, together with the growth of the suburban population in that vicinity led finally to the erection of a huge elevator, at a cost of over $500,000, connected to the cliff by means of a trestle out upon which ran steam cars to receive and deliver passengers. The elevator cars, of which there were three, were of enormous size, each being able to lift about 200 people at a time. Even this arrangement has often proved inadequate to dispose of the crowds arriving from the ferry or returning to New York, after the performance at Eldorado or the races at Guttenberg.

When the elevators were put up, the trolley system was still young and was not considered adequate to such grades as were presented by the steep winding road; while an inclined plane was out of the question. But times have changed, and the trolley car has now been triumphantly introduced, so that the horse stages are abandoned, the elevators stand idle waiting to be torn down, and the trestle no longer will quiver under the oscillation of the steam cars. The trolley cars that have been put in service take the passengers quickly up the bluff and then in three different



Trolley Road Displacing The Steam Road and Elevator at Weehawken, N. J.

directions out into the suburban region on the westerly slope of the Palisades.

The roadway from the ferry has practically been remade and solidified, and a heavy iron railing has been put between the tracks and the edge of the road as a preventive of accidents. The cars have each two four-wheeled trucks and are equipped with powerful hand brakes.

As a matter of fact, the whole steam system of the North Hudson County road connecting with the ferry is being converted to electricity. At present six of the old steam cars have been made over into trolley cars, as described, with Brill trucks, and General Electric motors; and these run up as far as Hudson Heights, over the old steam tracks, making as much as thirty miles an hour. The remaining dozen cars are now, it is said, to be converted and the whole line up to Fort Lee will be operated electrically by the Fall of the year. The steam tracks have simply been bonded and poles set each side to carry the span wires. Current is fed into the system from the two power houses of the road furnishing the other connecting trolley lines.

Milwaukee, Wis.—The proposition to enforce 4 cent car fares by city ordinance, has practically fallen through, the aldermen putting it on file without vote.

Windsor Beach, near Rochester, has an electric fountain, on the lines of those at the World's Fair. It is lit by a special 20 H. P. dynamo and the water is pumped by a 30 H. P. motor. It runs nightly every 15 minutes between the hours of 9 and 11, and is described as very pretty.

THE PROBLEMS OF ELECTRIC RAILWAY WORK.[1]

BY OSCAR T. CROSBY.

LONG-DISTANCE electric railroading is a mere question of the magnitude of the amount of capital invested. The work to be done cuts almost no figure; that is, electric locomotives can easily be made and have been made to handle the maximum freight or passenger service. The Baltimore and Ohio road is just about beginning the operation of three electric locomotives, carrying trains through the tunnel in Baltimore, in order to avoid smoke and gases. As long as three years ago I made a contract with the Baltimore and Ohio Company for this work with the Thomson-Houston Electric Company. The real question as between the proper use of steam and electricity on any given line is one of frequency of service, and this becomes important because upon it depends the economy with which a central station may be operated. It should be remembered that back of all electrical generators we must still supply some prime mover, and, practically, this prime mover must be either a steam engine or a water wheel. While water power will rapidly come into play it remains true that large sections of country must for many years depend upon the steam engine as the primary source of electrical power.

In such cases the economy to be obtained, if any, by electric locomotives over steam locomotives will depend upon two things. First, the difference in coal consumption for a unit of power in a large stationary engine plant, as against the lower consumption of a locomotive which works under comparatively trying conditions in regard to this point. Second, the greater economy in the matter of repairs in an electric locomotive over a steam locomotive, and this extends to a lower maintenance account to the track, which is less injured by an electric locomotive of a given weight than by a steam locomotive. Out of these two economics we must get enough to pay an increased interest charge (because the electric roads cost more than the steam railroads) and we must also cover the amount of power wasted in transmission from the central station to the locomotives.

The result of these conditions would be in favor of the steam locomotive unless the central station can be operated under advantageous conditions.

It is plain that no central power station is working advantageously if the maximum power for which it is established should be called for only a short while each day.

Let us assume a somewhat extreme case, namely: That a certain section of road which is being supplied by a central station is fifty miles long, and two trains, each requiring approximately 1,000 horse power at the station, should come together on this section and occupy it for say two hours, and that during the remainder of the twenty-four hours the station would not be doing any work. It will appear to every one that in such a case such a central station would develop its power at a very high cost per unit. If, on the other hand, such a station could be developing approximately its full power for twenty-four hours, the cost of power per unit would be very much lower. An example of this latter case is seen in the ordinary central station for street railway service.

The value of all the elements entering into the problem have been carefully calculated by me and the results published in papers presented to scientific societies and in Crosby and Bell on the Theory and Practice of Electric Railroads.

Without going into the detail of such calculations, which are extremely uninteresting to those not required to follow the subject, it may at once be said that there is no steam railroad service in the Southern or Western States that could profitably be changed to-day into electric service. On the other hand it may also be safely said that the service of the Pennsylvania road between New York and Philadelphia, and the service of the Consolidated road between New York and New Haven, and the service of the New York Central road as far north as Yonkers could be performed at slightly less cost by electricity than by steam. Likewise, there is no question as to the desirability of electricity over steam on any elevated railroad in a large city where the trains are necessarily run at frequent intervals. In this particular case, also of city service, there are other advantages quite aside from those of economy. There are the superior cleanliness and less noise.

For all classes of service electric locomotives offer an advantage over steam which the world will more and more learn to appreciate; that is, very high speed. The maximum recorded speed of a steam locomotive with train is 112 miles per hour, made over only a few miles on the New York Central road, near Rochester. The maximum recorded speed of an electric locomotive is 120 miles per hour, made experimentally under my direction a few years ago. But these figures do not in themselves give proper comparison of what can be done by the two methods. Aside from the mechanical difficulties of reciprocating action, which alone would seriously hold down the speed of the locomotive, the controlling influence which would limit the speeds of locomotives very nearly to those which have been attained already, lies in this, that the boiler is unable to furnish sufficient steam at a high pressure for any considerable run. An electric locomotive on the other hand, since it receives its power in an intangible and imponderable form may maintain indefinitely any speed it may attain for even a minute under any given conditions.

The dead weight to be carried by an electric locomotive is less than in the case of steam, and it may also be arranged to produce less atmospheric resistance for a given load behind the draw bar. This matter of atmospheric resistance becomes of considerable importance only when the considerations of abnormally high speeds are in question.

Substantially as we move on in the matter of speed, say beyond 100 miles an hour, we are driven almost exclusively to the use of the electric locomotive. At the time the high speed experiments above mentioned were made by me there was considerable skepticism even among electrical engineers as to the feasibility of any great advance in the matter of speed. Meanwhile, however, so much has been accomplished practically and theoretically that all well-informed experts are agreed that nothing save the inertia of capital now lies between civilization and a transport speed of 150 miles an hour. It is probable that the earliest line on which such high speeds will be regularly adopted will be that between New York and Philadelphia.

Speaking of speed, but coming to a lower plane, I can say that the people of New Orleans can be congratulated on having what is probably the highest speed of trolley cars in the country. This is due to the flatness of the city and the existence of so much of what is here known as neutral ground. There are not many blessings connected with the peculiar topography of this city, and this particular advantage should therefore be the more cherished.

Among the things not permitted by your topography may be mentioned the underground electric railroad; that is, the electric railroad in which the conductors or trolley wires are placed in a conduit similar to the conduits carrying the wire rope in the cable car system. A few years ago I saw a very satisfactory example of such an underground railway in Buda-Pesth, in Hungary. A short line, similar in general construction, has for some time been operated in Washington, and a more considerable plant is now being built in the same city, while in New York the Metropolitan Traction Company are just beginning the operation of three or four miles of track equipped in the same way. The same causes which leave the streets undrained and unsavory at times would render the application of this method quite impracticable in this city. The matter, however, is chiefly one of æsthetic value, since the ordinary operation of the cars is in nowise improved; the expense of insulation is much greater, even in favorable topography, and the only advantage gained lies in getting the wire and poles out of the streets. As to the present status of electric lighting, that which has been done during the past few years is rather the improvement of detail than change in any radical element of the problem. Some comparatively new forms of machinery, known generally as those of the multiphase type, have been adopted under the pressure felt for increasing the distances over which electric power may be commercially transmitted. As a mere matter of engineering possibility it should be borne in mind that electric power may be transmitted 1,000 miles with any small percentage of loss desired, but such a thing would not be commercially possible because of the immense cost of the conducting and insulating devices required for such distances. The effect is to increase the electrical pressure or tension at which the power is transmitted, since such increase of pressure carries with it a decrease in the amount of copper required. To-day there may be found in the ordinary street railway service where it extends to suburban lines instances where power is transmitted ten miles. There is an interesting instance of power transmitted from the falls of Tivoli to the city of Rome, a distance of eighteen miles. There are examples in this country, chiefly in the mining districts, of distances equal to this last named. Much longer distances of transmission may even now be justified in cases in which the cost of developing the water power is not large and the cost of coal not small; thus on the Pacific coast at Los Angeles coal is $11 per ton. In some of the neighboring mountains water power may be had, although at a distance approximating 100 miles. In such a case, even with present methods, it might be commercially desirable to make such a transmission. The climatic conditions on the Pacific slope are generally favorable in the matter of insulation; on the other hand, between Buffalo and Niagara Falls the climatic conditions are severe. It is in this locality that we assume to see much and learn much in the art of power transmission. The Cataract Construction Company are just beginning to use their first 5,000-horse power dynamo. The distance to the centre of the city of Buffalo is about twenty-two miles. Coal in Buffalo is very cheap, less than $2 per ton, yet there is no doubt that the Cataract Company will be able to sell power profitably at considerably less than the cost of power produced by coal. Between these two cities there is also just completed an electrical railroad on which the normal speed will be thirty-five miles per hour, and when I made the contract for building this road it was expected that we would be able to start with power from Niagara Falls. We may be dis-

1. *New Orleans Times Democrat.* Abstract of Interview.

appointed for a few weeks in this matter, but it will be only a question of two or three months when this fine example of force will be in daily use.

THE BRILL TROLLEY SPRINKLER.

We illustrate herewith two interesting forms of trolley street car sprinkler put upon the market by the J. G. Brill Co. of Philadelphia. Sprinkler building is no longer a casual branch of the art, but is conducted with care and a close study of details. The form, Fig. 1, as will be noted, has a roof over the tank for supporting the trolley. The length over the sills is 16 feet, the width over

FIG. 1.—THE BRILL TROLLEY SPRINKLER AT BALTIMORE.

the side sills 6 feet 10 inches. The approximate weight is 9,930 pounds. The cedar tank has a capacity of 2,390 gallons. The regular type of sprinkler has a 3-inch outlet, studded with 3-16 in. holes, but the latest pattern includes an improvement whereby the water is led to the orifice of the pipe which is practically plugged with a conical shaped spur. This has the effect of throwing the water in a film over the edge of the cone, and distributing it advantageously. There are also auxiliary sprinklers for soaking the rails thoroughly to ensure good contact. The tank is mounted on the Brill No. 7 independent non pivotal truck having solid

FIG. 2.—BRILL ELECTRIC SPRINKLER CAR FOR JERSEY CITY.

forged axle box frame. There is a radiating draw-bar at each end, and a brake handle. Many of these sprinklers are being placed by the Brill Co., the one shown being of the type in use on the Baltimore City and Suburban. Another special type of the same general design has been built recently for the Consolidated Traction Co. of Jersey City. The capacity is also the same, but the tank is of steel, without a roof. The spray thrown has a 12-foot range.

PENNANT FOR STREET CARS WITH UNITED STATES MAILS.

The Post Office Department has agreed upon a miniature pennant, modeled from the pennant used on steamships carrying the United States mails, for street cars carrying the mails. The pennant will be two feet long, red with a blue border, with the eagle and an inscription, "United States Mail," in white letters. The pennant will only fly when the mail is on the car.

MISCELLANEOUS.

THE WATER POWER CONTRACT AT KEOKUK, IA.

The contract between the city of Keokuk and the Des Moines Rapids Power company, whereby the city agrees to take 500 electrical horse power at $30 a horse power a year for a period of five years, has been signed by both parties. While the price is stated to be $30, it is provided that should the company furnish any other party, in the city or without, with power at a less rate, the price to Keokuk shall be reduced accordingly. The power company is bound to furnish power to all who demand it and at a reasonable and uniform price, not exceeding $30 for quantities exceeding 500 horse power and a sliding scale of prices for less amounts. To secure the faithful performance of the contract the city retains 12½ per cent. of the contract price until the end of each year. The city has the power to increase the amount of power it takes up to $1,000 at the same figure, and may renew this contract at pleasure. The power company agrees to begin work within six months from July 2, 1895, and have the plant in operation within a year.

UTILIZING THE WASTE WATER OF THE POTOMAC FOR ELECTRIC LIGHT AND POWER.

An extensive scheme is on foot for the utilization of the waste waters of the Potomac at Hagerstown, Md., for electric power. The matter is being pushed by a syndicate represented by Mr. Powell Evans of Philadelphia. At either of two dams in the Potomac River, conveniently situated in regard to Hagerstown, there is a foot and a half of water going over. This represents 4,800 cub. ft. a second, or 7,500 H. P. Sixty per cent. of this power can be transmitted to the town by electricity. The fall of the water at Dam No. 5 is eighteen feet. Here are located the Potomac Pulp Mills and water wheels are already up. These may be used by the company. At Dam No. 4 the fall of water is twenty-three feet. The new company is said to contemplate a street railway for Hagerstown, with extensions to Williamsport and Funkstown, the building of power houses, and the purchase of the electric light plant, in all to cost $300,000.

The stated plans of the syndicate are as follows: They propose to contract with the Chesapeake and Ohio Canal Company at Dams No. 4 and 5 and utilize the great water power at those points. A complete system of electrical street railway is to permeate the principal streets of Hagerstown. A continuation of the system is to extend to Williamsport, following the Williamsport pike, and a park is proposed to be built.

The electric light plant in Hagerstown it is proposed to purchase and operate in connection with the railway system. They also propose supplying power to the manufactories of Hagerstown at a rate greatly in reduction to that paid by the factories at present.

ELECTRIC POWER WANTED AT SLATINGTON, PA.

The Washington Slate Co., of Slatington, has been organized with a capital of $100,000. A. P. Berlin is president and manager. The company has opened a new quarry, and proposes to utilize electricity in its operations on an extensive scale. The plant will include mining machinery, hoists, pumps, and drills, and will presently be extended to the working of surrounding quarries. The central electric plant will be a 25 to 30 K. W. dynamo, 250 volts; a 25 H. P. motor for hoist; a 7½ H. P. motor for pump, and a 5 H. P. motor for drill. The conditions for the successful operation of electric power are so favorable that the company is desirous of communicating with reliable parties from whom to obtain estimates for this class of work. It is also desirous to interest capital for the erection of a large plant for the furnishing of electric power to conduct quarry operations in the district, as well as for street railway purposes and electric lighting. The company proposes to organize a special corporation for this purpose, and to take an active part in developing the exceptional possibilities which are presented.

COMMENDATION OF "THE ELECTRICAL ENGINEER" DATA SHEETS.

We are receiving many commendations of the ENGINEER Data Sheets, of which the publication has just been begun. Mr. W. A. Mosscrop ,M. E. of Ansonia, Conn., ordering a filing case for them writes: "These are a good thing; push 'em along." Mr. R. E. Clark of Berlin, Wis., writes: "Send me one of your filing cases, morocco, for Data Sheets. I think those Data Sheets are what has been long looked for by electricians. They are fine." Mr. F. C. Turner of Chicago "is quite taken with the Data Sheets and thinks they are a very fine addition to the paper." Mr. H. V. Parsell, Jr., writes: "I must congratulate you on the inauguration of the Data Sheet system. It is what I have been longing for and dreaming about. I hope they will appear quite rapidly just now, so as to fill up the long-felt want. Please send me a morocco filing case."

TELEPHONY.

MARSHALL DUPLEX TELEPHONE SYSTEM.

THE rapid increase in the use of the long distance telephone must soon bring forward the question of increasing the carrying capacity of the lines. In the telegraph the number of phantom lines, created by the inauguration of the duplex and quadruplex nearly equals in length those actually strung, and the time cannot be far distant when similar methods will have to be applied to telephony to keep down the cost of operation and maintenance.

Among the various methods of telephonic duplexing suggested

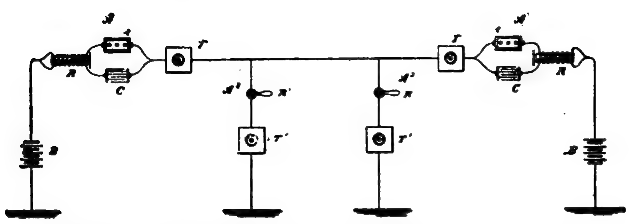


FIG. 1.—MARSHASL DUPLEX TELEPHONE SYSTEM.

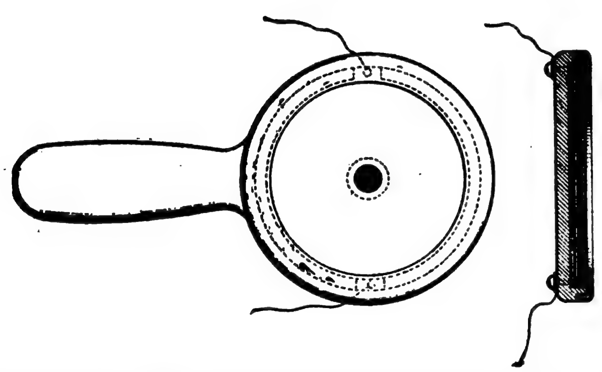
is that due to Mr. William Marshall, the well known condenser manufacturer, of this city, whose system is illustrated in the accompanying diagram, Fig. 1. Here A A' are two terminal stations of a telephone line and A^2, A^3 are two intermediate stations on the same line. At the terminal station A, is a battery B one pole of which is grounded. The other pole is connected to line through a receiver R, and a transmitter T. The line is branched before reaching the receiver, and one branch is wound



FIGS. 2 AND 3.—MARSHALL CONDENSER TELEPHONE RECEIVER.

around the core of the receiver in one direction, and the other branch is oppositely wound around the same core. Beyond the receiver one branch passes through a resistance coil or box *r* while the other is connected with the terminals of a condenser C. The two branches unite beyond the condenser on the one side, and the resistance box on the other. The transmitter T is an ordinary carbon transmitter, but the line is connected directly to its terminals, the usual induction coil being dispensed with. In

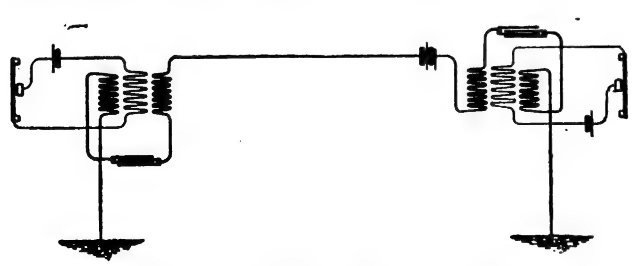


FIG. 4.—MARSHALL DUPLEX TELEPHONE SYSTEM.

this way the terminal station instruments operate by means of a direct or primary current.

The instruments at the other terminal station, A', are identical with those just described, and it is evident that operators at these two stations can communicate with each other in the ordinary way by means of their transmitters and receivers. In other words, the operation of the transmitter T, say at the station A, will affect the coil of the receiver R at the station R', or that part of the coil which is connected through the resistance box *r*. The other part of the coil which is connected through the condenser C. will be practically cut out and will remain unaffected by the direct current on line. At the intermediate station A^2, there is employed a transmitter T', connected to earth, and a receiver R.'

The receiver is a condenser receiver with alternate layers of tin foil and some thin insulating material as shown in Figs. 2 and 3. Every other sheet of tin foil is connected to the same pole or terminal of the receiver, while the remaining sheets of tin foil are connected to the opposite pole. This instrument makes an excellent receiver. It also serves in place of a condenser which by its alternate changes of static condition when the transmitter T' is operated, will affect the receiver at A^3 without disturbing or communicating with either of the terminal stations.

The connections at the terminal stations are illustrated in Fig. 4. It will be seen that the transmitter has two secondaries one of which is joined to line and to one pole of the condenser receiver and the other of which is joined to ground and the other pole of the receiver. The principle upon which this system operates is, that the direct current flows at the terminal stations through the branch containing the resistance and thus operates the receiver while the induced current flows equally through both branches without affecting the receiver.

SECRECY OF TELEPHONE MESSAGES IN NEW YORK.

An amendment to the penal code that will go into effect September 1, requires employés of telephone companies to maintain secrecy regarding the nature of the business carried on over the lines, the same as those who handle telegraphic messages are required to do.

A TELEPHONE STRUGGLE AT NEVADA, MO.

An injunction has been got out by the Missouri and Kansas Telephone Company, restraining the English & Haley Telephone Company from trespassing upon their lines by crossed wires. The wires of the latter company were cut in several places. The Missouri and Kansas Company has been operating its system for 10 years. The English & Haley Company was recently granted a franchise by the City Council and had secured a large list of subscribers at about half the rates charged by the old company. This action will result in keeping the new company out until the November term of the Circuit Court.

THE POSTAL TELEGRAPH SYSTEM NOT SOLD.

Mr. A. B. Chandler, President of the Postal Telegraph and Cable Company sent the following to the newspapers last week: "The recent publication of specific statements to the effect that the property of the Postal Telegraph and Cable Company has been sold to the Standard Telephone Company makes it necessary to say that no such sale has been made or contemplated, and no motive for the making of such a story is known either to the stockholders or the management of the Postal Company." What Mr. Chandler says at any time, on any subject—goes.

RAILROAD TRACK TELEPHONY.

A dispatch from Aberdeen, S. D. says:—A novel scheme is being considered whereby this city and Tacoma Park may be connected by telephone. It is proposed, providing the railroad company will consent, to connect a wire with a rail of the Great Northern Road at Tacoma, a similar connection to be made at this end of the line.

MUNICIPAL CONTROL OF TELEPHONES WANTED IN DULUTH

Some of the people of central Duluth, under the leadership of the Commercial Club, met last week and declared in favor of municipal control of the telephone franchise. The meeting was called because of a proposition now before the council to extend the time of the present company's franchise for a long term of years, which proposition includes the payment by the company of a considerable sum of money for the privilege of putting its wires in underground conduits.

MILDE TELEPHONES FOR CANADA.

The Montreal, Que. *Star* says:—Mr. T. A. Ness, of the firm of Ness, McLaren & Bate, Montreal, who has just returned from a trip to the Western States, while there closed a contract with the Standard Telephone and Electric Co., of Madison, Wis., for fifty thousand Mildé long distance telephone transmitters.

CENTRAL UNION THREATENS SUIT FOR INFRINGEMENT.

There is a telephone war at Mt. Vernon, O., and the Central Union Co. has served on all users of the opposition service a notice that all battery transmitters are considered infringements on the Berliner patents, and that infringers will be prosecuted.

TELEPHONIC "SPARKING" TOLLS AT EAU CLAIRE, WIS.

The superintendent of the Wisconsin Telephone company says the line is a sufferer by reason of the sparking and flirting carried on by the men and women of Eau Claire and Chippewa Falls. The company has adopted a rule that after a certain number of calls on the line between the two places a toll of 10 cents will be charged. This may have a tendency to reduce the conversation between the young people, and it surely will cut off many non-subscribers.

TELEPHONE NOTES.

SOUTH SALEM, CONN. is to have a telephone service.

MENASHA, WIS.—The Wisconsin Telephone company has been granted a franchise by Menasha.

ABERDEEN, MISS.—Under the supervision of Mr. Hugh Campbell a telephone service is being established.

MONTROSE, PA.—Work towards the putting in of the poles for the new local telephone company is progressing satisfactorily.

ASHEVILLE, N. C.—A company has been formed to erect a telephone line between Asheville and Rutherfordton.

WORCESTER, MASS.—The contracts for the erection of the new Bell telephone building have been let. The building will probably cost $60,000.

LE MARS, IA.—W. A Cottrell, of LeMars, has about completed the organization of a telephone company to build a line from Akron to Elk Point, S. D., and Sioux City.

RUMFORD FALLS, ME.—The Rumford Falls and Rangeley Lakes Railroad Company have bought the poles for a telegraph or telephone line to Bemis.

MADISON, WIS.—The Douglas County Telephone Company has been formed; capital, $80,000; incorporators, P. G. Stratton and Russell Baxter.

PITTSBURG, PA.—The new telephone company, of which J. N. Pew is president, is having plans prepared for the construction of the underground lines in the down town portion of the city.

CHAMPAIGN, ILL.—The Champaign and Urbana Phœnix Telephone Company has been formed; capital stock, $40,000; incorporators, P. S. Replogle, E. Frank Replogle and Jacob Frankel.

ELWOOD, IND.—J. M. Overshimer has purchased the Pana telephone exchange; consideration, $3,000. The exchange has two hundred patrons.

BETHANY, O.—The Bethany & Hughes Telephone Co. has been organized and is already operating a line from Bethany to Hughes Station.

NORTH CREEK, N. Y.—Leroy M. Carver, of Little Falls, has been awarded the contract for constructing a telephone line from North Creek, Saratoga county, to Newcomb, Essex county.

PENOBSCOT, ME.—The New England Telephone Co. extended their line from South Penobscot to South Brooksville and from Tapley's Corner to West Brooksville.

ANOKA, MINN.—There is a scheme on foot to start a local telephone exchange here. The projectors claim they have nearly enough signatures to warrant the building of the line.

CUTCHOGUE, L. I.—At a meeting of the stockholders of the Montauk, Orient and New York Telegraph and Telephone Company it was decided by a vote of 587 to 295 to sell out to the New York and New Jersey Telephone Company.

PIERRE, S. D.—Since the establishment of a telephone connection with Fort Pierre stock men of the range will build a line to Midland, a central point in the cow country, for the purpose of securing storm warnings from the weather bureau in that city.

MINNEAPOLIS, MINN.—There is a well-founded rumor afloat that the Northwestern Telephone Exchange will shortly put in a subcentral station in Minneapolis, to relieve the present overcrowding of the subway system.

PILOT MOUND, IA.—The Lower Vein Coal and Railway Company are putting up a line of telephone poles between Pilot Mound and Fraser, and will soon have a telephone service established between the two towns.

STAMFORD, N. Y.—The Mountain Telephone Company have decided to increase their capital stock to $2,100, with which to extend their lines from Prattsville to Ashland, and east to Catskill, via Cairo.

ALBURGH, VT.—A new telephone line has been completed connecting Isle La Motte and Alburgh. The line is owned and controlled by Hon. N. W. Fisk and E. S. Fleury, and connects the island, which has been hard to get at, with the telegraph office at Alburgh.

LITTLE ROCK, ARK.—The Little Rock Telephone Company has filed in the Secretary of State's office a certificate of an amendment to its articles of agreement and incorporation increasing the amount of capital stock to $100,000.

CHARLOTTESVILLE, VA.—The Interstate Telephone and Telegraph Company is just finishing up exchanges in Charlottesville, Va., where they have 100 subscribers, and Frederick, Md., where they have 200.

SALT LAKE CITY, UTAH.—At the regular meeting of the board of directors of the Rocky Mountain Bell Telephone Company, it was decided to double circuit the system between Ogden and Logan as soon as circumstances will permit.

JACKSON, MICH.—R. B. Watson, telephone manager here, has been called to Detroit to become purchasing agent for the Michigan Telephone Construction Company. The vacancy will be filled by C. E. Mower of the Three Rivers exchange.

LIBERTY, N. Y.—The Sullivan Co. Telephone Co. will extend its system from Liberty to Liberty Falls, Strongtown and on to Monticello, which when completed will make an excellent telephone system.

ST. JOSEPH, MO.—The Missouri and Kansas Telephone Company will begin work laying their underground wires in the central part of the city, and building their new exchange, as provided for in the franchise granted them some time ago.

COUNCIL BLUFFS, IA.—The Iowa Harrison Telephone and Construction company has been formed in this city with S. B. Wadsworth, S. L. Etnyre, C. E. H. Campbell, A. W. Johnson and C. M. Hard as incorporators. It has $100,000 capital stock, with a privilege of doubling that amount if desired.

SUPERIOR, WIS.—The Douglas County Telephone company has filed articles of incorporation. The capital stock is $80,000. The incorporators are Pear Benson, P. G. Stratton and Russell Baxter. They will buy, purchase, lease or otherwise acquire and maintain and operate telephone and telegraph lines.

CHILLICOTHE, O.—The Home Telephone Co. and the Clarksburg and Chillicothe Telephone Co. will in future be operated jointly. This means that the Home Co. can now give its subscribers connection with Frankfort, Roxabel, Andersonville and all the western part of the county.

BOONE, IA.—The Boone County Telephone Company, with place of business stipulated as the city of Boone, has filed articles of incorporation. The amount of capital authorized is $10,000. The incorporators are A. A. During, Chas. E. Wells, R. G. Schaaf, J. L. Stevens, W. H. Crooks.

SIOUX CITY, IA.—The Home Telephone Company of Sioux City has been incorporated. The place of business is given as Sioux City, and the capital as $70,000. The incorporators are T. H. Johnson, A. H. Hazen, A. F. Call, F. W. Lohr, E. E. Hazen, George H. Hollister, F. L. Eaton and Richard M. Dott.

BRIDGEPORT, CONN.—S. A. Boyd, representing a body of capitalists has made the following statement: We intend to put in a perfect system at an expenditure of $250,000 to $300,000, and offer the best of telephone service at $4 a month in offices and $3 a month in houses.

SALISBURY, MD.—The county commissioners have granted a franchise to Mr. W. H. Jackson to erect a telephone from Salisbury to his farm, on the Quantico road. A franchise was also granted Messrs. Sampson, Truit, Major Humphreys and Mr. S. E. Gordy to erect a line to connect their farm with the town line.

OSKALOOSA, IA.—The Iowa Telephone company has issued an order giving its 180 city subscribers free rental until further notice. The order was issued just as the new local company was ready to open its exchange with a list of 400 subscribers, most of whom have been paying exorbitant prices to the old company.

WINONA, MINN.—A contract has been let to Electrician Bell, of Winona, to construct a telephone system between this city and Galesville, Wis. The line will pass through Marshland and Centerville, and have connections at this end with one of the city telephone exchanges.

LAURENS, S C.—A charter has been issued to the Laurens Telephone Company. The officers of the company are: Directors, J. F. Traynham, B. F. Posey, J. H. Sullivan, E. H. Wilkins, W. R. Richie and O. B. Simmons; president, J. H. Traynham, vice-president, B. F. Posey, and secretary and treasurer, W. R. Richie.

COLUMBUS, IND.—The Citizens Telephone Company, (anti Bell) has entered into a contract with the Rural telephone company by which the two systems will be connected. This will give Columbus telephone connections with a number of the smaller surrounding towns including Hope, Hartsville, St. Louis Crossing, Clifford, Flatrock, Nortonsburg, Petersville, Newburn and Burnsville.

CONWAY, ARK.—The Southwestern Telephone Company is putting in a telephone system for the town.

BALTIMORE, MD.—The contracts which have been secured by the Home Telephone Company have been counted. The total number was 3,448.

ELIZABETH, N. J.—The Elizabeth Mutual Telephone Company has begun the construction of its telephone lines through the city.

CARBONDALE, PA.—An ordinance has been passed granting to the Carbondale Telephone Company right to establish and maintain a telephone system within the limits of the city of Carbondale.

MOBERLY, MO.—D. P. Moore has received the incorporation papers for the Moberly Telephone Company, of which he is one of the leading members.

KANSAS CITY, MO.—The Grand Avenue Electrical works is the name of a new telephone Company that is being organized to put in an exchange at Kansas City. It is a branch of the Standard Telephone company of Madison, Wis.

WASHINGTON, D.C.—Tired of paying what they regard as exorbitant rentals for telephones, the Commissioners will, upon the beginning of the next fiscal year, equip a telephone service belonging to the District.

COUNCIL BLUFFS, IA.—Articles incorporating the Wizard Telephone and General Electrical Manufacturing Company of Council Bluffs have been filed. The capital stock of the company is $100,000.

FRAMINGHAM, MASS.—The Framingham selectmen have granted a franchise to the Framingham Telephone Company, a new corporation, capitalized at $15,000, which proposes to furnish service in Framingham and Natick.

ISHPEMING, MICH.—The Marquette County Telephone company has begun work on the construction of its telephone system in Ishpeming. F. R. Marsh of Chicago will have charge of the construction work.

HINTON, W. VA.—The new telephone company consists of the following Directors: P. K. Litsinger, President; J. M. Ayers, Secretary; E. O. Prince, Treasurer; Directors, J. J. Swope, J. A. Oldfield, B. L. Hoge, P. K. Litsinger, H. Ewart, J. A. Parker, T. G. Swats.

BRITT, IA.—The Western Electric Telephone company of Britt, Hancock county has been formed. It proposes to operate a telephone line which shall extend through the counties of Cerro Gordo, Hancock, Kossuth, Palo Alto, Clay, O'Brien, Sioux, Lyon, Osceola, Dickinson, Emmet and Winnebago.

ELMIRA, N. Y.—The Susquehanna Telephone Company and the Metropolitan Telephone Company have been consolidated, and will be continued under the former title. Frank Zeller has been elected superintendent and Dr. W. W. Fletcher secretary. Dr. W. S. Mitchell has been elected treasurer.

CARTHAGE, MO.—The Carthage Electric Telephone Co. has filed articles of association, capital $5,000. Theo. J. Clark, Eliza C. Clark, Geo. E. Wheeler, Laura E. Wheeler and E. R. Wheeler, stockholders. T. J. Clark is president and treasurer, E. R. Wheeler, vice president, and Geo. Wheeler, superintendent and secretary.

RACINE, WIS.—A new telephone company has been established at Western Union Junction, which will operate a line between that place and Somers, Kenosha county, and will eventually extend to other towns in the two counties. The capital stock is $5,000 and the officers are: President, C. A. Brown; secretary, Frank Lingsweiler; treasurer, Dr. Stonebreaker.

HAMBURG, ARK.—Articles of incorporation of the Hamburg and Portland Telephone Company have been filed. The incorporators are: J. D. Pugh, Chas. M. Woodward, J. H. Pryor, T. R. Pugh and T. B. Savage. The capital stock of the corporation is $3,000, of which $1,810 is subscribed. The object of the company is the construction of a telephone line between Hamburg and Portland, in Ashley county, nearly twenty-five miles.

CLINTON, IA.—B. S. Price, general foreman of the Postal Telegraph Cable Company, has been selecting a route for a new telephone line between Dubuque and Muscatine. He says the company intends to establish a new line connecting river points from Dubuque south to St. Louis, with competing offices at Clinton, Davenport, Welton, Muscatine, Burlington, Fort Madison, Keokuk, Quincy, Hannibal and St. Louis.

OAKLAND, CAL.—A corporation known as the Commercial Telephone Company has filed articles with the County Recorder preparatory to doing business in Alameda County. The directors are E. R. Smith, Albert L. Stetson, J. D. Johnson, John W. Butler and S. P. Lunt. The capital stock is $100,000, divided into 1,000 shares of $100 each. It is estimated that the line will be a hundred miles long.

THE ELECTROTHERM: THE ELECTRIC HEATING PAD OF THE H. W. JOHNS COMPANY.

In putting on the market a new invention, the first consideration of the inventor is, naturally, how much grist it will bring to the mill, how many dollars there are in it. But when that point has once been agreeably assured, there is a good deal of extraneous satisfaction in the idea that every sale of the article invented is a piece of practical philanthropy that is certain to play a large part in reducing human suffering, and may even be instrumental in saving life itself. The H. W. Johns Company are to be congratulated on being in a position to undergo this experience, and the success which has attended the introduction of their new "Electrotherm," or electrical heating pad is as gratifying to the public as it is to themselves. The electrotherm is a flexible sheet or pad of asbestos. In the pad are embedded the heating wires, which receive current on connection with the socket of an electric lamp, or a battery. Practically, any degree of heat, say, from 130 to 220 deg. Fahr., can be produced, and maintained for any length of time, and where even a higher temperature is required, it can be attained by the use of additional covering. Such a device lends itself to innumerable uses; but in medical work it is simply invaluable. The hot bottle has always been a clumsy makeshift. It was the best the nurse could do, but it was lamentably inefficient, and often involved serious risks. At the critical point of a case, absolute freedom from disturbance often becomes as eminently essential to the patient as the maintenance of vital warmth and the necessary substitution of a fresh set of heating bottles was often attended with the greatest danger.

The slightest relaxation in watchfulness on the part of the nurse might cause serious burns, and there were always the factors of the varying sensitiveness of skin in different subjects, and the development of the latent heat of the bottles, to be guarded against. The Electrotherm overcomes all these difficulties. Heat of any degree, gentle or strong, can be imparted to the patient, and maintained without variation or disturbance for days, or weeks, if need be. If the effect of a poultice or moist heat is required the Electrotherm is applied over one or two thicknesses of wet flannel. Hospital doctors and nurses are most enthusiastic in its praise, and hardly less so are the many veterinary surgeons who have used it with great success in the treatment of numerous diseases of horses and cattle. The Electrotherm is made in several forms: as a pad 11 in. by 15, and ¼ in. thick, for general domestic or surgical use; as a foot warmer, in the shape of a pad covered with wickerwork; as a special collar, chest and back pad combined, covered with felt or rubber; rugs, blankets, mats for operating tables, sweating jackets, etc., and in fact, in any shape or size required. It is made for any voltage from 5 to 125 volts, and can be used with either direct or alternating current. The voltage required is printed on each article. The temperature is regulated by a switch newly patented by the H. W. Johns Company, the manipulation of which is perfectly simple and easy. The cost of maintaining a constant heat in the ordinary pad does not exceed one cent per hour, and a given number of pads will virtually give the service of nearly twice that number of hot water bottles.

THE "STANDARD" STORAGE BATTERY.

A NEW storage battery of which great things are expected, is about to be placed on the market, under the name of the "Standard." It is the invention of Mr. J. Hart Robertson, who was formerly identified with the writing telegraph, and Mr. J. Heron Crossman, of 50 Exchange Place, is largely interested in its patents. The "factory" plant is now open for inspection at 80 Pearl St., Brooklyn. The cells of this plant exhibit the ordinary characteristics of the Standard battery, but it is understood that a cell of extraordinary lightness, intended for traction and other work where the saving of weight is a desideratum, will be tested very shortly. The Standard factory cell is of the Planté type, 12 in. x 7½ x 4½. Its general appearance indicates solidity and serviceableness. Its 5 plates, the three inner of half-inch, and the two outer of one-quarter inch porous lead, and insulated by paraffined wood, are bolted together securely by hard rubber rods. The main feature of the cell is that by a simple and ingenious process any degree of porosity can be imparted to the lead at the moment of casting, and the claim of the inventor is that the battery will give as large an efficiency as any storage battery now on the market, with half the weight of cell, and at half the cost. In spite of the large amount of active surface secured in the plate, which is made from one piece of lead, it is very strong and serviceable. Buckling is absolutely provided against, and sulphating is reduced to the minimum. The internal resistance of the battery is exceptionally low, and the stated efficiency is very high. The figures of actual tests will shortly be available. An extended description of this invention must be reserved until after the public demonstration of its capabilities, which will be made during this week. For the present it may be said that it appears to possess many of the qualities which will lift the accumulator still higher in practicability for general work.

Society and Club Notes.

NORTH WESTERN ELECTRIC LIGHT ASSOCIATION.

The North Western Electric Light Association will hold their summer annual convention in Chicago, July 17, 18 and 19, headquarters at the Leland Hotel. Accommodations have been secured for exhibitors on the parlor floor, and arrangements for space can be made with Wm. Goltz, secretary of the Association, Milwaukee. Programme, July 17: Business meeting, 9 to 12; afternoon: Delegates will visit the plants of the Metropolitan Elevated R. R. and Chicago Edison Co. by special invitation. July 18: Business meeting, 9 to 12; afternoon: Special train to drainage Canal stopping at Sag and Lamont the two most interesting points on the work of the Canal up to date. For the evening the body of the house has been secured at the Columbia Theatre ("Merry World") and a topical song will be given containing references to the meeting and the delegates. July 19th.: Business meeting as before; delegates taken through the Boulevards, World's Fair grounds and back to the hotel. Mr. S. F. B. Morse is Chairman of the Entertainment Committee, a sufficient guarantee of good time being provided.

Married.

Mr. Charles B. Price, of the Pettingell Andrews Co., of Boston is at present receiving many congratulations from his numerous friends, on the occasion of his recent marriage to Miss M. A. Grosvenor of Peabody, Mass. Mr. and Mrs. Price will be at home to their friends at 245 Lafayette street, Salem, Mass., after the first of September. Mr. Price has been for many years connected with the Pettingell Andrews Co., has made for himself hosts of friends and is deservedly popular amongst the electrical trade, who all wish him every happiness.

Legal Notes.

COMPENSATION FOR USE OF ANOTHER CO.'S TRACKS.

The principles that have been laid down by Judge Valliant at St. Louis in his decision in the case of the Grand Avenue Railway Company against the Lindell Railway Company may serve as a guide hereafter in determining the compensation which one street car company should pay for the use of another's tracks. The cost of maintaining the portion of the road used by both companies must be divided equally between them, as also the taxes and the cost of sanding, sprinkling, salting and cleaning the track, the latter including freeing the road of obstructing snow. Half of 6 per cent. interest on the value of the portion used is also to be allowed the owner.

Reports of Companies.

NEW YORK EDISON CO. EARNINGS.

	1895.	1894.	Increase.
Gross, June........	$135,879.90	$123,193.30	$12,686.60
Net, June.........	69,869.51	58,888.54	10,980.97
Gross, 6 months..	947,445.06	825,338.43	122,106.63
Net, 6 months....	474,895.69	409,639.36	65,256.33

These figures include the earnings of the Manhattan and Harlem Companies.

SALE OF ELECTRIC ACCUMULATOR CO.'S STOCK.

The affairs of the Electrical Accumulator Company have been wound up in Philadelphia by a master's sale authorized by the United States Circuit Court in foreclosure proceedings instituted by the holders of the first mortgage of $500,000, and the principal assets of the company were 321,117 shares of the Electro-Dynamic Company's stock and 18,000 shares of stock of the Electric Storage Battery Company. Most of the assets were bid in by L. F. Potts, representing a syndicate interested in all three companies. The Electro-Dynamic stock, with a claim of $270,000 against the company, brought $125, and the bank accounts of the Accumulator Company $675. Nine hundred shares of the Electric Storage Battery stock brought $27.50 a share and the remainder $24 a share.

BIDS WANTED FOR A NEW HOSPITAL, WASHINGTON, D. C.

The Department of the Interior, Washington, D. C., is inviting proposals until 2 o'clock P. M. Monday, July 22nd, for furnishing and installing an electric light plant, at the Government Hospital for the Insane, near that city in accordance with the following official specifications. There are to be two plants, on the three-wire system, consisting each of a compound condensing engine, and a pair of compound wound self-regulating dynamos, with central station switch board of slate, ampere and volt meters, ampere shunts, knife switches, etc., complete for each plant. The aggregate output of the larger plant is to be 100 kilowatts, and of the smaller plant, 50 kilowatts, at 125 volts electro-motive force at the poles. The contractor to furnish superintendent in erecting and connecting all of the machinery, but the labor and freight will be furnished by the Institution.

The engines are to be compound, with two cylinders, opposite cranks, automatic cut-off governor, and to regulate within one and one-half per cent. between full load and no load, to run without thump or jar; to have heavy cast-iron foundation boxes, on brick or masonry foundation; to have approved sight feed oilers, proper drip pans, cast iron parallel lagging; to be fitted with counters and with indicators, connections and motions. The engines and driving wheels to be well balanced. The frames to be of cast iron, and heavy, the working part of wrought iron or steel, with factor of safety not less than five nor more than eight, with 100 pounds pressure on the H. P. piston. Working parts to be polished. The engines may be either horizontal or vertical, and they may be either directly connected or belted with four strand manilla ropes, if horizontal, the cylinder of the large engine to be about 13 and 20 1-2 inches in diameter, with a stroke of piston of 15 inches; to make 265 revolutions a minute; to have two rope wheels, each wheel having eleven (11) grooves for three-fourth inch diameter ropes. A templet for the grooves will be furnished to the contractor. The diameter of the rope wheels to be 74 inches on the pitch line. A 5-inch Stratton separator with a No. 2 Baird steam trap to be furnished for the steam pipe.

The smaller engine if horizontal is to have steam cylinders about 10¼ and 16¼ inches in diameter respectively, and 12 inches stroke of piston, and to make 285 revolutions a minute. To have two rope wheels 74 inches diameter on the pitch line, scored six (6) ropes each; ropes and grooves to be the same as on the larger engine. A three and one-half inch Stratton separator, with a No. 1 Baird trap to be provided for the steam pipes. The design, workmanship, and finish of the engines to be equal to that of the Armington and Sims engines.

There must be a satisfactory jet condenser and air-pump for each engine; the air-pump for the large engine to have ten inch steam cylinder 12 inch water cylinder, by a fourteen inch stroke; for the small engine the air pump will have 7 inch steam end, 9 inch water end, and 12 inch stroke of pistons; to have brass lined water end, brass water pistons, guards and springs and rubber valves. Air pumps and condensers, to be equal in all respects to the Davidson.

The dynamos are to be in pairs, direct current, and for the three wire system. They are to be compound wound, self-regulating, capable of exerting a constant pressure of 125 volts at the poles. Under these conditions the larger pair shall have a capacity of 1000 amperes, and the small pair 500 amperes. Approved regulators for the shunt circuit are to be supplied. The commercial efficiency of the dynamos is to equal eighty per cent. The winding of neither armature nor field to heat more than 60 degrees Fahr. above the temperature of the room, at full load. To be insulated electrically from their bed-plates; commutator bars to be of hard copper, insulated with mica, not less than one and one-half inches deep. Armature to have self-lubricating bearings, and with relatively large surface. Brushes to be of approved kind, easy of adjustment, and with abundant bearing surface.

The larger pair of dynamos is to equal in all respects two Edison No. 32, and to have rope wheels 30 inches, and the smaller ones to equal a pair of Edison No. 12, central station switch board and dynamos, with rope wheels seventeen and three-fourths inches diameter on pitch line, in lieu of belt pulleys.

Tests. The larger engine must be able to indicate 200 H. P. the smaller engine 100 H. P., with 100 pounds pressure in the boiler, and 25 inches of vacuum in the condenser. The insulation of the dynamos, conductors, and switch-boards not to be less than 500,000 ohms.

There will be provided and fitted one spare armature for each size of dynamo, and a spare set of crank pins, and cross-head brasses to be for each engine.

Alternate bids on vertical engines directly connected will be considered, provided the cranks are opposite, the steam cylinders as close together as practicable, and the engines and dynamos are equal in all other respects to the above specified plants.

All proposals must be in duplicate, addressed to the Secretary of the Interior, Washington, D. C., sealed, and endorsed on the envelope, "Proposal for Electric Light Plant."

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 2, 1895.

Alarms and Signals:—

Block Signal for Railways, W. G. Roome, Jersey City, N. J., 541,949. Filed April 28, 1893.

Police Patrol Signal, E. Brombacher, Buffalo, N. Y., 542,074. Filed Nov. 26, 1894.

Provides the box with simple means whereby the fast and slow call button can be shifted from one position to the other under all circumstances without the necessity of opening the door of the box.

Signaling, D L. V. Browne, Denver, Col., 542,142. Filed Sept. 12, 1894.

Means for signaling from the moving buckets or cages of mining or similar shafts from elevator cars.

Conductors, Conduits and Insulators:—

Manufacture of Electrical Conductors, L. W. Downes, Providence, R. I., 541,931. Filed April 2, 1895.

An insulated electrical conductor comprising a wire, a fine fibrous covering coated with a film of rubber, a compact winding of asbestos fiber saturated with soluble glass, and an exterior braided asbestos covering coated with fire-proof cement.

Apparatus for Manufacture of Wire, R. D. Sanders, Eastbourne, Eng., 541,986 Filed Sept. 20, 1894.

Claim:—In an apparatus for the manufacture of wire by electro-deposition the combination with a non-metallic cylinder having a spiral or suitable groove cut or formed therein, of a wire strip inserted or laid at the bottom of the said groove, and the pins and conductor in electrical communication with such wire or strip.

Electric Wire Joint, A. Gartner, Newark, N. J., 541,998. Filed May 24, 1895.

A wire joint consisting of a tube, provided with a longitudinally and spirally arranged slot, said tube being adapted to be twisted with and around the inclosed wires.

Dynamos and Motors:—

Dynamo Electric Machine, T. H. Hicks, Detroit, Mich., 541,854. Filed Aug. 29, 1894.

Relates to a machine having a double armature circuit intended for three-wire system, but each armature being independent of the other.

Commutator Brush, H. B. Collins, Fulton, N. Y., 541,919. Filed Jan. 26, 1895.

Details of construction.

Electrometallurgy:—

Electrolytic Process and Apparatus, L. P. Hulin, Modane, France, 542,057. Filed Dec. 19, 1894.

Consists in effecting the electrolysis of a suitable haloid salt of an alkali or alkali earth metal when in a state of igneous fusion, by means of two anodes, one of carbon, and the other formed of the heavy metal to be alloyed.

Galvanic Batteries:—

Galvanic Battery, R. W. Gordon, Boston, Mass., 542,049. Filed Jan. 31, 1895.

The positive and negative elements and the depolarizing agent are arranged to obtain the greatest possible output of current with a minimum deterioration caused by the action of the battery.

Lamps and Appurtenances:—

Incandescent Electric Lamp, R. Greer, Westbrook, Me., 541,929. Filed Nov. 10, 1894.

Consists in placing wholly within a receiver upon suitable supports a glass bulb open at its lower end, and then inserting into the receiver a plug consisting of a filament and its support the base of which is encircled with elastic material, then closing the receiver and exhausting the air therefrom, and then forcing the plug into the glass bulb.

Safety Device for Handling Electric Arc Lamps, E. P. Snowden, St. Joseph, Mo., 542,210. Filed Mch. 23, 1895.

Railways and Appliances:

Rail Bond, P. Cunningham, New Bedford, Mass., 541,838. Filed Apl. 1, 1895.

Claim:—The combination with the rails of an electric railway, of a rail bond comprising eyeleted pins or rods inserted through holes in the rails and split or divided as described, and a tie wire inserted into the eyes of the eyeleted rods and secured therein.

Trolley Wire Clip, F. W. Haeusgen, Buffalo, N. Y., 541,969. Filed Oct. 9, 1894.

Trolley Restoring Attachment, W. D. McDaniel, Philadelphia, Pa., 542,002. Filed Oct. 29, 1894.

The restoring wheel has a spiral groove.

Electric Locomotive, T. E. Adams, Cleveland, Ohio, 542,086. Filed Oct. 3, 1894

Means for flexibly supporting the motor on the axles of the car independently of the truck-frame.

Conduit Electric Railway, L. C. Pressley, San Francisco, Cal., 542,105. Filed Feb. 18, 1895.

The car operates switches admitting current to insulated sections.

Conduit Electric Railway, L. R. & A. H. Lavalle, Holyoke, Mass., 542,164. Filed Mch. 17, 1894.

Employs a continuous insulated conductor connected in a series of blocks which are cut in and out by the passing car.

Switches, Cut-Outs, etc.:—

Automatic Safety Device for Electric Circuits, L G. Rowand, Camden, N. J., 542,030. Filed Feb. 6. 1895.

Consists of a switch in shunt with the main circuit, the resistances of the shunt circuit being greater than the resistance of the line circuit under normal conditions.

Telegraphs:—

Automatic Telegraphy, P. B. Delany, So. Orange, N. J., 541,967. Filed Apl. 3, 1895.

Forms one of the characters, either the dot or the dash, and preferably the dash, of a greater width transverse to the receiving ribbon than the other character.

Duplex and Diplex Telegraphy, M. M. Davis, Brooklyn, N. Y., 541,994. Filed Apl. 18, 1895.

Specially useful in a pole-changing transmitter where the succession of currents to line is abruptly changed from a maximum positive to a maximum negative.

Telephones:—

Telephone System, A. S. Hibbard, Chicago, Ill., 542,052. Filed Feb. 21, 1895.

Relates to a divided switchboard system.

Annunciator Circuit for Telephone Switchboards, C. E. Scribner, Chicago, Ill., 542,066. Filed Nov. 12, 1894.

The annunciator is wound differentially so as to avoid impedance when included in the talking circuit.

Magneto Electric Telephony, E. S. Halsey, So. Evanston, Ill., 542,191. Filed April 20, 1894.

The design is to maintain the magnetic flux practically constant and to effect the electric induction by variably diverting the current through two paths at some part of the magnetic circuit.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 9, 1895.

Alarms and Signals:—

Railway Block Signal System, G. M. Brown, Galesburg, Ill., 542,550. Filed May 4, 1895.

Distribution:—

Transformer for Alternating Current Systems, E. Thomson, Swampscott, Mass., 542,295. Filed March 6, 1895.

A transformer for alternating currents, comprising two laminated cores, primary coils wound upon one of the cores, secondary coils upon the other, and links of copper connecting the cores and adjacent to the primary and secondary coils, the plates being connected to earth.

Electric Lighting System and Dynamo Therefor, M. Moskowitz, Newark, N. J., 542,487. Filed May 11, 1895

A railway car lighting system in which the dynamo has a differential series coil.

Galvanic Batteries:—

Electric Battery and Application Thereof to Medicinal Purposes, S. R. Beckwith, Orange, N. J., 542,459. Filed April 3, 1895.

Lamps and Appurtenances:—

Arc Light Support, B. Pickering, Dayton, Ohio, 542,279. Filed Nov. 15, 1890.

Details of construction.

Electric Arc Lamp, S. E. Nutting, Oak Park, Ill, 542,490. Filed Sept. 8, 1894.

The feed of the carbons is controlled by the action produced by the expansibleness of certain parts due to heat caused by the resistance to the current of electricity passing through that portion of the circuit.

Electric Arc Lamp, F. M., E. S. and H. F. Hildebrandt, Baltimore, Md, 542,589. Filed Dec. 27, 1893.

The arc is inclosed in a small transparent air tight casing provided in its upper end with a valve.

Measurement:—

Electric Meter, F. P. Cox, Lynn, Mass, 542,240. Filed Feb. 15, 1895.

Relates to recording wattmeters of the Thomson type adapted to constant current circuits.

Electrical Measuring Instrument, F. Holden, Schenectady, N. Y., 542,258. Filed Jan. 22, 1895

A field coil for an electric measuring instrument, composed of a serrated strip of conducting material having registering perforations through which the inner terminal of the coil is passed.

Electric Alarm Gauge, W. H. Brandt, Troy, N. Y., 542,406. Filed Feb. 23, 1894.

Details of construction.

Miscellaneous:—

Automatic Electric Weighing Scale, C. F. Wood, Richmond, Va., 11,508, Reissued. Filed June 20, 1893.

Weighs the requisite amount of seeds and deposits them in paper bags.

Electroprotective System for Locks, M. Martin, Malden, Mass., 542,368. Filed Oct. 4, 1894.

The testing part of the system is employed in conjunction with the lock whereby the person locking is required to make the test before the lock can be operated.

Electric Bath Apparatus, W. E. Golden, Auburndale, Ohio, 542,471. Filed Mch. 5, 1895.

Medical Electrode, A. P. Van Tuyl, Jr., Brooklyn, N. Y., 542,506. Filed May 15, 1895.

Electrically Controlled Motor, G. L. Thomas, Brooklyn, N. Y., 542,548. Filed Apl. 25, 1895.

The pressure of a fluid within an expansible chamber serves to set in motion an actuating rod.

Railways and Appliances:—

Trolley Breaker, H. P. Ball & C. A. Lieb, New York, 542,223. Filed Aug. 8, 1894.

Details of construction.

Underground Trolley, L. Binns, Philadelphia, Pa., 542,484. Filed Apl. 11, 1894.

Consists of a duct, a conducting-rail in the duct and connected with the source of electricity-supply, and a frame hinged on the under side of the vehicle and carrying a trolley-pulley.

Electric Railway System, R. B. Wilson, Cincinnati, Ohio, 542,512. Filed Jan. 2, 1894.

Details relating to a sectional system with insulated main conductors, and section magnets.

Trolley Finder, C. C. Lynde, Buffalo, N. Y., 542,591. Filed Nov. 28, 1894.

Telephones:—

Telephone Switchboard, J. F. Gilliland, Adrian, Mich., 542,249. Filed Oct. 26, 1894.

The switchboard is provided with a number of pairs of plates running parallel to each other and insulated from each other and unprovided with any circuit connections, the connections between two telephone lines being produced by pushing the plugs of the lines over the plates of the same pair.

Multiple Switchboard for Telephone Exchanges, M. G. Kellogg, Chicago, Ill., 542,262. Filed Dec. 21, 1889.

Relates to the construction of a switch plug and switch.

Telephone Transmitter, C. C. Hughes, Baltimore, Md., 542,444. Filed Sept. 12, 1894.

A multiple electrode transmitter in which the electrode has a cavity whose sections on planes perpendicular to the direction of motion are arcs of circles of gradually varying radii.

MANHEIM, PA.—A charter has been granted to the Manheim Light, Heat & Power Company; capital stock, $20,000.00. The directors are: Vance C. McCormick, Harry B. McCormick, Harrisburg; F. E. Bailey, Philadelphia; L. U. Bailey, Dillsburg; Robert A. Carl, Harrisburg. The plant will be built at once by F. E. Bailey & Co., of Philadelphia, and will consist of a combination steam and water power plant to drive the generators. The streets will be lit up and lights and power will be furnished to Manheim and vicinity.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE GRUTTING ELECTRIC SOLDERING IRON AND CURLING IRON HEATER.

GRADUALLY but surely the cleanliness and handiness of electric heating appliances is bringing this class of apparatus forward not only in manufacturing establishments but equally so in the domain of domestic economy. The ease and rapidity with which electric heating can be effected are additional strong points in its favor, and the accompanying engravings show two pieces of

FIG. 1.—THE GRUTTING ELECTRIC SOLDERING IRON.

apparatus which embody several novel features in this class of work, and which are the product of the Heilbron Brass Works, of St. Paul, Minn.

Fig. 2 illustrates their Grutting electric curling iron heater. As will be seen, the heater is suspended from an ordinary electric light socket, thus avoiding possible damage to furniture, as would be the case if the apparatus were mounted on a stand set on a table or stand. This mode of applying the apparatus also avoids the necessity of stringing a long flexible cord to the table, and hence makes it most convenient when travelling. In order to obtain the highest economy, the heating resistance is inserted in the curling tongs; this applies the heat in the right place, and when the tongs are ready for use, which takes about half a minute, the current is gradually reduced by means of a compensating resistance in the housing. This prevents overheating and brings the expense of running, down to a minimum.

The Grutting electric soldering iron, shown in Fig. 1, is

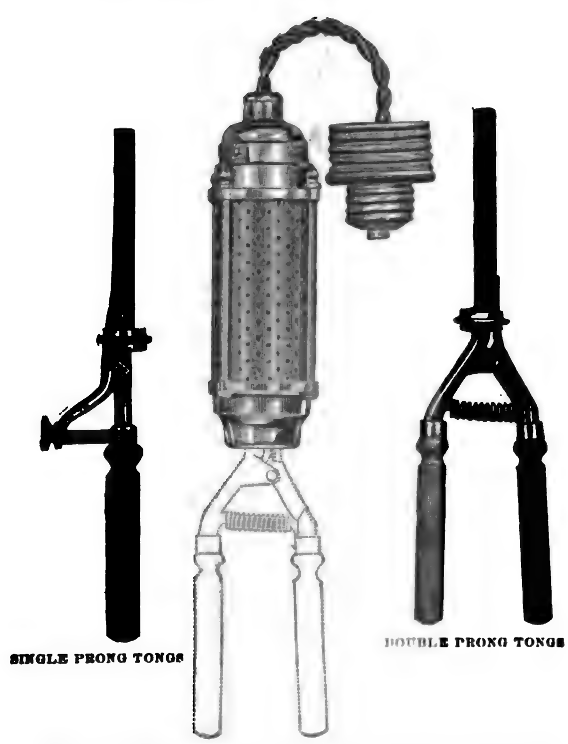

FIG. 2.—THE GRUTTING ELECTRIC CURLING IRON.

designed to afford a hot iron at all times. The heater is enclosed air-tight in a cast iron cylinder, and is made of an infusible material of which carbon is the principal constituent. Both the curling and the soldering iron are designed for 55 and 110 volt circuits. The soldering iron is made in three sizes, 1, $1\frac{1}{4}$ and $1\frac{3}{8}$ diameter, and provided with interchangeable copper tips, so that when one becomes worn another can be substituted at slight cost.

TESTS OF OKONITE BY DR. FLEMING.

The excellent qualities of Okonite have been so long known that it seems hardly necessary to adduce any more proofs of its high character as an insulating material. Nevertheless, consumers will be glad to learn that the high standard set for itself by the Okonite Co. is being maintained. This is fully established in the reports recently made by Dr. J. A. Fleming, the well-known author and Professor of Electrical Engineering in University College, London. We give below extracts from two reports.

Under date of December, 1894, Dr. Fleming reports:

The cables sent to me were in large coils of about half mile lengths, and came just as they were forwarded by the makers. * *

I have found in this Okonite Cable a very marked increase of insulation resistance with time of charging, and have, therefore, given all the results in the form of curves on a chart appended to this report, in which the insulation resistance of the samples is shown in megohms per mile of cable after one to five minutes' charging. * * *

My opinion of these cables is, therefore, that the Okonite material is a remarkably good insulator, and that the samples of Okonite Cable submitted to me represent a very high degree of excellence in the manufacture of insulated cable. I do not lay much stress on mere megohms per mile in a cable. The real practical test of a cable is the electrical pressure it will withstand after prolonged soaking in water, and such general rough usage as the the cable will experience in actual handling. In order to test the mechanical toughness of the Okonite material, I bent and kinked several samples at such sharp angles as to break the copper strand inside the Okonite insulation. This mechanical toughness combined with its flexibility is a great point in its favor.

I consider that this Okonite Cable is a very excellent and high class cable for all outdoor, overhead, or underground electrical work, with high electric pressures, whether alternating or continuous.

I regard it also as an excellent material for indoor wiring work, in cases in which the conductors are necessarily exposed to moisture, and under conditions in which a very large factor of safety must be employed. The standard copper conductor being tinned and twisted was not in a form suitable for a very accurate test of the copper conductivity, but the figures given for the resistance per mile of the Coils A, B and C, show that the copper employed is not less than 98% conductivity in all probability.

I consider that the behavior of these samples of Okonite cables places it in the front rank as a class of cable for electric lighting and transmission work.

Under date of Feb. 15, 1895, Dr. Fleming reports:

The next question to which I have directed my attention is the power of the Okonite material to withstand the action of chemical agents. For this purpose five samples of the Okonite cables were put to soak on January 12th, 1895, in the following chemical solutions:

(a) was put into strong Salt and Water.
(b) " " " Paraffin Oil.
(c) " " " Linseed Oil.
(d) " " " Caustic Soda Solution.
(e) " " " Dilute Sulphuric Acid, 1:10 or battery acid.

These samples were left soaking in these solutions until February 15, or for 34 days. They were then tested for insulation at 100 volts and found to be in excellent condition.

The samples were then submitted to the electric pressure test, the pressure being taken up to 3,360 volts by the use of an alternating current having a mean pressure of 2,400 volts, and all of these showed no signs of failure when exposed to this pressure for five minutes.

This forms an exceedingly severe test of the high insulating quality of Okonite, that after this soaking in oils, brine, acids and alkali for more than a month all the samples withstood 2,400 alternating pressure perfectly.

I have no hesitation, therefore, in saying that I think the Okonite insulation is a remarkably fine insulating material and one which by its electrical and mechanical qualities is well fitted for use in electric cables for high or low pressures. I have not found that the severe cold of the last month has rendered it at all brittle.

ELECTRICAL DISINFECTION PLANT FOR PHILADELPHIA.

A contract for the erection of an electrical disinfecting plant has been awarded by the Philadelphia Board of Health to the Excelsior Electric Company, with a bid of $2537. Director Beitler was requested to appoint an assistant disinfector to meet the demands of the service.

MR. WM. HUBBARD, so long and so well known in the field of telephony has withdrawn from the firm of Wm. Hubbard and Enyart, dealers in telephonic apparatus, and has taken the agency for the Gilliland Electric Co. of Adrian, Mich., for the State of Illinois. He will have his agency at Elgin, Ill., and will now devote his energies to pushing the Gilliland magneto telephones.

CARPENTER ENAMEL RHEOSTAT CO.

The Carpenter Enamel Rheostat Co. is one of the very few electrical concerns whose business has steadily increased throughout the recent business depression and which has paid regular dividends to its stockholders. The Carpenter Company has already paid 5 ½% on its capital stock during the present year, and its prospects are extremely bright. The Carpenter Co. is now filling orders for its electric soldering irons, curling irons, and disc heaters. Mr. Carpenter is giving personal attention to the introduction of these goods which are meeting with a very ready sale. H. Ward Leonard sailed for Europe on the "Paris," July 10th, to be gone several months. Mr. Leonard will represent several interests while abroad and will be able to accept commissions from parties in the United States desiring investigation of electrical matters on the other side of the water. His address will be care of Low's Exchange, 57 Charing Cross, London, E. C., England.

A PROMISING INVESTMENT.

The attention of practical investors and central station men or electric railway managers is called to the announcement of "C. K." in our advertising pages this week, relative to the opportunity of securing control of a combination plant. The station in question has been illustrated and described in THE ELECTRICAL ENGINEER, and we are of opinion that an excellent chance is presented to secure a property, the personal management of which should yield handsome returns. The references are of the best, and the closest inspection of the property is invited.

D'OLIER ELECTRIC CO.

The D'Olier Electric Co. has recently been formed at Philadelphia, with headquarters at 129 South Eleventh street. The members of the concern are W. L. D'Olier and Henry D'Olier, Jr. The company will make a specialty of electrical engineering and construction, as well as of repair work, and are ready to instal either a lighting plant or a telephone line or a call bell circuit. They will also undertake the care and maintenance of interior work and services for a small yearly fee.

WESTERN NOTES.

THE WALKER MFG. CO., Cleveland, O., through their Chicago representatives, the Messrs. Kohler Bros., have received the following order for the Sheboygan, Wis., Consolidated Street Railway Co., one 200 K. W. generator and 12 motors to be placed on six cars.

THE WESTERN TELEPHONE CONSTRUCTION CO. report the following sales: Chillicothe, O., 200 telephones installed, 100 more ordered. These are fully equipped with fire alarm telephone apparatus as well as being for commercial use; 100 telephones to Menominee, Wis. The Interior Department, Washington, are putting in telephones in addition to those already installed.

CHAS. E. GREGORY CO. have just issued the 1895 edition of their very neat and handy Electrical Telephone Directory. This little book fits nicely in the pocket, and as it contains the names, addresses and telephone numbers of all those who are interested in electrical matters in Chicago, as well as a list of the clubs and hotels in the city and several blank pages for notes, it is one thing that the electrical man cannot afford to be without.

THE ELECTRIC APPLIANCE COMPANY are securing some very pleasing results from the Upton arc lamps and have received a number of compliments. The direct and alternating constant current lamps appear to meet every requirement, and the regular series arc lamp is apparently filling the demand for a first-class series arc lamp at a low price. They have already placed a number of large orders for all their styles.

ATHENS, O.—Through the efforts of the eastern office of the Franklin Electric Co. the contract for a lighting plant at the Athens State Hospital, Athens, O., has been awarded to them. The plant will consist of two 60-horse power Russell Engines, 1–20 horse power Russell Engine, two multipolar 35 kilowatt Westinghouse dynamos and 1–15 kilowatt Westinghouse. 1200 lights will be used throughout the building and 6 arc lights on the grounds. The plant is to be completed on or before Nov. 1st, and the contract covers the complete installation.

METROPOLITAN ELECTRIC CO.—Business with the Metropolitan Electric Company, 186–188 Fifth Avenue, Chicago, in the fan motor line is very largely on the increase; they are doing a better business in this line than they have ever done before. Their Metropolitan incandescent lamp is giving excellent satisfaction and they are making large sales constantly. They call attention to the great reduction which they have made in the price of 12-inch alternating fan motors. There are but a few left, and orders should be sent in at once.

MR. C. G. ARMSTRONG has obtained the contract for the power plant of the Milwaukee Harvester Co., Milwaukee, Wis., which will be ready to start up on August 15th. This will be the first two-phase isolated plant in the West, and will consist of one 75 K. W. Westinghouse generator, 7,200 alternations per minute, 400 volts, and run at a maximum speed of 800 revolutions. The engine used will be a 110 H. P. Ball & Wood. There will be six Westinghouse motors used for the motive power of the factory, of the following sizes: One 30 H. P., one 20 H. P., one 15 H. P., one 10 H. P., two 7½ H. P.

THE RACINE, WIS., HARDWARE CO., have very good reason to feel quite jubilant. They are increasing their business all the time, and are running double shift at their factory. At the same time they are prepared for any emergency as the following goes to show. A short time ago their energetic Chicago representative, Mr. W. F. Parrish, Jr., received an order for one of their medium sized vertical engines at 4 P. M. The order was immediately telephoned to the works, where the engine was tested, boxed, delivered to the railway Co., arrived in Chicago at 5 A. M. the next morning and was delivered as soon as the purchasers were ready to receive it. This Co. have recently made the following sales: 8 outfits of marine engines and boilers to Buffalo, N. Y.; 2 marine engines to New Jersey, and quite a number to the western states. They will be pleased to send one of their handsome catalogues, with blue prints, and information to anyone interested in the class of machinery they manufacture.

PHILADELPHIA NOTES.

THE STANDARD UNDERGROUND CABLE CO., Pittsburgh, are building a large new brick warehouse. Business is good with them.

MR. CHAS. WIRT, formerly at 56 Fifth Ave., Chicago, has removed to Philadelphia, where his address is Ludlow, cor. 31st St. Queen & Co. have secured the right to the Wirt switchboard instruments and will manufacture these instruments in the future. Mr. Wirt is manufacturing his "non-sparking" dynamo brush and will shortly bring out a new brush intended for motors and dynamos, which are required to run with almost no attention.

PENN ELEVATOR CO., Bloomsburg, Pa., whose electric elevator was illustrated in THE ELECTRICAL ENGINEER last week has been in existence only a short time, but has already several plants in operation in different cities. It is making a specialty of the electric elevator, and is obtaining good results. It has an electrical plant in its own shops, whereby all elevators are tested before shipment. It is thus able to guarantee its customers excellent work. The officers of the company are Paul E. Wirt, president; L. E. Waller, vice-president; P. S. Harman, treasurer: C. C. Peacock, secretary and H. G. Sherwood, manager. The Philadelphia office is at 43 North Seventh street.

NEW YORK NOTES.

THE INTERIOR CONDUIT & INSULATION CO. are very busy equipping summer theatres with Lundell fans.

ATLANTIC CITY, N. J.—The Atlantic Electric Light & Power Co. has, Supt. Fowden states, a total capacity now of no less than 8,500 incandescents and 620 arcs. It has just put in a new Kensington engine to run three dynamos, a new Buckeye, Sturtevant blower, and some new General Electric dynamos.

MR. S. F. B. MORSE, the Kerite man of Chicago, paid New York a visit this week, and received a hearty welcome from his numerous friends in this city. Mr. Morse is chairman of the entertainment committee of the North Western Electric Light Association, which has its convention at the Leland House, Chicago, on July 17, 18, 19, and will be glad to see a large contingent from the East in Chicago at that time.

MR. C. M. MAXWELL, formerly of Portland, and now of San Francisco, who has been for many years prominently identified with electrical work, has recently severed his connection with the local Edison Company in San Francisco in order to devote himself to several important interests which have been placed in his hands. Mr. Maxwell who was in New York last week for the purpose of closing arrangements for the representation of some leading New York houses on the Pacific Coast, has left for home.

NEW ENGLAND NOTES.

MR. A. G. LAIDLAW for many years in the electrical business in Boston, has accepted a position as superintendent for the Philadelphia Electrical Equipment Co., of Philadelphia, Pa. Mr. Laidlaw has been connected with the New England Electrical Co., the General Electric Co., and has recently been with Frank Ridlon & Co., and leaves with the best wishes of his late employers.

THE
Electrical Engineer.

Vol. XX. JULY 24, 1895. No. 377.

CANADIAN WATER POWER SCHEMES AT NIAGARA, MONTREAL AND TORONTO.

NOW that the wheels of the Niagara Power Company have been actually set in motion on the American side at Niagara Falls, and the success of the undertaking is no longer a matter of conjecture, plans are rapidly maturing for the utilization of other water powers. Besides the work shortly to be begun on the Canadian side of the

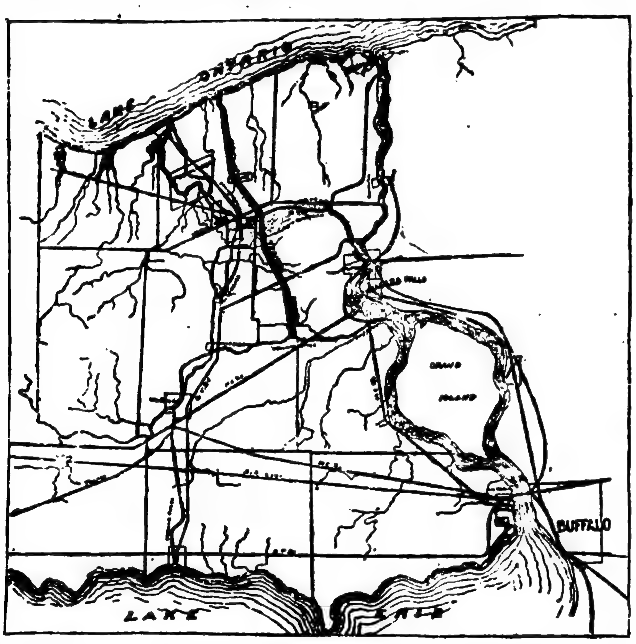

FIG. 1.—PROPOSED POWER CANAL FOR WELLAND POWER AND SUPPLY CANAL COMPANY.

Horse Shoe Falls, the plans of which were illustrated in THE ELECTRICAL ENGINEER, issue of June 26, a number of other water powers are proposed for utilization in Canada, some involving powers even greater than that on the American side.

The first of these to claim attention owing to its proximity to Niagara is the scheme of the Welland Power & Supply Co. (Limited) which was incorporated at the last session of the Dominion Parliament, and whose aim is not only the utilization of power but also to supply water to irrigate the peninsular fruit belt. The charter of the company permits it to draw unlimited water from the Niagara River. The company is empowered to deepen or widen the Chippawa Creek from its mouth to the point of intersection of the proposed canal, four and one half miles west, and it is said there is nothing in the charter to prevent the company from diverting the course of the Niagara River to Thorold, Ont.

As shown in the accompanying map, Fig. 1, the company propose to take the water through a widened and deepened channel in the mouth of the Welland River, and at a distance of 4½ miles from the Niagara River. The water is to be taken through a surface canal 100 feet wide at the bottom, 150 feet wide at the top, and 15 feet deep, and will be carried by one level open cut through clay to the escarpment near the town of Thorold, a distance of about 6½ miles, to the brow of a mountain, with a drop of only 10 feet from the level of Lake Erie, giving an available fall of 320 feet to the level of Lake Ontario. It is proposed to locate the first turbines 150 feet below and then to carry the water by a series of falls, each generating power, to an open canal or raceway emptying into Lake Ontario, 6½ miles away. The profile of the course taken by the water is shown in the engraving, Fig. 2. On the mountain top at Thorold it is proposed to build a lateral canal long enough to feed 60 turbines, each of 5,000 H. P. capacity. Mr. Chas. A. Hesson, collector of inland revenue at St. Catharines, Ont., one of the prime movers in the company, claims that the proposed plan will make it possible to deliver power at Fort Erie, Ont., at the very door of Buffalo, for $6 per horse power per annum.

The enterprising city of Toronto is also to be the scene of a power transmission scheme with the source of power barely beyond the city limits. The plan to be adopted is illustrated in the accompanying map, Fig. 3. The Georgian Bay Ship Canal & Power Co. is about to begin operations in the Humber Valley about 1½ miles above the mouth of the Humber River. At Baby's Point, on the farm of Mr. Frank Baby, a dam will be thrown across the river, which will form a great reservoir, the fall from which will be utilized. The dam will be 140 feet high; length at base, 444 ft.; length at summit, 838 feet; thickness at base, 80 feet; thickness at summit, 20 feet. With the erection of the dam at the point indicated, a lake about six miles in length, with an average width of one mile will be formed. No other embankment will be required. Some idea of the magnitude of this great reservoir may be gathered from the fact that a six months'

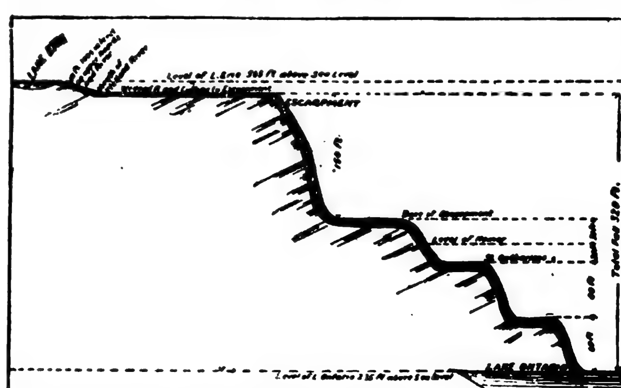

FIG. 2.—PROFILE OF COURSE TAKEN BY WATER, PROPOSED POWER CANAL.

supply can be taken from it during the dry season without reducing the level below the point of efficiency (120 feet).

According to the report of the engineer, Mr. Kivas Tully, C. E., the Humber drains 562 square miles, the surplus water from the watershed amounting to 23 billion cubic feet annually, or averaging over 400 million gallons daily. This water, by the construction of dams at intervals along

the basin, can be used at various heads so as to secure a total fall of over 450 feet on the average, and the energy thus derived is capable of developing 91,459 horsepower, gross, for ten hours each day, or 68,595 electrical horse-power, net. If section "A" alone were built, a head of over 140 ft. would be had on the first dam, and with the daily average supply of water this head would give 10,668 horse-power immediately. Every dam and reservoir constructed up stream would add to this, so that out of the Humber alone over 68,595 horse-power could be taken ten hours daily. The addition of the Lake Simcoe and Black River waters to this would increase the electrical horse-power per ten-hour day by 250,974, or a total of 319,569 horse-power.

The 10,668 H. P. immediately available would be sufficient to generate current to supply all the power required in West Toronto Junction and the western part of the city and move all the electric cars in the city. About $350,000 will be required to cover the land damages and cost of properties appropriated. The construction of bridges, the deviation of roads and the building of the dam will not exceed $375,000 more, or a total for the whole work of $725,000. This is said to be a liberal outside estimate. To this will have to be added the cost of the power house and plant.

Besides the enterprises just described we may add another which has long been contemplated, but which has only recently taken definite shape, and that is the utilization of the Lachine Rapids, about 5 miles above Montreal.

The plan which it is proposed to follow is illustrated in Fig. 4. At the upper end of the dam, projecting above the water, is the triangular ice-guard protecting the timber

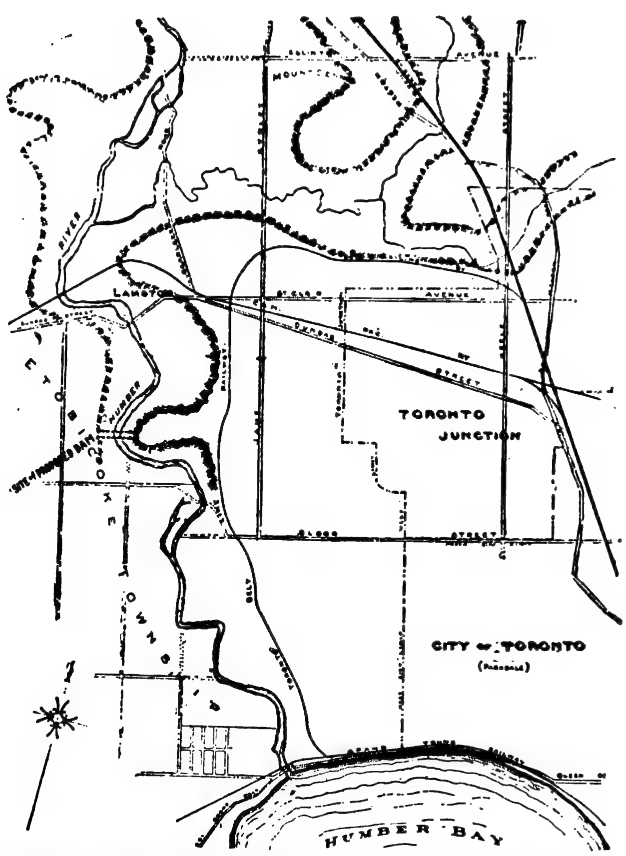

FIG. 3.—PLAN FOR UTILIZING POWER OF HUMBER RIVER, TORONTO.

dam. The dam from this for about 1000 feet will always be under water, and it is over this over-fall that it is proposed to discharge the floating ice. Below this over-fall for 1800 feet the dam rises somewhat higher and will only overflow at high water, its object being to control the head or keep the power constant. From this point to the main dam the crib work will be raised high above the greatest known flood, and from the main dam down stream it will be continued some distance, but at a lower level to form an ice-guard and prevent the ice entering into the tail race.

To utilize the power thus formed a dam will be thrown across at the foot and will consist of isolated piers somewhat resembling bridge piers, and between these piers will be placed wheels and shafting. On these piers the

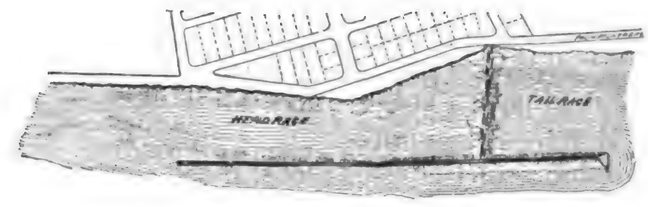

FIG. 4.—PLAN FOR UTILIZING POWER OF THE LACHINE RAPIDS, NEAR MONTREAL.

dynamo houses, shaft sheds and bridge will be constructed. From Lake St. Louis to the harbor of Montreal there is a fall of some forty-four feet; of this the Company utilize only eight feet. They intend to put in sixty-six 61-inch turbine wheels, which under an 8-foot head, should give 120 horse power each, or a total of 7920 horse power. Tenders for the construction of the work have already been called for.

THE EFFICIENCY OF HEATERS.

The German Hygienic Association, offers a prize of $1200 for a research essay on the heat given out by heaters. The programme is: "The heat given out in heating installations by heaters in their various forms and modes of use is to be ascertained. The investigations are to be described in detail in respect to the arrangement of the heaters, the nature of the heating agents and the observations made; and they are to be illustrated by drawings. The heating values obtained are to be stated in units of heat given off per hour per unit of surface. In the case of heat given out to air, the investigations must be conducted with currents of air at speeds as different as possible. The heaters are to be described in detail as regards form and measurement, and the relation of their heating efficiency to their weight is also to be ascertained." Essays to be written in German, with a motto and sealed envelope, and sent to Prof. Konrad Hartmann, Charlottenburg, Fasanenstrasse 18, before July 1, 1896. The essay will remain the property of the successful competitor, but he must publish it within six months, and give the prize offerers 300 copies gratuitously. The prize may be divided or withheld.

ELECTRIC LIGHTING AT BERLIN.

In the annual report of the Berlin Town Council on the administration of the municipal gasworks, some interesting figures are given in regard to electric lighting in Berlin. There are in all 185 street arc lamps, 71 of which are alight all night, the remainder only burning up to midnight. For private purposes there are 9,932 arc lamps, 200,474 glow lamps, and 667 motors and apparatus. Of these, 4,259 arc and 79,212 glow lamps are supplied by isolated plants, of which 251 are driven by steam and 97 by gas engines. Current for the remainder is supplied by the Berlin Electricity Works. The increase of the lamp connections over those connected at the end of the previous year (1893) was 16·23 per cent.

REPAIRING UNDERGROUND TELEGRAPH CABLES IN WEST AFRICA.—A UNIQUE ENGINEERING EXPERIENCE.

NOT the least important part of an engineer's equipment for his work is the ability to write reports of the operations entrusted to his charge. And, conversely, such reports are very good criteria of their author's capability, or otherwise, to cope with the responsibility conferred on them. A man who carries out work involving interests and expenditures of any importance without making a thorough report, or, as often happens, without making any report at all, to those ultimately responsible is clearly not

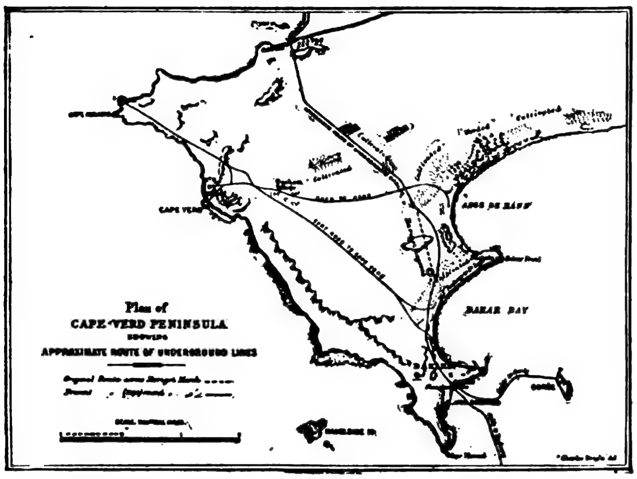

FIG. 1.—MAP SHOWING ROUTE OF YOF-DAKAR CABLES.

up to the level of his calling; while from a detailed report a very satisfactory index is obtained of a man's grasp of his work—apart altogether from the value of the report as a record of the work accomplished and as a guide for the conduct of future operations. And the value of such reports increases as the square of the distance of the scene of operations from headquarters. These few abstract reflections are suggested by the reading of a book of about 100 pages (with various maps and diagrams) entitled: "Reports on Yof Bay-Dakar Cable Repairs and St. Louis Beach Cable Repairs, 1893," by Charles Bright, Assoc. M. Inst. C. E., M. I. E. E.

The report is published, in accordance with that Company's practice of printing the complete logs of its cable expeditions, by the India Rubber, Gutta Percha and Telegraph Works Company, of Silvertown, England, of whose submarine cable engineering staff Mr. Bright is a member.

It will not have escaped the attention of our readers, by the accounts given in THE ELECTRICAL ENGINEER, of the action of the Commercial Cable Company in landing their cable directly on Manhattan Island in order to avoid the uncertainty of land line communication with the former terminus at Coney Island, that submarine cables are often subterranean cables and that the subterranean portions of a submarine cable system are generally more prolific in trouble than the submerged portion of the line. Such seems to have been signally the case with the land lines Mr. Bright was sent to repair, and to the reluctance of those lines to remain in working order for any length of time we are indebted for his interesting narrative of an engineering work of quite unusual nature, carried out under very harassing and discouraging conditions.

Yof Bay and Dakar are two points on the coast of Senegal about 100 miles south of St. Louis, the capital of that French West African colony. From Yof Bay a section of submarine cable parts northward to St. Louis and from Dakar a section parts southward to Bathurst. To complete the line between the two points, the choice lay between a section of heavy cable to be laid well out to sea round a rocky peninsula or a landline across the neck of the peninsula, a distance of about eight statute miles. The latter course was chosen when the submarine cables were originally laid, in 1885, and accordingly two lengths (one spare) of submarine cable were buried in a trench between Yof Bay and Dakar.

Mr. Bright's introduction to these lines came about in February, 1893, when he was detached, at Santa Cruz de Tenerife, from the Silvertown Company's steamship *Dacia*, homeward bound from a repairing expedition in the South Atlantic. Mr. Bright was landed with two cable hands, a jointer, a knot and a half of submarine cable and sundry other stores, and with instructions to proceed to Dakar and repair those land lines. Which he did; and his detailed report of what he found to do and how he did it all forms one of the most interesting records of unconventional electrical engineering experience that we have met with for a long time.

To begin with, even if Mr. Bright's work had had to be done under civilized conditions, instead of in a murderous climate and with a slender amount of skilled help and insufficient equipment, he would have had no easy job on his hands. For those Yof Bay-Dakar cables had a sinister record for a short line of only eight miles. Laid down in 1885, they were repaired in 1886, again in 1889, and again in 1890 or '91 and were once more in a completely demoralized state early in 1893. Indeed, so sinister was the record that much of it had been left unwritten, as those in charge of two of the repairing expeditions had made no note nor report of their work to serve as a guide to Mr. Bright in his operations. Moreover there were no marks along the route of the line, which passed at one point through a marsh the dimensions of which varied accordingly to wet or dry season, the only map of the route being in

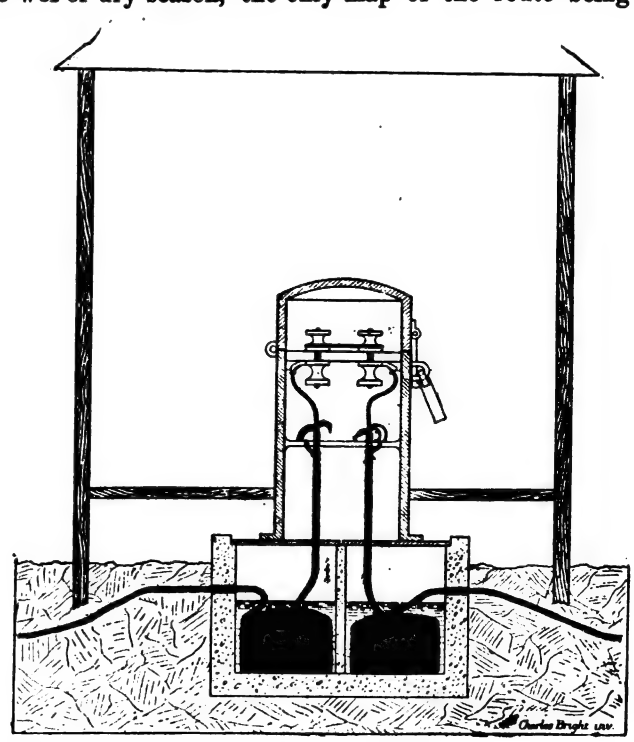

FIG. 2.—BRIGHT'S IRON BOX AND CEMENT TANK FOR CABLE ENDS AT HUT.

the memory of a native guide named Ahmadon, who had served on the previous repairing expeditions. Ahmadon, then, had to serve as compass, sextant, pilot and chart, and he did fairly well, even to freely confessing his ignorance when he really did not know where parts of the line were situated.

Not every young engineer sent to carry out such a very discouraging piece of work would have acquitted himself as well as Mr. Bright did. His preliminary tests showed

both cables to be dead grounded in various places. His subsequent investigations showed that flagrantly bad work had been done before, that the cables were laid at several points in dangerous situations; and the mechanical condition of the cables wherever they were dug up was found to be hopelessly bad. There were no marks of positions, no chart of the route and no accurate record of previous operations. In a few days over a month Mr. Bright relaid a considerable portion of the line, safeguarding the dangerous spots, made a large number of new joints, brought up the insulation of both lines to a working point, 2 megohms per mile, marked out the whole length with iron posts, placed 250 yards apart, marked every joint with stone pillars, prepared an accurate chart of the route of the lines and executed sundry minor repairs to the huts at the two ends of the line, besides executing, by way of diversion, some tests and repairs on the sea sections at St. Louis, a hundred miles distant from the scene of his main operations.

Mr. Bright narrates in great detail the entire course of his work and gives some interesting particulars as to the behavior of gutta percha and insulated cores under tropical conditions, besides adding numerous suggestions aimed to secure a greater measure of durability for future underground telegraph lines. Of the report itself, as a report, it is not necessary to speak further except to say that it reveals considerable organizing ability on the part of its author by the particulars Mr. Bright gives of his superintendence of the work, of his measures to preserve the health of his staff and to maintain good relations with the native authorities and with others who might in any way have influence over the fate of the cables; the report as a whole provides Mr. Bright's employers with a complete and accurate survey of the line and of the condition of the cables.

It appears that part of each line consists of gutta percha and part of india rubber core. Both seemed to have fallen into similar conditions of decay. The india-rubber cable was laid across the marsh already referred to; of its condition Mr. Bright speaks as follows: "Wherever the cable was picked up and opened out here (in the works) the india-rubber was found to be in a perfectly pulpy state, not unlike putty, size, or the original condition of the india-rubber gum when first collected." It seems that the india-rubber cable was put down in the marshy ground on previous repairs because such cable is believed to stand alternations of temperature and humidity better than gutta-percha; Mr. Bright suggests that the failure of the core to act up to its reputation in this case was due to imperfect vulcanization. As a matter of fact, however, no rubber core could be expected to long maintain its insulation under the conditions of alternate moisture and dryness and high temperature without better outer protection than is afforded by the serving and armoring of a submarine cable.

The following is the account given of the condition in which the gutta-percha core was found at the joints and at kinks where the cable was picked up: "At almost every part of the line that I had occasion to disturb I found both the cables subject to a succession of kinks, causing the sheathing wires to 'bird-cage,' and in many instances leaving the core entirely exposed, the gutta-percha in consequence gradually crumbling away in a white, chalky state, the conductor usually being left bare in places and in some instances making contact with the sheathing wires." In the 32 joints that Mr. Bright cut out he found the gutta-percha invariably in a completely decayed condition, leaving the conductor bare in places. The joint itself as a rule was in fair condition but the core on either side was always in a completely perished state, the gutta-percha gradually dropping off in a white, chalky form, after having rotted away to "needle-points." Speaking again of the deterioration of the gutta-percha Mr. Bright says: "The condition of the gutta-percha in the lines was found to be principally of the dry, cracked, chalky description already alluded to, but in places it was also found to be in a 'tacky' state, not unlike treacle, and it was soon found to be impossible to make anything like a respectable joint with gutta-percha in this state."

That with cables in this state and all the added difficulties of marshes, travelling sand hills, gullies, and other obstacles, tropical heat and tropical labor and the disadvantage of an insufficient stock of new material Mr. Bright succeeded in effecting creditable repairs and in leaving the lines in working condition speaks well for his skill and perseverance. We trust for his own sake that when the Yof Bay-Dakar line next needs attention he may be otherwise occupied in less arduous and trying work.

At the end of his report Mr. Bright summarizes a number of points which naturally occurred as a result of his experience. He would eschew joint boxes in buried cables in favor of regular splices; and he condemns spare coils of cable at joints as sources of trouble. He also protests against the use for land lines of strained cable that has been recovered in deep sea repairs. He thinks india-rubber core on the whole more suitable for land line work than gutta percha. Among a number of suggestions bearing on general details of the work the one of most practical bearing as a principle is that advocating the use of a cable with air-tight casing instead of cable of the ordinary submarine type. On this point Mr. Bright is a little over cautious where he hazards "even a hermetically sealed lead-covered cable," for this is undoubtedly the thing that should be used, and no better proof is needed than Mr. Bright's description of the condition of the gutta percha and india-rubber cables on the Cape Verd peninsula after a much interrupted life of less than eight years. To bury anywhere except deep down in permanently damp and cool ground a non-leaded cable is simply to invite deterioration of the core and expensive interruptions and repairs. Lead-covered cables with an outer protection of flat iron wires or strip properly buried would be practically indestructible and everlasting in spite of alternating temperature, dry sand or wet marshes.

The cement storage tank and iron box which Mr. Bright proposes for making fast and protecting the cable ends at a cable hut is undoubtedly a good idea and shows his predilection for a thoroughly workmanlike job; the expense and inconvenience of such construction at the situations in which cable huts are generally established will probably militate against its adoption.

H. L. W.

ALUMINUM-COPPER TELEGRAPH WIRES.

Tests have recently been made of some aluminum-copper wires intended for use in connection with the Monteil Trans-African Expedition. The percentage of the alloy composing these wires is 40 per cent. aluminum and 60 per cent. copper. The resistance of a kilometre of these wires having 1mm. cross-section is found to be 31·1 ohms for soft and 33·29 ohms for hard-drawn wire, the resistance of an ordinary copper wire of the same dimensions being 16·45 ohms. The tensile strength of wires of this alloy, 2·3mm. in diameter, was found to be, on an average, 28 kilogrammes per square millimetre (17·78 tons per square inch).

GOVERNMENT TELEGRAPHY IN TURKEY.

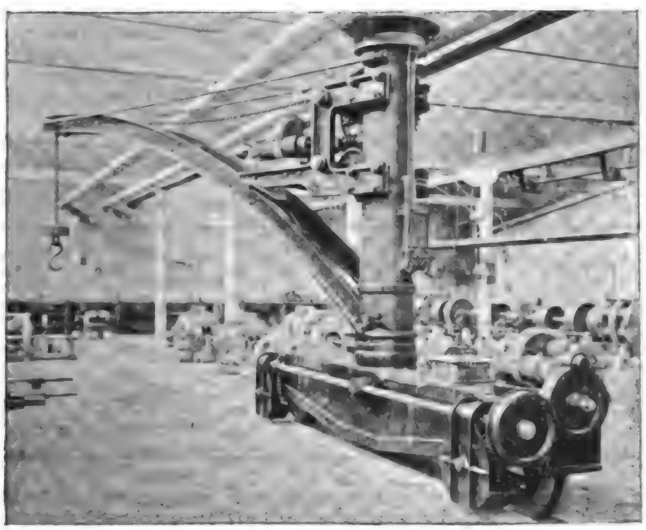
The London correspondent of the *New York Sun* writes: "I have seen to-day an amusing official note from the censor at Constantinople. It is addressed to a well-known correspondent and says that in order to make a message more accurate and explicit he added ten words to the latter's telegram the previous night, and asks the correspondent to send along $2 to pay for the added words. It is useless to protest in Turkey, so the correspondent sent the money, but at the same time respectfully suggested that if the censor would write his message entirely and merely forward him the weekly cable bill it would save him much unnecessary trouble. The censor is taking time to consider whether this offer is serious or sarcastic."

HENRION ELECTRIC JIB CRANE.

THE accompanying illustration represents a crane installed in the works of M. Fabius Henrion, the well-known electrical manufacturer, at Nancy, France. The crane traverses one of the shops having a length of 260 feet, and has a reach of 16½ feet, and is, therefore, able to cover an area of 260 by 32½ feet. The crane has a capacity of six tons, and takes the castings as they arrive and swings them successively into the various machine tools, from there to the assembling, then successively to the testing, painting and packing departments.

The crane is guided below by a single Brunel rail, and above by two H beams, below which are fixed two conductors, from which current is taken by friction contacts.

The motor placed on the carriage effects the traversing



HENRION SINGLE RAIL ELECTRIC JIB CRANE.

of the crane. This movement is controlled by the regulator beside the dynamo; it only requires the turn of a handle to the right or left to go forward or backward and slower or faster. The reversing of the crane movement is obtained by the reversal of the current in the field magnets. The brushes of the dynamo are of carbon and remain absolutely fixed under all conditions of working. The motor is placed on a bracket attached to the vertical column and jib and operates the raising and lowering movements, and is controlled by a regulator fixed to the column. When the load descends the motor is converted into a dynamo and acts as a brake.

LITERATURE.

Extracts from the Private Letters of the late Sir William Fothergill Cooke, 1836–39, Relating to the Invention and Development of the Electric Telegraph; Also a Memoir by Latimer Clark, Esq., F. R. S., Past President Inst. E. E. Edited by F. H. Webb, Sec'y Inst. E. E. London and New York. E. & F. N. Spon, 1895.

ORIGINAL contemporaneous correspondence, written with an immediate and without an ulterior purpose in view, constitutes, when accurately reproduced and impartially edited, the very best of historical material. We are therefore grateful to Mr. Webb for giving us in this tasteful little volume, a reprint of a considerable number of letters written by William Fothergill Cooke, mostly to his mother and other family friends and relatives. The series commences at the time when, a medical student at Heidelberg, he first conceived the idea of a practical electric telegraph, which in his first letter to his mother dated April 5, 1836, he says was "some weeks since," down to a date subsequent to the successful establishment of the first operative telegraph line between Paddington and Drayton, late in 1839. The hopes and fears of the young and enthusiastic inventor during these fateful three years are vividly portrayed, and incidentally, many items of interest relating to the early history of the telegraph in Great Britain may be gleaned from these letters. June 8, 1838, Cooke writes to his mother:—"I have just tried a fresh series of experiments to the extent of nearly 40 miles, and with more satisfactory results than before. Therefore to anticipate a failure would be absurd." On this letter is the following endorsement in the handwriting of his mother:—"God be with my blessed boy, and prosper this mighty discovery"; a sentence worthy to take its place in the annals of the telegraph beside the historic despatch with which Morse, in 1844, opened his Washington-Baltimore line—"What hath God wrought?"

The appended memoir of Cooke by Latimer Clark is reprinted from the proceedings of the Institution, in which it was published in 1879. It could have been wished, in the interest of the truth of history, that the editor might have seen fit to correct by annotation, or otherwise, certain statements of Mr. Clark which betray far more regard for national prejudice, than desire to ascertain and state the truth in reference to certain controverted facts. Thus on page 91, after referring to notices of various European experiments in telegraphy which had been published and circulated during the year 1837, and also to Morse's letters to the *Journal of Commerce* of September 4, and to the Secretary of the Treasury on September 27, 1837, Mr. Clark says: "From these letters it is sufficiently evident that the American Telegraph grew out of the efforts of Messrs. Cooke & Wheatstone and other European telegraphers, and that there is no ground for that claim of priority which it has sometimes been endeavored to set up." He also intimates, on the authority of Dr. Hamel, that the reason why Cooke and Wheatstone could obtain no patent in this country was "because the chief of the Patent Office was a friend of Professor Morse." The inexcusable malignity of this utterly false insinuation will appear from the simple statement that Cooke and Wheatstone not only *did* obtain a patent in this country, and this so far as appears, without the slightest opposition from Professor Morse or anyone else, but their patent was granted, as the published records of the Patent Office show, before that of Morse.

There is abundance of unimpeachable evidence, with which Mr. Cooke's biographer could not but have been familiar, that the apparatus which Morse exhibited in New York in successful operation on the 2d and 4th of September, 1837, had been in all its principles and essential details, devised on board the Sully in 1832. The *invention* must have been made at some time before it was possible to give it a mechanical embodiment, and the date of that invention, so far as Morse's original apparatus was concerned, was 1832, as testified to by the captain of the vessel and confirmed by a large number of his fellow-passengers, in the telegraph suits fifteen years later. It is true that Cooke and Wheatstone had a commercially working line in operation before the end of the year 1838, while Morse did not accomplish the same thing until six years later, but that is surely insufficient ground for the positive assertion of Mr. Clark that the invention of the latter "grew out of the efforts of Messrs. Cooke and Wheatstone." The Secretary of an institution like that of the Electrical Engineers, owes it to himself not to let such unwarrantable insinuations and mis-statements pass under his editorial supervision unnoticed and unchallenged.

F. L. P.

Municipal Ownership: Its Fallacy. By M. J. Francisco. Fourth Edition. Paper cover. 100 pages. Pub. by the author. Rutland, Vt.

Addressing himself once again with undiminished zest to the fight against the municipal ownership of electric lighting plants, Mr. Francisco has brought out another edition of his pithy and effective pamphlet, revised up to date. The merely argumentative part of the test is now supplemented by a number of legal and editorial opinions on the subject, as well as by useful tables showing the real cost of lights as furnished by private companies and municipal plants.

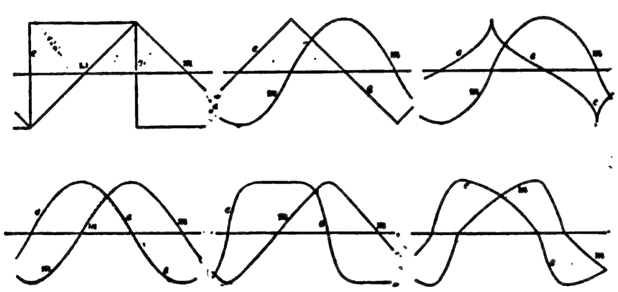
Such literature cannot have too wide a circulation. The tendency to divert public funds raised by taxation into the channels of specific commercial enterprises is strongly pronounced, and it is based upon the fallacious supposition that by means of such expenditures, cities can add to their income and also lighten the general burden of taxation. The theory is pretty but it rarely works out well. Mr. Francisco, who has made a close study of all points of the subject, holds that no municipal plant can pay; at least we believe that to be his bottom conviction on the subject. It might be admitted that one or two plants of this nature are profitable, and the argument against them remains as strong as ever, for some of the instances to the contrary present failures that are simply stupendous. Indeed, it is one of the saddest spectacles of modern times to see how the load of public indebtedness is growing in the various civilized countries, and quite as much from state and municipal enterprises as from preparation for war. If the standard of performance improved with the increase of debt, there might be some consolation, but the various recent investigations in different cities reveal waste, extravagance, mismanagement and dishonesty that are positively appalling.

ALTERNATING CURRENT CURVES.[1]

BY CHARLES E. EMERY, PH. D.

The paper refers preliminarily to the facilities for general investigation available when the variations in magnetism, electromotive force and current, in alternating current apparatus, are assumed to be accurately represented by sine curves. It states that the methods are strictly applicable for such curves only, though very valuable practical results have been obtained for other curves by special methods involving "equivalent sine curves" and a modified or "equivalent angle of lag." The paper urges that it is therefore desirable to develop a general system for formulating and integrating the value of the "instantaneous watts," applicable to curves of different shapes, which will include an approximate sine curve as a special case. Such a system should avoid the necessity of using equivalent values and enable the distortions of alternating current curves to be explained directly by formulating the conditions which produce the same instead of considering arbitrary "harmonics."

In order to accomplish this it is first necessary to develop a general formula which will approximately represent curves developed in practice. The E. M. F. is at first assumed as proportioned to a function represented by the variable base x raised to a power which is constant for each particular case developed. The integral of this equation referred to the same origin gives values proportioned to the corresponding momentary magnetic flux. Curves based directly on the primary function are illustrated to show its remarkable features, though stated to be not as well applicable to represent alternating current curves as the equations of the second series in which the primary function is subtracted from a constant bringing the origin at zero of magnetization The differential and integral equations thus developed are divided through by the maximum ordinate and multiplied by s, representing the base for one-fourth period, to bring all values in terms of



FIGS. 1, 2, 3, 4, 5 AND 6.

a uniform base, when the resulting equations of Series II. take the following form :

$$e = s - \frac{x^u}{s^{u-1}} \tag{11}$$

$$m = \frac{u+1}{u\,s^u}\left(s^u\,x - \frac{x^{u+1}}{u+1}\right) \tag{12}$$

in which u is a partial exponent constant for each particular curve developed.

If $u = 1$, as shown in Fig. 2, the curve of E. M. F. or e becomes a triangle and the curve of magnetization m a parabola, showing that the values for partial exponent, u = unity, are for both series of equations identical.

As shown in Fig. 3 for which $u = 0.5$ for values of u between unity and zero the curve e takes a cusp form and the curve m a rounded form. If $u = 2$ both curves e and m, as shown in Fig. 4, approach the sine form represented in dotted lines, the curve e being a parabola slightly greater in area than a sine curve and the curve m consequently of slightly less area than a sine curve.

By using a fractional exponent both curves can be brought still closer to the sine form. For $u = 1.781$ in Eq. (11) the square root of the mean square of the ordinates of the resulting curve e is 7.071 or the same as for the sine curve. The two curves being derived from different functions cannot absolutely coincide, but the differences are so slight that to find them the values must be extended to several decimal places, and, in plotting, the curves seem identical. If the value of u be still more increased the curve of magnetization m rapidly approximates the shape of a triangle and the curve e of E. M. F. approximates a rectangle, so that doubtless for u = infinity, the curve would take the form shown in Fig. 1.

The change above indicated is so rapid that for $u = 6$, as shown in Fig. 5, the curve e has already taken the general shape of a rectangle with well rounded corners, and the curve m the general shape of a triangle with rounded point. The curve e resembles closely the curve of electromotive force given by a dynamo from which armature reaction has been eliminated, as shown in a recent paper,[2] and the corners may be made still sharper by increasing the value of u.

Unsymmetrical curves based also on $u = 2$ in Eqs. (11) and (12) are shown in Fig. 6. These curves are plotted with the same values of the ordinates as in Fig. 4, but the portion of the curve showing decreasing magnetism and increasing E. M. F. is plotted in a distance less than a quarter period, and the remainder of the curve in a distance greater than a quarter period, so that the sum of the bases equals one-half period. These curves show that the phase relation of curves m and e may be changed simply by the shape of the curve m of magnetization. The plus and minus branches of this curve must be similar and of equal area, but the change of magnetism and of electromotive force during the increase of the latter need not be at the same rate as during the decrease.

It will be observed that this very large variety of curves are finally derived from two simple algebraic equations for each series, those for Series II. being given in Eqs. (11) and (12). The first equation of each series is the differential equation of the second equation of that series, but the integration required to pass from the first to the second is already performed, the equations are complete and may be utilized at once by simply substituting numerical values.

The distinguishing features of the different curves are shown in the following table :—

DISTINGUISHING FEATURES OF THE DIFFERENT CURVES.

General Shape of Curves of E. M. F. and Current.			$\sqrt{\text{mean}^2}$ in scale of 10	Relative Ratio Max. to Effective Voltage.
Triangle........................	$u = 1$	Fig. 2	5.774	1.732
Sine Curve..........................	—	—	7.071	1.414
Approximate Sine Curve.......	$u = 1.781$	—	7.071	1.414
Parabolic Curve	$u = 2$	Fig. 4	7.303	1.369
Approximate Rectangle.........	$u = 6$	" 5	8.895	1.124
Rectangle..........................	$u = \infty$	" 1	10.000	1.000

The paper then shows curves of E. M. F. and current differing in phase, and develops methods for obtaining the ordinates of these curves from the same origin for any desired angle of lag. The equations of the momentary values of E. M. F. and current are then multiplied together and integrated, giving diagram watts which are stated for various differences of phase.

The paper points out that by this method it is possible to use a different function for descending and ascending branches of the curves, thus producing unsymmetrical curves, and yet perform the integration and that this function may be developed by imposing upon the original function another function based on the actual conditions which produce a certain change so that the curves finally resulting will include all the conditions. The paper states that it has been pointed out that the observed distortions of alternating current curves may be illustrated by imposing upon the primary function a series of harmonics, but to make such a method strictly rational it must be shown that each condition, if formulated, will produce the equations of such a harmonic, and continues that it is not probable that such is the case, but that the method proposed gives facilities for considering the general conditions whatever the shape of the curves that will represent them.

In the discussion of the paper by Prof. Pupin and Mr. Steinmetz both deprecated the tendency of mechanical engineers to use empirical formulæ and claimed that such formulæ were unnecessary, as rational formulæ were already available, since by the application of different harmonics curves of various shapes could be produced. Dr. Emery, in response, claimed that the curves he had developed were no more empirical than the sine curve, since the actual curves were rarely exact sine curves. Moreover the actual shape could be represented by his system without resorting to harmonics, and the modification due to conditions could be impressed upon equations in the form he stated them, by multiplying such equations by other equations representing such conditions. He believed that the method of investigation by means of actual momentary values would meet with increasing favor and considered the equations given as, in effect, tools to assist in the prosecution of a higher order of investigation.

DETROIT, MICH.—The Wolverine Electric Co. has been organized, with a capital of $10,000 for the manufacture of specialties and supplies and construction work. Its officers are G. A. Brooks, president, C. F. Scott, secretary and treasurer, and Hiram Marks, general manager. It has a 150 light machine.

1 Abstract of a paper read before the American Institute of Electrical Engineers, Niagara Falls, N. Y., June 27, 1895.

ELECTRICAL WORK AT THE ATLANTA EXPOSITION.

The Atlanta Exposition, which is to be opened to the public on September 18, is rapidly assuming definite shape, and commissioners are arriving in the city from all parts of the country to inaugurate the commencement of the buildings of the respective States with appropriate ceremonies. The electrical field will be well represented in Electricity Building in the exhibits. The General Electric Company intend to make a most elaborate show. Their space is to occupy at least 1,000 square feet, and possibly half as much more. The design of their exhibit is understood to be original and striking, and likely to create a sensation. They are entering into the work with zeal and liberality, evidently determined to maintain their well known standard. The Westinghouse Electric and Manufacturing Company have also secured one of the large central spaces, which will be filled with an extensive and interesting exhibit. The old rivalry for excellence and novelty of design between the two companies, which now becomes a prominent factor in every exhibition, will be in full force. Another important exhibit will be that of the Brush Electric Company, which has taken a large amount of space and is to be fitly represented. The Fort Wayne Co. will also be in the front rank. An exhibit second to none in general interest will be that of the American Bell Company, which is now actively engaged in the work of preparation in co-operation with the Southern Bell Co. and the Atlanta Exchange. Its display, which will cover over 1,000 feet, will comprise a complete central station, operating telephones in all parts of the grounds, connected with the main system in Atlanta, and with the long distance system throughout the State. Its space is to be handsomely and expensively fitted up, and the growth and progress of the telephone business is to be thoroughly illustrated.

In view of the remarkable impetus recently apparent in the business of the South, this exposition gives an excellent opportunity for the advertising of Northern wares, and that electricians are fully alive to its importance is shown by the fact that many Northern electrical firms have applied for space, and are expending much care and money in preparing their exhibits. Unquestionably one of the most attractive features of the exposition will be the electric fountain in the centre of the great lake. Of course, this has been designed by and will be erected under the supervision of Mr. Luther Stieringer, whose name is now identified with the most successful production of spectacular effects by the play of light on moving water both in this country and in Europe. Mr. Stieringer who was the Consulting Electrical Engineer of the World's Fair, holds a similar commission at the Atlanta Exposition, and the management is understood to have expressed the highest commendation of the results of his designs. Although recent expositions have been indebted for much of their popularity to the beauty of their electric fountains, the coming display promises to far surpass in brilliance and originality anything of the kind yet seen. The water designs are rich in character and bewildering in variety. They consist of wheat sheaves, ring curtains, rings of geysers, oscillators, lily jets, large and small parabolas, a mist bank, and a mammoth geyser. The mist bank is an entirely new idea in hydraulic effects. It will envelop the fountain area in a dense mist of spray, and will be illumined with colored lights in endless combinations. Twenty-three powerful electric projectors will be used, each of which will be not less than 250,000 candle-power. To attain the countless hydraulic effects of which the fountain is capable a perfect network of pipes will be needed. The water will be furnished to the fountain at 100 pounds pressure through a sixteen inch main having a capacity of 15,000 gallons a minute, by the pumps of the Worthington Pump Company, of New York, whose comprehensive exhibit in the machinery hall will be one of the most interesting displays of the exposition. Rising from the surface of the lake, the fountain structure containing the operating chamber will present the appearance of a half-submerged rocky island of irregular form, some 100 feet long and 50 feet wide. It is to possess a distinctive feature never presented at any of the great expositions. When in position, the fountain will be plainly visible from base to apex from almost every point on the exposition grounds, and the mirror effect produced by the reflection of the play and flash of color and light upon the waters of the lake will be unique. The highest jets will rise over one hundred feet from the basin of the lake and will be tipped with light.

The Western Electric Co. is reported to have some original plans for its exhibit. This will be readily believed by those who saw its wonderfully clever and successful exhibit at the World's Fair. An Electric Scenic Theatre is promised by one of the exhibitors whose name is not yet disclosed.

ELECTRICITY BUILDING AT THE ATLANTA EXPOSITION.

VETO OF ELECTRIC LIGHTING LEGISLATION IN PENNSYLVANIA.

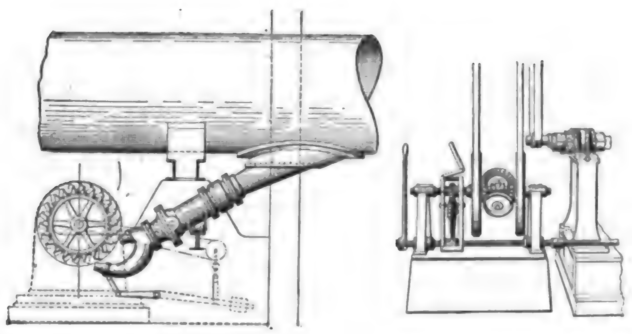
Gov. Hastings of Pennsylvania has vetoed the twin electric light bills, which provide that, in addition to boroughs, all cities of the first, second, and third classes shall have the right to manufacture electricity for municipal, borough, or commercial purposes. The veto was in accord with strong petitions which have been sent to the Governor from all parts of the state, and the ground for the veto is that the bills require boroughs and cities to condemn existing electric-light plants and pay for them as conditions precedent to furnishing light on the part of the municipality for its own use and the use of its inhabitants. "No matter how antiquated, useless, or undesirable the works of such corporation may be to the municipality, it is required by this bill to make the purchase before it can exercise the power to light its own streets and furnish light to its citizens." Gov. Hastings says: "I am of opinion that the furnishing of light, at least for municipal purposes, is a proper function of the municipality as such, and that it should in no wise be abridged by legislation."

LONG DISTANCE TRANSMISSION AT 10,000 VOLTS.

(The Pomona Plant.)[1]—I.

BY GEORGE HERBERT WINSLOW.

The Pomona plant was installed in the summer and fall of 1892 for the San Antonio Light and Power Company, of Pomona, Cal. It was increased in the following spring, and early last year the capacity of the plant was doubled by duplicating the entire equipment. At the present time, when the plant has been in regular operation for more than two years, and its complete success has established confidence in the successful outcome of many similar projects of greater magnitude, it seems fitting to present a careful description of the entire installation. The electric plant was installed under the personal direction of the writer,



Figs. 1 and 2.

as electrical engineer, who presents many of his personal observations on its construction and operation.

The plant is used to transmit energy from a waterfall to substations at Pomona, 13¾ miles distant, and San Bernardino, 28¾ miles distant, from which points it is distributed for incandescent and arc lighting. It consists of a Pelton water power plant and a Westinghouse alternating current transmission plant in which generators supply currents to sets of raising and lowering transformers operating at 10,000 volts, and delivering current to the local circuits at 1,000 volts.

The water power for this plant is derived from the San Antonio creek, which is chiefly supplied by the melting snows and the rains on San Antonio Mountain. Side cañons, however, also furnish some water.

At the lower end of the valley a sharp ridge extends eastward from the side of a neighboring mountain, from which it originally split off, and blocks up the valley except at a narrow place at which bed-rock is exposed and through which the stream plunges suddenly downward at least 90 feet between precipitous walls of rock, forming the San Antonio Falls. To utilize this fall, part of the water is diverted by a dam about 200 feet above the falls into a canal which conducts the water to a tunnel passing through the ridge. At the other end of this tunnel the water enters a large pipe leading to the power-house, which is located 412 feet below the level of the outlet of the tunnel.

The pipe is of sheet steel, double-riveted throughout, and was delivered on the ground in sections having a length of 11 feet 6 inches. These sections consist of four sheets each three feet long. The diameter of the pipe up to within 450 feet of the power-house is 30", with the exception of the length which connects it to the sand-box at the top of the pipe, which length is considerably expanded, so as to allow the water to flow slower on entering, and thus to reduce the entrainment of air. Near the power-house a "reducer" is inserted in the pipe to reduce the diameter to 24", and this size is maintained from this point to the power-house. The pipe was designed to carry 2,000 miner's inches of water (measured under a head of 6 inches), without unnecessary loss by friction. The capacity is equivalent to 50 cubic feet per second, or 1,882 H. P. at 390 feet effective head, assuming a wheel-efficiency of 85 per cent. This is nearly three times the power for which the present station was built, but the extra capacity of 1,000 horse-power obtained by increasing the capacity of the pipe costs so little when compared with the cost of building an entire new pipe-line, that it is much more profitable to lay the larger pipe in the first place, if sufficient water can ultimately be developed to utilize the added capacity.

The thickness of the pipe is increased as it nears the power-house to provide for the increase in pressure in the lower parts. At the first bend it is made greater than that of the sections above it on either side, because the pressure on it is greater. After passing the second air-valve, first No. 10 and then No. 8 steel is used, the latter size being continued to within a short distance of the power-house. The last few lengths are of No. 6 steel.

The horizontal distance between the mouth of the tunnel and the power-house is 1940 feet, and the difference in level between the tunnel and the floor of the power-house is 412 feet. The total length of the pipe, following the line, is 2,370 feet.

The sections of pipe as received from the makers were coated with asphalt both inside and out, and parts of this coat were of course scraped off through rough handling. After the pipe was laid and jointed, a man went through it and painted the joints with hot asphalt to prevent rusting.

In order to protect the pipe from the great changes in temperature which occur in the mountains between midday and midnight, earth and loose rock were placed around and on top of the pipe without any tamping, and where enough earth could not be conveniently obtained, brush was cut and piled on the pipe and covered with a light layer of earth and rock.

The lower end of the pipe is closed by means of a 24 in. Ludlow gate-valve, which is bolted to a cast-iron flange riveted to the end of the pipe.

The stem of the valve is geared to a small hand-wheel, partly on account of its weight, but chiefly in order that the gate may not be shut too quickly, as otherwise the pipe would be subjected to severe strains, resulting from suddenly checking the velocity of the column of water. The gate is connected by a tapering pipe of steel to a horizontal, cylindrical steel receiver 20 feet long and 42" inside diameter, from which the water is distributed to the wheels.

Two tapering cast-iron pipes (a large and small one) are bolted to the lower side of the receiver at an angle of 30 degrees. These pipes conduct the water from the receiver to the under sides of two independent Pelton water wheels, which drive an alternating current generator and its exciter. (See Fig. 1.)

The pipe running to the generator wheel is provided below its valve with two nozzles cast in one piece and attached to the valve by means of a limited ball-and-socket joint, which permits them to be moved vertically to deflect the water.

A set of tips of different diameters is supplied with each nozzle, so that the size of the jet used may correspond to the maximum load and thus unnecessary waste of water be avoided. The tips for the generator-wheel range from 1½ to 2½ inches in diameter, while those for the exciter are from $\frac{7}{16}$ to ¾ inch. When tips are used of the proper size for the full load there is no need of throttling at the full load, and, therefore, no loss from this cause; and with the deflecting nozzle there is no waste of water at full load, so that for full load the two arrangements are equally good. This is not, however, the normal condition of operation of a lighting plant, for in such a plant each dynamo is driven by a separate wheel, and the load is constantly changing, so that here the deflecting nozzle has the advantage. The deflecting nozzle is also to be preferred under high heads, to avoid the risk of straining the pipe by suddenly checking the flow of water, as would be necessary with a throttle valve if the entire load were suddenly thrown off.

The speed of the generating-wheel is maintained constant for different loads by deflecting the stream. This is done by raising or lowering the deflecting nozzle from the dynamo-room by means of a lever fixed to a shaft which passes through the wall and carries a short lever connected to the nozzle by a link. The weight of the nozzles is counter-balanced by a movable weight on a horizontal lever-arm fixed to the shaft. The change of position of the nozzle is made automatically by the use of the Pelton differential governor. The arrangement for governing is briefly as follows: The generator is geared to stop itself by turning the water off the wheel, and

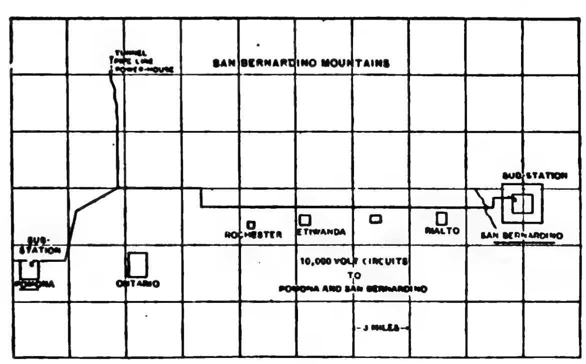


Fig. 3.

the source of constant speed is geared to speed up the generator by a contrary action. These two actions neutralize each other when the generator-speed is the same as the fixed speed, but when either preponderates the difference acts. Thus an increase in generator speed will act to stop the generator, while a decrease, by making the fixed speed predominant, acts to speed up the generator. The governor consists, in part, of two similar miter-wheels which are mounted upon pulleys and placed face to face, loosely, upon a horizontal shaft, and are driven at equal speeds in opposite directions, one by the generator shaft, and the other by the exciter shaft. The speed of the pulleys is 200 R. P. M. In Fig. 2 it will

1. Abstract of a paper read before the Amer. Inst. of Elec. Engrs., Niagara Falls, June 26-30, 1895.

be seen that between these wheels, and at right angles to the supporting shaft, there is fixed to the latter a cross-bar, carrying two miter-wheels, one at each end, which mesh with the two oppositely revolving miter-wheels first mentioned. The result is, as long as the two outside wheels are revolving at the same speed the two central wheels will merely revolve upon their axis without tending to move in either direction the arms upon which they rotate. Now, if the generator-speed increases, the corresponding side of each central wheel will have to travel faster forward than the other side travels backward, and the difference between these two movements will result in a movement of the central wheels in the direction of a faster wheel, and the cross-bar will consequently move the same way. The shaft to which the cross-bar is attached will, of course, turn with it, and as this carries a pinion meshing in a toothed quadrant connected to the lever which controls the nozzles, the stream will be pulled away from the wheel until the generator speed falls to its normal value.

In order to avoid see-sawing it is the practice in this plant to reduce the head every morning during the light load. This is readily done by opening the extra 4" relief-valve and allowing water to escape until the pressure has gone down to that corresponding to the desired head. The valve is then set tentatively until the pressure remains about constant, when the final adjustment is made by partly closing the valve on the generator-wheel pipe. Meanwhile the governor throws more and more of the stream onto the wheel to compensate for the decrease in head, and the see-sawing stops.

To start the plant, the governor ratchets are first disengaged and the exciter is brought to a moderate speed; the generator is then started and its field is charged; it is then brought to about three-fourths of its full speed, and the speed of the exciter is then slowly increased until the cross-bar on the governor ceases to move. At this moment the ratchets are thrown in, and the governor takes charge of the generator speed. The speed of the exciter is now slowly increased to its full value, which of course brings the generator to full speed. The speed of the exciter-wheel is regulated by a small throttle-valve, the changes in the position of which do not have any noticeable effect on the pressure in the pipe, owing to the small size of the jet controlled.

The power house is 66 ft. long by 30 ft. wide, and has walls 12½ ft. high. The walls, which are of concrete, were all built by tamping concrete in a space between temporary wooden walls forming a mould, a few feet of wall being built at a time, and the planks then loosened and raised to the height of the next section, the walls being thus made at the least expense for timber.

The station was built to accommodate four 120 K. W. 7,200 alternation, 12-pole, single-phase Westinghouse alternators, with

GENERATING STATION, SAN ANTONIO LIGHT AND POWER CO.

their full complements of raising-transformers and switchboard apparatus, and two exciters. The first installation consisted of one generator with one 90 ampere 125 volt "I" exciter, capable of exciting the four alternators, and of 126 K. W. capacity of oil transformers in 21 units of 6 K. W., one of those units being kept as a reserve.

Several different methods of connecting the raising and lowering transformers were given careful consideration, the test of actual use favoring a series connection for both primary and secondary coils of both sets of transformers, a plan which has proved to be thoroughly reliable in its practical operation at the Westinghouse plant at Portland, Oregon. It was however decided, in order to be able to change the initial pressure on the line in case of accident to any of the converters, to connect the primary coils of the raising transformers in multiple to the dynamo, put the line coils all in series with the line and with a similar set of coils in the lowering transformers, and connect the other coils of the latter in multiple to the distributing circuits.

The next question was what size of transformers should be used. Many small transformers meant less cost per unit for repairs, greater facility of handling, and greater flexibility in case it were desired to change the voltage on the line. Their use, however, also meant greater first cost, more complication, and somewhat lower efficiency, but these points were outweighed by the former, and a transformer unit of 6 K. W. was chosen. Each transformer is contained in a cast-iron box provided with vertical outside ribs, which serve to stiffen it, and also to cool the

POLE LINE THROUGH SAN ANTONIO CANYON, POMONA POWER TRANSMISSION.

oil with which the box is filled, and which entirely covers the transformer. The box is covered by a cast-iron lid, which has conducting and radiating ribs both outside and in, the inner ones dipping into the oil at its hottest part and helping to cool it.

It also has an oil-gauge to show whether the tops of the coils are completely covered without having to raise the lid. The boxes are supported upon a substantial timber frame, upon the top of which two iron bands serve incidentally to protect the wood, but chiefly to metallically connect the boxes to each other and to the earth, in order to dissipate the static charge received by the boxes, which is very unpleasant. The core of the transformer is connected to the box by a copper strip fastened around a block of wood upon which the core rests in the box, and to provide against the danger which would result from accidental connection between the primary and secondary coils, an insulated sheet of copper is placed between the latter and close to the dynamo-coil, and is connected to the core by a tongue which is stuck between the plates.

The line-coil of No. 7 B. & S. gauge wire, is inside the dynamo coil, and is kept everywhere at a distance of one-half inch from the latter, the ground plate, and the core, by walnut blocks boiled in paraffin, between which ample openings are left for circulation of the oil. The ratio of transformation is 1000 to 450, so that in a bank of twenty transformers the dynamo pressure required for 10,000 volts on open circuit is 1,110 volts, and on full load about 3 per cent. more than this, or 1140 volts. The space between the 1,000 volt coil, and the core, is one-eighth of an inch. The terminals of the line-coils are brought up through the oil in mica-fibre tubes passing through heavy glass bushings held in paraffined wooden blocks which are attached to the sides of the boxes. The 1,000 volt terminals are similarly supported, but without glass bushings. The transformers are all connected in multiple to the dynamo-circuit, which is supported directly above them on a light pine framework, which also supports the fuse-blocks. The latter are single-pole, and the fuse passes through a hole in a marble block, the object of so confining the arc being to blow it out by its own force. Only one fuse is used on each transformer. The secondary or line coils are all connected in series by U-shaped insulated wire connections which may be readily detached when making periodical tests for insulation of terminals, and which are entirely independent of the frame-work supporting the dynamo circuit. Accidental contact with the exposed connectors is prevented by the framework above mentioned, and there is an inflexible rule that the high tension side of the transformers shall not be touched under any circumstances whatever, while the dynamo is running.

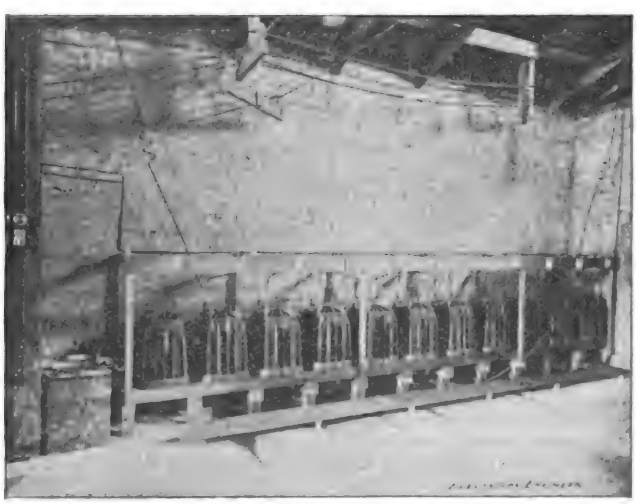
Clark's insulation is used on all wires connected to the trans-

formers and to the dynamo, and the terminal wires of the full bank, which must often be disconnected for testing, are further insulated by heavy glass tubes at points where they might come in contact with other wires. All other transformer wires are supported upon double petticoat glass insulators, and all dynamo-wires upon porcelain knobs.

The switchboard is of narrow red-wood boards, tongued, grooved and beaded, nailed on a framework of yellow pine, the latter supported on porcelain insulators to keep it dry. The switchboard outfit for the one generator and one exciter consists of two 120 amp. fuse blocks, field rheostat with a 25 amp. D. P. field switch with fuses, one 150 amp. ammeter and a 200 amp. D.

OUTLET OF TUNNEL, PIPE LINE IN CENTRE OF PICTURE.

P. jaw-switch. From this switch the current passes to two 4-dynamo, marble switch-panels which are connected in multiple to the dynamo, and are each provided with two pairs of contact plugs. By means of these panels and of the two 200 amp. dynamo-changing switches below them, any feeder can be operated from any dynamo which is connected to the switch-panels. Between each panel and its switch is a pair of 65 ampere Wurts shunt-wire fuse-blocks, each provided with an extra fuse and shunt which can be connected by inserting a plug should it be desired to double the fuses during the run, on account of overload or of weakness in the fuse. The remaining instruments on each feeder are a voltmeter, a No. 1 switch-board converter and a 150 amp. type "E" compensator. When both feeders were run from one alternator, one voltmeter was connected to the genera-



BANK OF 10,000 VOLT TRANSFORMERS.

tor and the other to the feeder, and in this way the amount of compensation could be watched.

The oil-transformers were tested before shipment with 20,000 volts between the line-coil and the core and were then taken out of the oil and boxed. In order to expel any moisture which might have been absorbed by the insulation of the coils or have condensed on the cores during their long journey, the transformers were connected in two banks of ten each, the line-coils of each set being connected in series to the generator, which was run at a reduced speed, and the secondary coils each short-circuited on itself. The coils were thus gradually heated to a point somewhat above the boiling point of water, which at that elevation was about 201 deg. F. They were kept at this temperature for a short time and then paraffine oil of a special grade ("Diamond") was poured slowly into the boxes at the edges so that the coils would begin to absorb oil at their lower ends, and thus drive upward the air and volatile gases occluded by the insulation. The transformers were then again brought to their former temperature, which caused expansion and partial expulsion of the air remaining in the insulation. Some of the air would however collect under the insulation at the top of the coils, and had to be freed by mechanical agitation, produced by stirring the folds of insulation or by pounding on the boxes. The heat caused volatilization of some of the lighter elements of the oil, these coming to the surface as bubbles, just as the air did at first, and the agitation was kept up at intervals until bubbles from this cause also were entirely eliminated.

The 20 transformers were then connected as they would be when in regular use, and the two terminals of the line-coils, which were to give 10,000 volts, were connected in series with one hundred 100-volt lamps, which were then brought to full candle power, showing that the transformers were all in good condition. A similar test was then made at Pomona at the end of the 14-mile transmission line running to that place, after which the transformers there were prepared for work in the same way as at the power-house, except that the grouping and initial voltage were changed.

THE GUTTA PERCHA SUPPLY.

Mons. Hourant is making a determined and commendable attempt to put an end to the outrageous destruction of gutta percha trees which has so long been allowed to continue. He proposes to export the leaves of the tree and subject them to a special process which gives an excellent quality of pure gutta percha. The *Sarawak Gazette* says on this subject: "After some difficulty in getting natives to work systematically at the collection of the leaves, which had hitherto been looked upon by them as possessing no value, Mons. Hourant is now exporting leaves in quantities which increase month by month, and has erected a factory in Kuching for the purpose of thoroughly drying them before shipment. The advantages of this method of obtaining such a valuable product as gutta percha are evident. The native plan of cutting down a tree to obtain the sap was wasteful in the extreme. It has been estimated by carefully experimenting that an adult tree of 25 to 30 years of age yields of *pure dry* gutta only one catty; as much can be obtained from two pluckings of the leaves of a tree, without injuring it, and it will long continue to put out fresh foliage, and, what is more important still, will live to seed and reproduce its species; and the better kinds of gutta tree do not fruit until 30 years of age. The average gutta tree of 60 centimetres circumference at 5 to 6 feet from the ground was found to yield, by the native process, only ⅞ths catty of pure dry gutta. This is not so good as the 7 to 10 per cent. by weight obtained from the dried leaves; also, the gutta obtained from the leaves is chemically pure and dry, which is more than can be said of much of the Dyak gutta found in the bazaars. The millions of trees already destroyed by the native gutta hunters are still of service to Mons. Hourant, as their stumps have sprouted out into numerous small shoots, much in the same way as an osier does, and though these stems are too small to produce gutta, their leaves are as good as those of an adult tree."

FRENCH ELECTRICAL COMPETITION FOR PRIZES.

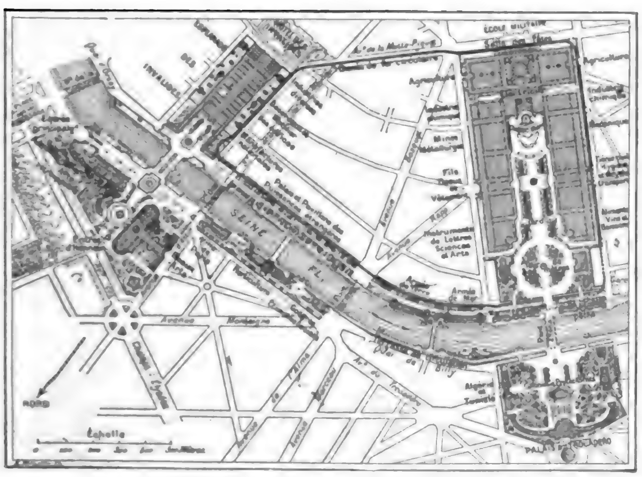
The Société d'Encouragement pour l'Industrie Nationale, Paris, offers some special prizes in the electrical industry and others. A premium of 2,000 francs will be awarded in 1896 for a small domestic motor, working independently or connected with a central station, and having an output of from 6 to 20 kilogramme-metres per second. This prize has already been awarded four times; on the first occasion to a hydraulic motor, on the second to a steam-engine, on the third to a gas-engine, and on the fourth occasion to a system of house-to-house transmission of power. It is now desired to vary the form and system of the motors, so that it would seem that the society is anxious to see what electricity can do in connection with its offer. A premium of 1,000 francs will be awarded in 1896, if it be earned, for a new alloy useful to the arts. The society is induced to hold out this prize for competition in view of the great results which have been achieved with aluminum, and of the possibilities that one or more of the newer metals may present means of forming a useful and successful alloy. A premium of 2,000 francs will be given in 1896 for an electric incandescent lamp using 0.05 ampere at 100 volts. The object is to obtain a lamp of small illuminating power running at a high voltage. The last prize is one of 3,000 francs, which is offered for bestowal in 1897, for a treatise embodying important improvements on the present methods of producing permanent magnets. Competitors should forward their schemes, models, etc., to the Secrétariat de la Société d'Encouragement pour l'Industrie Nationale, rue de Rennes, 44, Paris, before December 31 of the year preceding the distribution of the premiums.

THE PARIS EXHIBITION OF 1900.

Some idea of the magnitude of the exhibition that is to be held in Paris in 1900, may be gathered from the full report just issued by the general commissioner, M. Alfred Picard, who has been engaged for some time past in sifting the numerous proposals that have come from all parts of the world. Not a few of these projects are very ingenious. But it must be confessed, that by far the greater number are either impracticable or absurd. Nevertheless, they afford plenty of ideas that may be developed, and put into shape later on. And they promise to make the *fin de siècle* exhibition, worthy of the century's progress in art, science, and industry that it is intended to illustrate.

For the moment the Commission is chiefly concerned in deciding upon the main lines of the exhibition; the laying out of the grounds; the arrangement of the buildings, and the principal features that are to give the key-note to the whole enterprise. To secure the best possible results the Commission has incorporated many of the most promising features of the 108 plans that were submitted to them.

The site upon which the exhibition will be laid out has an area of about 320 acres. It includes the whole of the Champ de Mars, the banks of the Seine, and the space lying between the Champs-Elysées and the river. The whole of this vast area is to be cleared of the existing edifices with the exception of the Tour Eiffel, the Trocadero, and the Machinery Hall, which last building will, however, only occupy a secondary place in the general arrangement. It was at first proposed to do away with everything belonging to the last exhibition of 1889, but it was at last decided to leave the three principal edifices standing, the more so as the pulling down of the Tour Eiffel would involve considerable expense, while an enormous indemnity would have to be paid to the company owning it. None of the proposals for altering the aspect of the tower are satisfactory, and it is thought advisable to let it remain as it is.



PLAN OF THE GROUNDS AND BUILDINGS, PARIS EXHIBITION OF 1900.

An important landmark will, however, disappear in the Palais de l'Industrie which will have to come down to allow of the carrying out of one of the most interesting schemes of the exhibition. The principal entrance will be at the Place de la Concorde, that is to say, almost in the very centre of Paris. This will have an imposing facade, and will be in harmony with the general scheme of the exhibition. Once inside the exhibition the visitor will find himself in a long avenue, sheltered by trees, on the left of which, will be the Seine, and on the right two groups of buildings; one, devoted to the administration, to a retrospective exhibition of the arts, and to instruction, and another, to the Beaux Arts, upon which all that is best in French architecture will be lavished.

Between these two groups, and cutting the avenue in two, will be a wide and spacious boulevard, running from the Palais de l'Elysée to the Mansart cupola. It will cross the Seine by means of a bridge which will be one of the most striking features of the exhibition. Designed upon very picturesque lines, with a single span, it will be constructed entirely of steel, and will have a width of 60 meters, the same as the boulevard, and it will be laid out with gardens and terraces. The perspective formed by this boulevard with the Palais de l'Elysée at one end, and Mansart cupola at the other, will be one of the finest in Europe.

Between the Pont des Invalides and the Pont de l'Alma palaces will be erected on each side of the river, one group for the foreign Powers, and the other for the city of Paris, an exhibition of horticulture, and social economy. Terraces will also be laid out along the Seine with gardens and statuary, and the effect of these long lines of rich and picturesque buildings will be remarkable. It is intended to make great use of the Seine for decorative purposes, and at night Venetian fêtes will be held, when the gondolas and the illuminations of the palaces reflected in the water will give one the impression of the Grand Canal of Venice.

The Champ de Mars will be given up to manufactures and industries. It is here that will be found the great attraction of the exhibition. Upon the site of the plaster statue of the Republic, just in front of the machine gallery, will be erected a magnificent Palace of Electricity which will dominate the whole grounds. The exhibition is to be an apotheosis of electricity that will mark the beginning of the new century. No other power but electricity will be used in the grounds. Before this palace will be a fountain, and then a series of gardens will be stretched away to the Tour Eiffel. Upon either side will be the different annexes devoted to agriculture, mining, metallurgy, industrial chemistry, textile products, scientific instruments, alimentary products, etc.

These different sections will be laid out in straight lines with plenty of space between them, and the exhibits will be so arranged that visitors will be able to see the whole process of manufacture at a glance in each group. A sort of elevated railway will pass through every building and communicate with each section to permit of visitors seeing the whole of this part of the exhibition without trouble. The Trocadero will continue, of course, to play an important part, since for decorative and illuminating purposes it is unrivalled. In the area covered by these grounds will be seen the products of the French colonies, and a special annex will be reserved for Algeria and Tunis. So much for the general lines upon which the Exhibition will be laid out.

As for the special features, about fifty proposals have been selected for further consideration, out of the mass of schemes submitted to the Commission, and, by a shifting process, they will no doubt be eventually reduced to something like half a dozen. M. Francois Deloncle, the well-known deputy, is anxious to construct a telescope that will bring the moon to within a few miles of the observer; M. Camille Flammarion, the celebrated astronomer, wants to see an enormous sphere representing a satellite around which the public can be taken in balloons; and M. Pascal Grousset, whose thoughts turn in a different direction, points to the scientific advantages that might attend the exploring of the centre of the earth, or at least as near the centre by a few thousand miles as it is possible to get, by driving a hole, down which visitors of a curious turn of mind could be taken. This scheme has already been described in THE ELECTRICAL ENGINEER. Whatever may be the proposals selected they are certain to be of a very novel character, as the Commission is anxious above all to strike a note of originality. In such a vast exhibition special attention is naturally being given to the question of transportation, and this will be provided mainly by an electric railway which will run all round the grounds, while some of the railway companies will run trains right into the exhibition. It is to be feared, however, that the transportation facilities both in and out of the exhibition will fall very short of the needs of the enormous influx of visitors.

The estimated cost of the exhibition is \$20,000,000, of which \$14,600,000 will be spent upon the buildings. It is proposed that \$4,000,000 shall be paid each by the State and the Municipal Council of Paris, and that the rest shall be raised by the issue of sets of twenty tickets, that shall not only allow of admission to the exhibition but shall give advantages in the way of reduced fares over the railroads and admission at a cheap rate into the places of amusement.

MR. W. H. PREECE AND HIS TIRELESS SLAVE.

The *New York Times* in a recent very interesting column on electrical advances, has the following neat little item of gossip:

What between electric cooling fans and electric heating devices, we shall soon be able to take any kind of weather provided by the Meteorological Department, either in summer or winter with perfect equanimity. W. H. Preece, the well-known English telegraph chief, dwelt, in a recent address, on the extent to which the creature comforts of this generation are being increased by electric heating. During the last winter he had his office kept constantly at 60° Fahrenheit, a temperature which the Englishman considers ideal in cold weather, and all through the exceptionally severe winter his office was always comfortable, and its air was always fresh and wholesome, thanks to his electric radiator. Mr. Preece gave a humorous account of some of his experiences in domestic electric heating and cooking. In his own house he has an electric oven, and the dishes cooked in it are a perpetual pleasure. On his breakfast table is an electric warmer that keeps the breakfast dishes hot. Curiously enough, he had the warmer fixed almost solely to accommodate his boys, who would invariably lie in bed in the morning, and always come down to a cold breakfast. After vainly trying for years to break them of this bad habit, he got the electric hot dish, so that at all events the meal might be kept warm. The hot plate kept the dishes in perfect order, but as showing the contrariness of the boyish race, the moment the boys lost the charm of the cold dishes, they came down punctually to breakfast, and, in fact, since that time he has been the last and they have been the first.

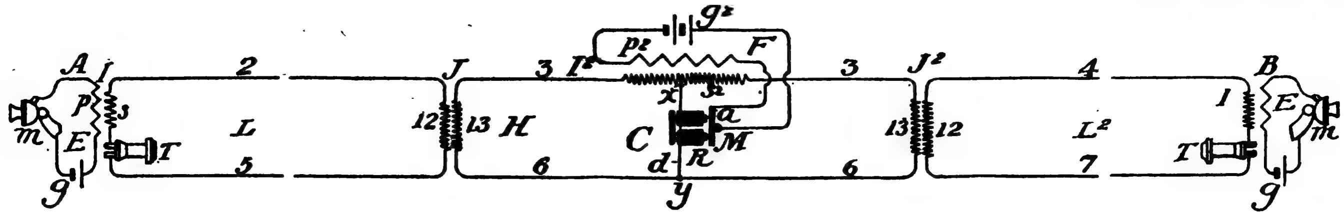


Fig. 1.—The Arnold Telephone Relay System.

THE ARNOLD TELEPHONE RELAY.

Notwithstanding the ill success of inventors in the past in their efforts to devise a telephone relay, work in this department is by no means being neglected, as evidenced by a number of patents issued last week to Mr. Chester H. Arnold and Mr. W. L. Richards, all of which are assigned to the American Bell Telephone Co.

Among these the patent of Mr. Arnold, No. 554,918, is typical of its class and of a large line of development in the same direction, and we therefore give a description of his relay illustrated diagrammatically in the accompanying engravings.

The essence of the invention consists in associating the relay or repeating apparatus proper, including its local repeating-circuit, with a short but conductively-complete auxiliary section of the main line, and in combining the section and its associated repeater mechanism and arrangement with the two main telephone circuits which are desired to repeat into each other, in such a way that it is inductively connected with both by means of repeating induction-coils, and thus constitutes a link connection between the two main circuits, uniting them into a single compound circuit for through communication. At the same time the balance is much facilitated by reason of the shortness of the complete middle-line section thus interposed at the central, intermediate or repeating station between the ends of the two circuits concerned.

In Fig. 1, which indicates the simplest exemplification of the invention, A and B, are sub-stations at the outer ends of the telephone circuits L and L^2, and C is an intermediate or repeating station entered by the other end of both circuits.

At the terminal stations A and B is the ordinary sub-station apparatus, consisting of a receiving-telephone T, a variable-resistance transmitter m in the local circuit E of a battery g, and the transmitter induction-coil I, whose primary winding is in the local circuit and whose secondary winding is in the main circuit.

At the central station C is a short closed circuit H, forming the link for through communication interposed between the main circuits L L^2.

Extended between the two conductors 3 and 6 (which are virtually continuations of the conductors 2 and 5 of circuit L on one side and of the conductors 4 and 7 on the other) is the bridge-conductor d, containing the receiving or repeating electromagnet R of usual construction. The armature or diaphragm a of this magnet carries the variable-resistance medium of a repeating transmitter M, and controls the same, the medium being placed in a local repeating-circuit F, including also a reinforcing-generator or battery g^2.

An induction-coil I^2 is interposed between the local circuit F and the central-station section H of the main line, and by its instrumentality the variations of current occurring in the local circuit are impressed in reinforced magnitude upon the main-line section. The long and fine wire secondary winding s^2 of the induction-coil I^2 is placed in the circuit of the main-line section H and is split or divided by the bridge connection at x, so that one-half of the winding is on each side of the bridge connection. The single or undivided coarse and short wire primary winding p^2 is in the local repeating-circuit F.

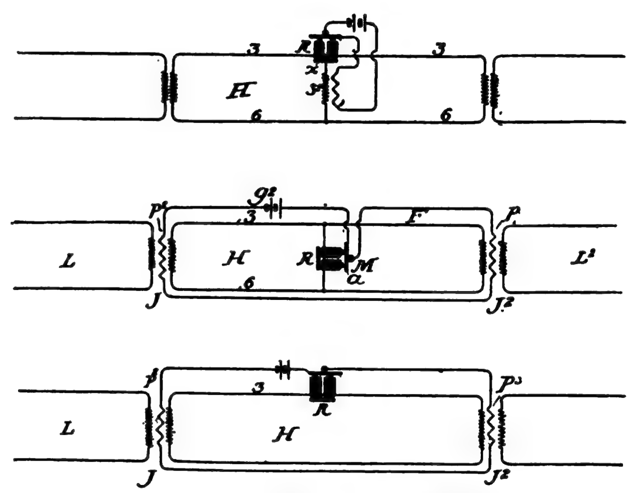
It only remains to describe the means of effecting the connection between the conductively-closed repeating-station section H of the main circuit with the principal or interstation-sections L and L^2. To this end there are interposed repeating induction-coils J and J^2 between the two ends of the station-section H and the central-station ends of the principal sections L and L^2, respectively, one winding l^2 of both coils being in the section H and the remaining winding l^3 of one of the repeating-coils J being in the section L, while the winding l^3 of the other repeating-coil J^2 is connected in the section L^2. The repeating-coils J and J^2 may be constructed on any preferred plan, provided only that the two windings have similar proportions as to length and size of wire, and provided that the windings are so relatively disposed that their mutual induction is at a maximum, so that the currents induced by either in the other is of like potential. This is necessary because transmission is reciprocal and because, therefore, that winding which at one moment is in a circuit which is receiving may at any other moment be in a transmitting-circuit, as the direction of conversation changes.

By the introduction of a short conductively-complete repeating-station section of main line connected with the two principal sections by repeating-coils it becomes possible to equalize the two sides of the electrical balance with great facility and substantial accuracy, first, because they can be made exactly of the same length, and, second, because they are both short.

Fig. 2 shows the same essential elements as are found in Fig. 1. The differentiating feature is the transposition and rearrangement of the repeating-magnet and induction-coil. In Fig. 2 the receiving-magnet is placed in one of the conductors 3 of the office main-line section H, one-half of its winding or one of its spool-helices being placed on either side of the point x of the bridge connection, while the secondary winding s^2 of the induction-coil remains undivided and is connected as a bridge between the conductors 3 and 6 of station main-circuit section H. There is no material change in the mode of operation.

In Fig. 3 the separate repeating induction-coil I^2 is dispensed with, and the local repeating-circuit contains two coarse-wire windings, one associated with the two windings of each of the two main line repeating-coils J and J^2, so that the coarse wire winding p^2 serves as a primary for the coil J, while the winding p^3 serves as a primary helix for the coil J^2. In this way the repeating coils J and J^2 are enabled to replace the repeating induction-coil I^2, so that when the transmission is from L to L^2, J^2 acts as the repeating induction-coil I^2, while when the direction of transmission is reversed the coil J acts as the repeating induction-coil.

In Fig. 4 the special bridge is dispensed with, the repeating magnet R being placed in one of the conductors 3 or 6 of the repeating section of the main-line section, and the division of the local repeating-circuit primary winding into the two sections p^2 and p^3, and their association with the two repeating-coils J and J^2, is relied upon for the establishment of the requisite balance. This arrangement may in some cases be convenient, but is deemed in some respects inferior to those already described.



Figs. 2, 3 and 4.—The Arnold Telephone Relay System.

TELEPHONE NOTES.

Middletown, N. Y.—A call for 25 per cent. of the capital stock of the new Orange County Telephone Company has been made.

Creede, Col.—At a meeting of a majority of the stockholders of the Creede & Bachelor Telephone Company it was definitely decided to build the proposed telephone line to Bachelor.

Philadelphia.—The Delaware and Atlantic Telegraph and Telephone Co. has passed into the entire control of the American Bell, along with the Bell Telephone Co. of Philadelphia, as noted recently. It reaches 150 towns and has about 4,000 subscribers. The Philadelphia company has over 6,000 subscribers.

Detroit, Mich.—The Detroit Harrison telephone company has been organized, the incorporators being O. W. Shipman, Charles P. Collins, R. A. Brett, Albert Pack, Collins B. Hubbard, Frank D. Andrus, William L. Holmes and Charles Flowers. The capital stock is $600,000.

ASHLAND, WIS.—The Wisconsin Telephone Company will soon have a metallic line connecting Ashland, Washburn and Bayfield.

ROCHESTER, N. Y.—The Wayne Telephone and Telegraph Company is being organized with a capital stock of $5,000.

RENVILLE, MINN.—The Renville Telephone Company will construct a loop, and, in addition, will construct a line to Olivia, the new county seat.

DECATUR, ILL.—If the people will put up the money, the Municipal Telephone Line will be extended to Dalton City and intermediate points at once.

HUDSON, N. Y.—The Hudson River Telephone Company has purchased the old Mutual telephone line between this city and Poughkeepsie.

HILLSBORO, ILL.—The Montgomery County Telephone Company has been formed; capital stock, $8,000; incorporators, Chas. A. Ramsey, Jacob J. Frey and William S. Barry.

BALTIMORE, MD.—The name of the Writing Telegraph Company was changed to the Home Telephone and Telegraph Company by an amendment to the charter.

ATHENS, MICH.—The Southern Michigan Telephone Company, which has its headquarters at Athens, now has thirty-five towns connected by wire.

CONWAY, IA.—Articles of incorporation have been filed by the Conway Telephone company with $5,000 stock in 50 shares. The officers are: President, Arthur Haynie; secretary, Miles H. Simmons.

CANTON, ILL.—The Citizens' Telephone Company, of Canton, with double the service now given, has made a proposition to furnish the city with five telephones or gongs, or both, for $100 per year, and all additional instruments at the same rate—$20 per year.

HENDERSON, KY.—The Harrison Telephone Company is in a very prosperous condition. The exchange here will be ready by July 25, and subscribers will be able to use their telephones shortly after that time.

HARRIMAN, TENN.—The Directors of the Mutual Telephone Company have perfected their organization by the election of the following officers: Dr. C. T. Cory, President; J. D. Buck, Vice President; E. C. Drowne, Secretary; W. H. Julian, Treasurer.

MERRILL, WIS.—The Merrill Telephone Company has filed articles of incorporation with the secretary of state; capital $100,000; incorporators, H. H. Foster, H. R. Freeland, C. A. Norway, Julius Thielman and W. H. Flett.

ALAMEDA, CAL.—A new telephone company, entitled the Commercial Telephone Company, has been incorporated to do business in the county of Alameda. The directors are E. R. Smith, Albert L. Stetson, J. D. Johnson, John W. Butler and S. P. Lunt. The capital stock is $100,000, divided into 1,000 shares of $100 each.

HAMILTON, O.—The stockholders in the Bethany and Hughes Telephone Company have held a meeting for the transaction of business. Steps were also taken towards having the company incorporated under the name of the Hamilton-Hughes-Monroe Telephone Company, with a capital stock of $5,000.

WILMINGTON, N. C.—The Inter-State Telephone and Telegraph Company, of Durham, N. C., has asked for a franchise. The building of the system will result in an outlay of about $10,000 in and around Wilmington, and from $75,000 to $100,000 will be expended in the State.

JERSEY CITY, N. J.—Agents who claim to represent a new telephone company that will compete with the New York and New Jersey Company—are canvassing the city for subscribers. They offer to give service on the unlimited line for $48, but to secure this low tariff, subscribers must sign a contract for three years.

CARTHAGE, MO.—The Carthage Electric Telephone Co. is incorporated with T. J. Clark, president; E. R. Wheeler, vice-president and treasurer, and George E. Wheeler, secretary and general manager. This company has purchased the franchise of the American Telephone Co. in Webb City, Carterville and Carthage.

LANSING, MICH.—An order for 400 instruments and necessary equipments for the new telephone company has been placed with the Western Telephone Construction Company. The cedar posts have been ordered and it is expected that work will be commenced on construction this week. The manager expects to have the line in working order by the 1st of August.

CREEDE, COL.—At a regular meeting of the City Council an exclusive franchise was granted the Creede and Bachelor Telephone company. The action of the Creede council will precipitate a fight between the Creede-Bachelor company and W. C. Munsell, who was granted an exclusive franchise for five years by the town of Bachelor, and neither can enter the other's town unless they consolidate.

TRINIDAD, COL.—The City Council has granted a franchise to a company composed of business men of the city to establish and maintain a telephone system in Trinidad.

DETROIT, MICH.—Two 30-year telephone franchises have passed the council; one to the Harrison, the other to the Brown Loud Speaking Telephone Companies.

ELWOOD, IND.—The Pana Telephone Company has sold out to the Elwood Telephone Company, and all litigation between them has ended.

HONESDALE, PA.—The Citizens Telephone Company are pushing along the work of putting up poles and stringing wire. The wire is already up between Carbondale and Honesdale.

SPRINGFIELD, MO.—The Dunlap Construction Company has completed the line of the Christian County telephone company. This line connects Springfield with Ozark, Linden, Sparta and Chadwick.

SACRAMENTO, CAL.—The Board of Supervisors has granted a franchise to the Capitol Telephone and Telegraph Company to place its wires throughout the county. The company will introduce a new telephone service in this city early in July.

HARRIMAN, TENN.—The stockholders of the Harriman Mutual Telephone Company have adopted the Strowger system with automatic switchboard, and perfected plans for the erection of the line.

LENOX, IA.—A telephone company operating at Lenox and Clearfield has petitioned the city council for the right of way into Creston, to put up poles and wires. The council gave them the privilege.

CHESTER, ILL.—The Chester Mutual Telephone Exchange has been formed, without capital, to operate a telephone exchange on mutual plan; incorporators, George I. Ray, V. Steber, William R. Mackenzie.

GRAND RAPIDS, MICH.—President Fisher and Manager Ware have now raised $60,000 of the $80,000 capital stock wanted for the Citizens' Telephone Company and are hustling for the rest.

MONTPELIER, IND.—The Montpelier telephone company has been incorporated with a capital stock of $20,000. The shareholders are John Burns, W. N. Pay and Jerry Hayes, all of Montpelier.

DETROIT, MICH.—The Common Council has passed the Harrison Telephone Company and the Brown-Loud Speaking Company's telephone ordinances, amended so that the companies shall be compelled to place their wires underground within the half mile circle for the present.

ALTOONA, PA.—The success of the new telephone company is practically assured. It is said that Councils will grant the franchise permitting them to string wires over the city, and the charges will be $2.00 per month for a business house and $1.50 for private residence per month.

MASON CITY, IA.—The new city telephone system is to be put in by the Phoenix National Telephone Company of Indianapolis, Ind. The rentals are made very low, $2 a month for business houses, $1.50 for residences, and $3 where both are taken by the same subscriber.

NIAGARA FALLS, N. Y.—A number of local business men have interested themselves in the new automatic telephone, which is being shown at present at room No. 6 in the Arcade, and the outcome is that a local telephone company is about to be organized. The company will be known as a branch of the Mutual Automatic Telephone Company.

TOLEDO, O.—The Central telephone conduit ordinance has been adopted by the board of aldermen. Work will be begun on the conduits just as soon as the ordinance is signed by the mayor. It will be one of the most complete systems of underground wires in the world. One of the finest switchboards made will be used in the exchange. This will cost $100,000.

WILMINGTON, N. C.—The North Carolina State Telephone Company has been organized with L. H. Carr of Durham as president. Three thousand miles of wire have been ordered, and Wilmington, Winston, Raleigh, Goldsboro, Durham, Greensboro, and Charlotte will be connected. It is intended eventually to include all the principal towns in North Carolina and South Carolina in this long distance system.

NILES, MICH.—The city council has given the Bell Telephone Co. a respite, in order that they may consent within that time to annul their contracts with various companies who were compelled to drop the Gilliland phones. The general manager of the Bell company, F. A. Forbes, and an attorney from Detroit, H. E. Boynton, have visited Niles, and announce their intention of giving the city a warm legal fight if the latter attempts to remove their property.

ELECTRIC TRANSPORTATION DEPARTMENT.

BOSTON ELECTRIC MAIL CARS.

BY W. S. KEY.

The various branches and ramifications of the West End R. R. system, which reach not only any part of Boston proper but extend out, like a spider's web, to almost any point in the extensive suburban district, presented an admirable opportunity for abbreviating the time hitherto occupied in distributing the mails between the chief post office and the sub-offices on the outskirts. Realizing this fact, negotiations were opened between the Mail

THE BOSTON ELECTRIC MAIL CARS.

Department and the Directors of the West End R. R., which resulted in a contract being placed for the building, equipping and operation of a certain number of cars. Thereupon the West End Co. proceeded to change or reconstruct eight ordinary 16-foot box cars, and to adapt them in every way to the service for which they were intended. The interior was fitted with a number of pigeon holes as in the mail cars on the steam roads, and sorting counters are placed along the sides of the car in front of the pigeon holes. There is also an iron frame on which to suspend

INTERIOR, U. S. TROLLEY MAIL CARS, BOSTON.

the mail sacks with open neck so as to receive the matter belonging to them. Overhead is a roomy rack into which are thrown the empty sacks after the mail has been removed from them. To all intents and purposes the cars are a diminutive duplication of the regular railway mail car.

In reconstructing these cars a door was built on each side, the rest being boxed in; no other change being necessary. They are painted white picked out in gold, the lettering being done in red and gold, which makes the cars look very conspicuous and attractive on the street.

The dashers are made solid on opposite sides, the off side being closed by a Wood patent gate. The end doors are permanently closed, admission to the inside being alone gained by the side doors. Each car is equipped with two General Electric motors of 25 H. P. capacity each, the controllers being of same make.

These cars are run on a one hour schedule to and from five different localities, collecting and distributing mail sacks en route. One car runs on a cross town route, between suburban offices, and one car is kept for night service. It is expected that ere long some of the larger cities that are connected by electricity with Boston will have at least part of their mails carried over the electric railway, for the service, since it was inaugurated a month or two ago, has given such unbounded satisfaction, and has effected such a saving of time, that the public is loud in its praise. Each car runs about 40 miles a day, beginning between five and six A. M. and continuing until nearly eight P. M., when the night service begins. There is one mail clerk to each car and motorman and conductor. Of course the Post Office Department furnishes the clerk, the motorman and conductor being West End men.

As yet there has been no failure to make time according to schedule, and by Fall it is likely there will be many more similar cars in operation in the vicinity of Boston.

THE MORRIS AND SALOM ELECTRIC CARRIAGE IN PHILADELPHIA.

The first electric carriage on the streets of Philadelphia was put in operation on August 31, 1894, since which time it has been in constant use, except during the winter months, having travelled several hundred miles without any serious mishap or accident, all over the streets of Philadelphia, some of which are in very bad condition, and through parts of Fairmount Park.

The carriage, which we illustrate in the accompanying engrav-

THE MORRIS AND SALOM ELECTRIC CARRIAGE, PHILADELPHIA.

ing, was designed by the gentlemen occupying the seat, Mr. Henry G. Morris and Mr. Pedro G. Salom. Its total weight, including the battery, without passengers, is 4,250 lbs., the battery weighing 1,600 lbs. The maximum speed obtainable is 15 miles an hour and the maximum mileage on one charge 50 to 100 miles, according to speed and grades. Sixty cells of 100 ampere hour capacity are employed, having 13 H. P. hours capacity at the maximum discharge rate.

The motor is of the electric launch type, 3 H. P. nominal, built by the General Electric Co., and capable of developing, for a short time, 9 H. P., and weighs 300 lbs. It is connected through a pinion on end of the motor shaft to a countershaft having a balance gear to enable the wheels to move independently in turning curves. At the ends of the countershaft are pinions gearing

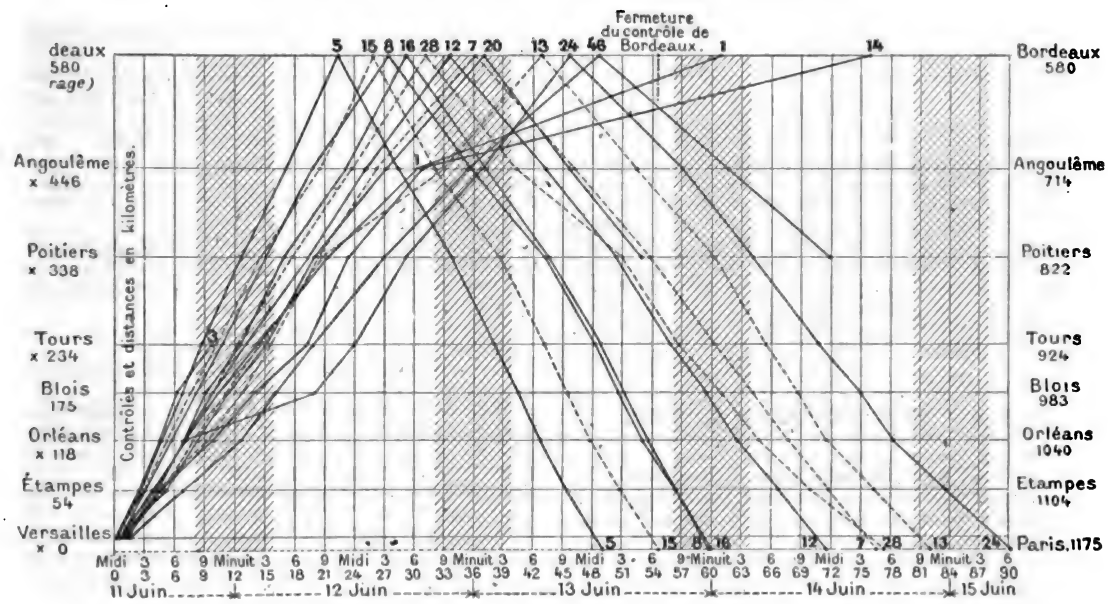


FIG. 3.—CHART SHOWING RECORD OF SELF-PROPELLING VEHICLES, PARIS–BORDEAUX RACE.

into large gears attached to the rear wheels of the wagon. The front of the wagon rests upon a fifth wheel of 30 inches diameter, which is attached by an iron frame to the rear axle. The lower half, and revolving part of the fifth wheel, rests on the springs between it and the front axle. This fifth wheel turns on hardened steel balls, being moved by a pinion and shaft with suitable reducing gear, which is operated by means of the hand wheel on top of the shaft, thus securing ample power as well as facility in steering. The controller regulating the current is placed in front of the foot board and is operated by shaft and crank immediately below the steering wheel.

This wagon was built merely to gather experimental data on the amount of battery and power required to drive over ordinary roads, and Messrs. Morris and Salom now have designs completed, based on the knowledge thus gained, which will make the new vehicles very much lighter for the various purposes for which they are designed. The present vehicle has a seating capacity for six, but there is ample power, if the seats were provided, to carry from 12 to 15 people.

THE PARIS-BORDEAUX SELF-PROPELLING VEHICLE CONTEST.

The recent remarkable performances of self-propelling vehicles in the prize competition over the road from Paris to Bordeaux and return, last month, has attracted attention deservedly to this method of propulsion. As a direct result of this competition, we noted last week a similar one just organized by the *Times-Herald*, of Chicago, to be competed for over the roads between Chicago and Milwaukee, while the announcement is also

FIG. 1.

made of a like contest organized by the London *Engineer*, with prizes aggregating 1,000 guineas.

The French competition was taken part in by no less than twenty-two vehicles, twelve of which arrived at Bordeaux within the limit of time set by the rules of the competition, and nine of these covered the distance of nearly seven hundred and fifty miles in less than one hundred hours. Of these nine carriages eight were driven by petroleum or gasoline motors, and a single one, that of M. Bollée, built in 1880, used steam. In describing the outcome of this contest, M. E. Hospitalier, in our excellent contemporary, *La Nature*, refers to the result as the incontestable and uncontested triumph of the gasoline motors, and as removing all doubts of the endurance of self-propelling vehicles.

The carriage which came in first in the race, illustrated in

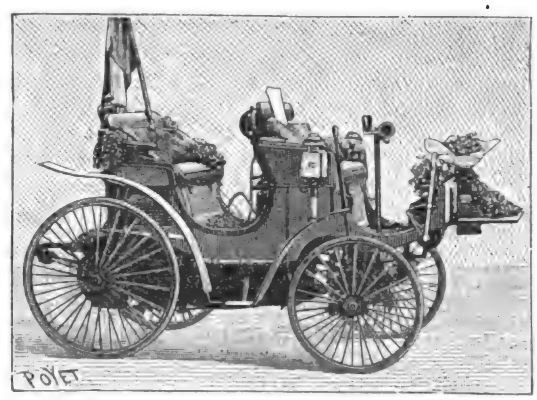

FIG. 2.

Fig. 1, was built MM. Panhard & Levassor, but did not receive first prize, as, according to the rules of the contest, the first prize was to be awarded to a carriage capable of holding four persons, or more. The first prize of 31,500 francs was awarded to the carriage illustrated in Fig. 2, which came in fourth in the race, and whose record is shown at line 16 in the chart Fig. 3, which shows graphically the result of the contests, the winning carriage being designated as number five. This graphical record shows in detail the principal incidents of the race, and the greater or smaller regularity in the pace of the carriages. Thus it will be seen that the last carriage arrived at Bordeaux almost at the same moment that the winning carriage No. 5 arrived in Paris, having made the record of 750 miles in 48 hours and 48 minutes. All the engines driven by gasoline motors which won prizes, show a perfectly characteristic curve, representing an inverted V, being the more regular the more uniform their speed, and the angle of the V being more acute the greater the speed. In this respect the record of No. 5 is irreproachable. In the chart the time elapsed is plotted as abscissæ, and the distances are as ordinates. The curves 1 and 3 are those of the steam carriage of M. De Dion, and No. 14 that of the bicyclette of Duncan & Suberbie, and No. 20 that of one of the steam carriages of M. Serpollet.

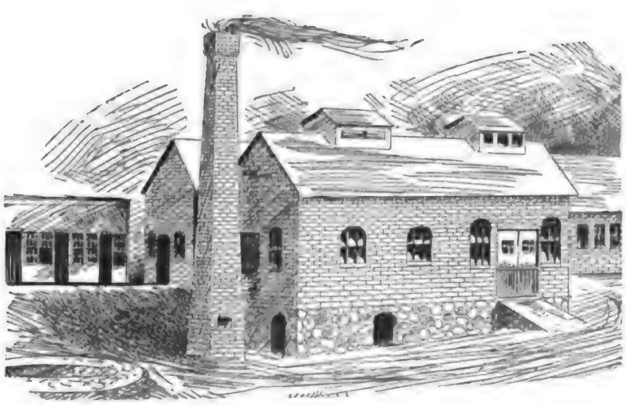
The results of this contest seem to show that the lightest vehicles proved best on the road, and this fact proves the superiority, according to M. Hospitalier, of gasoline and of essence of petroleum over every other known motive power. As a matter fact, other things being equal, it requires only .88 lb. of gasoline to pro-

duce 1 H. P. hour, whereas steam requires at least 6.6 lbs. of coal. As to storage batteries, according to M. Hospitalier, it would require more than 220 lbs. to obtain the same power during the same time. Light vehicles also allow of taking advantage of the employment of rubber tires; all the prize gasoline carriages were so equipped, and one, No. 46, was equipped with pneumatic tires, and covered the route of seven hundred and fifty miles without an accident to the wheels, notwithstanding its weight of 2,880 lbs. The ball bearings also contributed, in a certain measure, to the success of the gasoline motors. All the high speed steam carriages met with accidents, which seems to indicate that their weight, made necessary by the system employed, deprives them of the requisite qualities of a carriage of this nature. The essence of petroleum referred to as the fuel used in some of the carriages, is a product having a specific gravity between that of kerosene and gasoline, being about 10% lighter than the former.

THE GLOUCESTER AND ESSEX RAILROAD.

Among the trolley roads put in operation this season is the Gloucester & Essex (Mass.) Railroad which has just started running and which claims special attention owing to the length of travel which it will afford when all arrangements have been completed with contiguous roads.

The plant is located at a point midway between the Essex Falls station and the road known as Western avenue. Between this thoroughfare and the new buildings, runs the Falls brook, a water way of considerable magnitude, which carries the surplus water from Chebacco lake and empties it into Ipswich river. Over this brook, a substantial and ornamental bridge has been



THE GLOUCESTER AND ESSEX R. R. POWER HOUSE.

constructed, and rails are laid thereon connecting with the main line which runs along Western avenue. It is from this brook that the water supply for the boilers and condensers of the new plant is taken.

The plant consists of three buildings, as shown in the accompanying engraving, first to the left being the office building, a single-story wooden structure of simple architecture, in which will be located the offices. Next comes the brick and iron car shed, 200 feet long by 50 feet wide. The walls of the structure are of brick. The roof is entirely composed of steel, the light-looking but strong trusses being covered with corrugated sheet steel. This part of the work, as well as all the other roofs, was done by the Berlin Iron Bridge Company of East Berlin, Conn.

Four tracks extend the whole length of the shed, and they are connected together by means of a transfer table. The shed is designed to house 30 cars.

At the right of the car shed, is the boiler house, 40 feet square, and similar to the first building in style of architecture and construction. Here are three boilers, each is of 125 horse power capacity with room for one more of equal size. The boilers are from the Edward Kendall, Charles River Iron works of Cambridgeport, Mass.

The power is furnished by two independent triple expansion tandem engines from Messrs. McIntosh, Seymour Co., of Auburn, N. Y., each of 325 horse power. They are set on solid foundation piers of brick. The three cylinders are of 23, 22 and 12 inch diameter, with a stroke of 22 inches. The fly wheels are eight feet in diameter and each weighs over two tons.

Upon the same shaft as the fly wheel is coupled a Walker generator. Each of these generators has a capacity of 250 K. W. One of these engines and generators will be ample to operate the road. Should business increase to such an extent as to render the combined power insufficient, other engines can be placed alongside by an extension of the house, which has been provided for.

The cars for the line are mounted on Peckham trucks and supplied with two 30 H. P. motors, manufactured by the Walker Mfg. Co., of Cleveland, Ohio.

An understanding had been arrived at between the managers of the road and the Lynn & Boston Railroad, whereby the Gloucester tracks are to connect with those of the L. & B. at Beverly, and cars will be run over the tracks of the latter company, and use its power clear to Town House Square in Salem. This will make one of the longest electric roads in the country, as it will be possible to make the trip from Gloucester to Boston, a distance of about 33 miles, entirely by trolley.

The roadway has been built and equipped by the Worcester Construction Company, of Worcester, Mass., the mason work on the buildings by S. A. Burnham, of Essex, and the carpenter work by Pitman & Brown, of Salem.

GOOD BRAKES THE THING NEEDFUL.

THERE is a good deal of force in the suggestion of THE ELECTRICAL ENGINEER that good brakes are more necessary to street cars than the indifferently successful fenders which are in use. It is not for lack of good and quick-acting brakes that the feeble and out-worn hand brakes are retained. The inventors have devised power brakes by means of which the motorman, by a slight movement of the hand, can stop cars at a high rate of speed; but the companies do not adopt the improved appliances, because they cost more than the old.—*Boston Transcript.*

OPENING OF THE DETROIT CITY RAILWAY.

Dr. H. A. Everett, vice-president and general manager of the Detroit City Railway, writes us that the road is now in operation, the first car having been taken over the road by Mayor Pingree, who wore a motorman's uniform. The Company has about 27 miles all constructed and is operating already about 15 miles. The franchise covers 55 miles of track in the city proper and about 9 miles in the immediate suburbs. The road bed is laid in concrete in accordance with the Canadian practice of Dr. Everett and his associates; and it is believed that maintenance will be very slight for a number of years. The best that can be bought has been put in, and expense has not been spared in any department. The cars in use are of the combination pattern similar to those in use on Euclid avenue, Cleveland. The motors are of the latest Westinghouse make. The rail was rolled by the Cambria Iron Co. The poles are entirely of iron, and the overhead system was laid out for economical operation with a 00 trolley wire; all the details being got out by the Cleveland Construction Co. The Company has built a very substantial brick power house 150 feet by 270, with a brick stack 12 foot flue and 250 feet high. The engines are direct connected, cross compound Allis-Corliss, two of 600 H. P. and two of 1200 H. P. with Walker generators and Stirling boilers. It is expected to have power from the plant by September 1, and to have the line under pretty fair operating conditions by November, with 75 regular cars in service. The Company sells 8 tickets for a quarter.

HIGHER TROLLEY SPEED FOR BROOKLYN.

The speed at which the Brooklyn trolley cars now travel the streets of that city does not meet with approval of many of the business men, who claim among other things that the cars do not run even at the rate of speed allowed by the new city ordinance. These business men assert that many of their customers complain of the slow transit; and besides this, their business is injured materially, and now the merchants intend to petition the Board of Aldermen to modify the ordinance.

The Mechanics and Traders' Exchange has also gotten up a petition asking the Aldermen to increase the rate of speed. In the petition they say: "We do not advocate indulgence in any policy which will permit cars to be operated at a reckless pace, thereby imperiling human lives, but we do hold that a reasonable rate of speed is not inconsistent with perfect safety. Cars without fenders are propelled as fast as nine and twelve miles an hour on the crowded thoroughfares of Broadway and Third Avenue, New York, and we think a speed of ten miles an hour outside the crowded sections of Brooklyn should be permitted."

WORCESTER TO SPRINGFIELD BY ELECTRIC ROAD.

There seems to be a good prospect for the connection of Springfield and Worcester by an electric road. Work is soon to be commenced on the extension of the Worcester and Spencer line to West Warren which is expected to be in operation early in the fall. It is also expected that Palmer will connect with Springfield this year by a line to Indian Orchard. This will leave but an eight mile gap between Palmer and West Warren to be covered to complete the connection of Springfield and Worcester. This electric road will for much of the way parallel the Boston & Albany steam road.

ELECTRICAL INSTALLATION, MOUNT LOOKOUT COLLIERY, WYOMING, PA.

An excellent example of electrical coal mine operation is the installation at the Mount Lookout colliery at Wyoming, Pa., where locomotives, pumps and drills are being successfully and economically operated by electricity. This plant was installed by the General Electric Company and all the electrical apparatus employed is of its manufacture.

The source of power is a McEwen high speed engine making 218 revolutions per minute. It is located in the power house—a brick building some 200 feet from the main shaft, and about 100 feet from the air shaft. Belted to this engine are two multipolar General Electric generators, one of 100 K. W. (135 H. P.) capacity, the other of 20 kilowatt (28 H. P.) capacity. Haulage, drilling and pumping in the mine are operated by current from the larger generator while that from the smaller is taken for the incandescent and arc lighting circuits on the surface. In case of accident to the larger generator, the current from the smaller one can be utilized for power purposes.

From the two skeleton switchboards in the power house the circuits are lead, one to the surface the other to the mine. The office, engine and boiler houses are lighted by incandescent lamps; the breaker and surrounding grounds by 2,000 C. P. arc lamps.

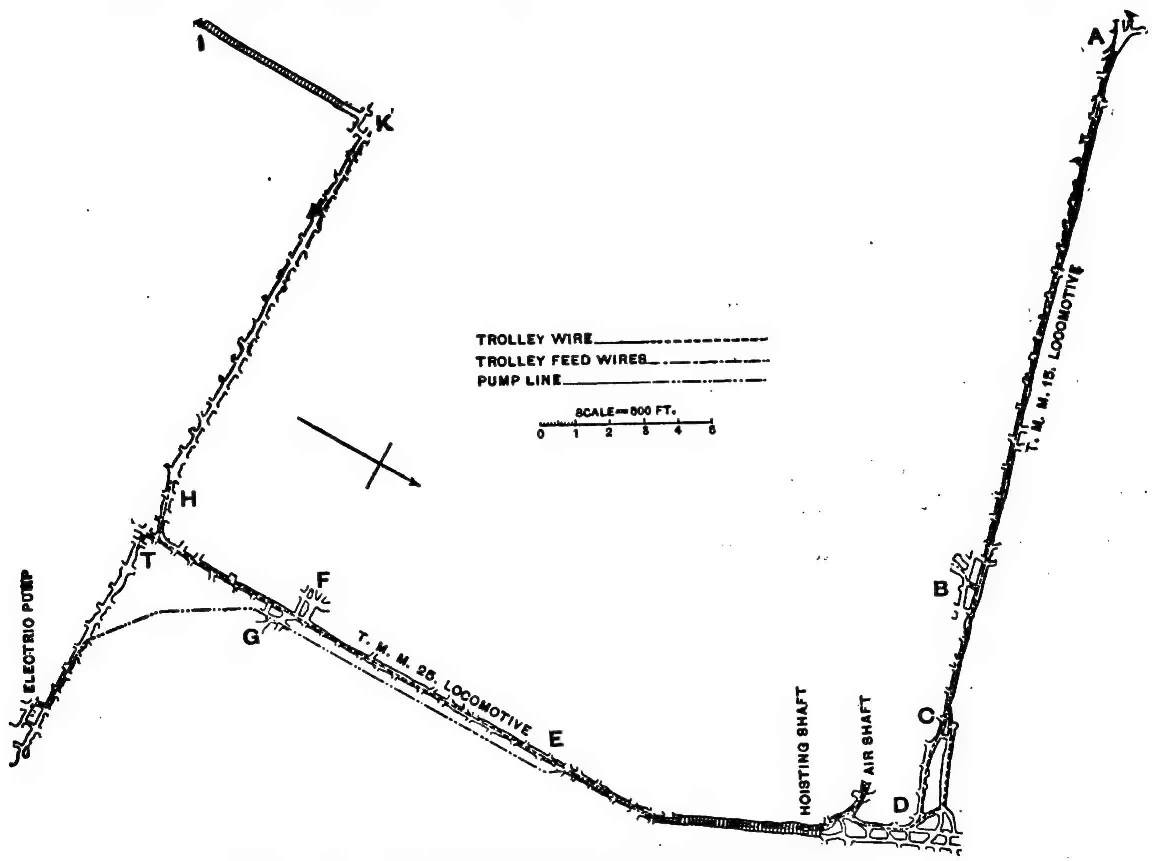
The conductors for the mine operations are strung 300 feet down to the bottom of the air shaft and consist of lead covered cables for the feeders and returns. The feeders are carried along the main gangways parallel to the trolley wire, or through old workings or air ways. The feeders are waterproof rubber covered copper wires strung on glass insulators attached to roof blocks.

At the bottom of the shaft the feeders divide, one branch supplying current to the North Workings the other to the South Workings. No. 0 hard drawn wire is used for the trolley wire the rails being bonded for the return. The trolley is suspended from oak roof blocks by a special mining ear which clamps the wire but is not soldered to it.

Haulage in the North Workings is effected by one electric locomotive which weighs about 6½ tons, equipped with two single reduction waterproof motors. It has a draw bar pull of 1,500 pounds on the level at 6 miles an hour, while at starting it will exert a pull of 3,500 or 4,000 pounds without slipping the wheels. The extreme dimensions of this locomotive are 11 feet 4 inches long, 57 inches wide and 34 inches high. The total length of the gangway over which it operates is about 2,800 feet, although including sidings and turnouts about 3,000 feet of trolley wire is suspended in the North Workings. The locomotive makes between 20 and 25 round trips per day. It is handling at present seven loaded cars, but is capable of easily hauling twice this number. The grades vary from the level to 2.8 per cent. and all are against the empties.

Haulage in the South Workings is effected by a locomotive equipped with two single reduction motors, and having a draw bar pull of 2,500 pounds on the straight level at a speed of 6 miles an hour. At starting, however, it can exert a draw bar pull of 4,000 to 5,000 pounds without slipping the wheels. The total weight of the machine is about ten and a half tons. It is 11 feet 4 inches long, 58 inches wide over all and 34 inches high. The maximum run made by this locomotive is about 1,200 feet, and the length of the wire used, including turnouts and sidings, is about 1,800 feet. At present this machine is hauling ten cars and making from 40 to 45 round trips pushing in the empties and hauling out the loaded cars. In starting from the entries F, G, H, and I where the trips are made up, the locomotive does its hardest work as there is a sharp grade and curve against the loaded cars. Each mine car empty weighs 3,000 pounds, and loaded 8,000 pounds.

The South Workings haulage line is to be extended from H to K and through a rock tunnel at L. The branches F, G and I will then be abandoned and the locomotive will then operate over about 3,500 feet hauling 400 cars per day from the head of the rock tunnel at L.



MAP OF ELECTRICAL CIRCUITS, MOUNT LOOKOUT COLLIERY, WYOMING, PA.

The electric pump is situated in the workings off the branch I. It is a standard duplex double acting piston Knowles pump operated by a General Electric motor, and has a capacity of 300 gallons of water against a 40 foot head. The piston speed is constant and should the water fall below the mouth of the suction pipe, the pump does not race. This pump has been in operation for more than a year, working twenty-three hours a day. It requires no attention except at starting and stopping, and an occasional oiling.

Two General Electric rotary coal drills are also in a low seam in the Southeast Workings of the mine. These are run from a circuit taken from that connected with the feeders in the main gangway. The length of this is about 1,400 feet. The drills are working a 3 feet seam of coal and taking up a 2 foot slate bottom. They make about 6 feet per minute with an inch and a half bit in the coal and 4 feet per minute in slate or "boney."

Since this electric plant was started it has operated without hitch or accident. Its installation has induced a decided economy in the operation of the mine, and is exciting considerable interest among coal operators, to whom it stands as an object lesson in the economical operation of mines.

EDITORIAL ANNOUNCEMENTS.

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Communications for the Editorial Department should reach it not later than Thursday. Copy for advertisements should be handed in not later than Friday.

THE OLDEST ELECTRICAL JOURNAL IN AMERICA.

VOL. XX. NEW YORK, JULY 24, 1895. No. 877.

CONTENTS.

HORSELESS VEHICLES.

THERE is perhaps no country in the world where art, science and industry are so much encouraged by the awarding of prizes for meritorious work and progress, as France; and although it might possibly be argued that no invention or appliance of the first order of importance was ever the direct outcome of a prize competition, still it is not to be denied that the origin of many advances can be traced to the stimulus of a prize competition. Even if such competitions do not always result directly in bringing out the desired improvement, they nevertheless draw attention prominently to the object in view and set to work many who would otherwise remain passive, if not in total ignorance of the needs of the times. We are led to these reflections in contemplating the results of the late self-propelled vehicle competition over the road between Paris and Bordeaux and return, which has attracted more than an ordinary amount of attention, and deservedly, as it touches so closely the question of cheap and rapid transportation. To look upon the results of this competition merely in the light of a race organized by wealthy amateurs with a fad is to ignore the philosophy of the history of transportation, and more particularly the most recent part of that history as embodied in the annals of the electric railway for the last ten years.

The horse has already been practically banished from the streets of American cities as a popular means of passenger transportation and gradually but surely the rest of the world will follow American example. But the highway and country road still afford an asylum to the horse; yet even here, as the recent contest in France has shown, he is not safe from competition.

The result of the race demonstrated the remarkable qualities of the petroleum motor over a course covering such a distance and must have been a disappointment to those who had cherished hopes for the success of the electric carriage which entered the lists. The result so far as the electric carriage was concerned might have been foreseen. We have never been accused of lukewarmness in advocating the adoption and application of electricity to any useful purpose suggested, but a consideration of all points involved leads us to the unavoidable conclusion that for *long distances such as those covered in the Paris-Bordeaux contest* the electric storage battery carriage is not yet available. As shown in another column, it requires 250 lbs. of battery and motor to produce one horse power hour, and handicapped in this fashion it is useless to pretend that the storage battery can compete with power directly applied by a prime mover weighing less than one quarter of the necessary electrical equipment. Granted even that a lighter form of storage battery may make it possible to reduce the weight; even the copper-alkaline cells would hardly reduce the weight of battery more than one-third. We have in the above comparison considered the electric storage battery carriage in the light merely of a long-distance traveller, but while compelled to admit its inferiority under such conditions, we are by no means ready to concede like superiority for the petroleum motor for the ordinary distances to cover which wagons are usually employed. After all, the French contest was a *tour de force* and it is doubtful if any one desirous of going from Paris to Bordeaux and return on business would dream of selecting the wagon road instead of the steam railway. To that extent, therefore, it is necessary to modify the opinion which one is apt to form at the start in studying the record given on another page. The first consideration in modern travel is comfort, and this holds true as well for short as for long distances. It is this requisite, aside from the question of speed, which has

made the stage coach and omnibus a memory in most civilized countries, and has given the electric car the popularity it enjoys. Granted, then, the conditions of short haul (which is the normal work of a road carriage), and maximum comfort, we are not alarmed for the future of the electric carriage. On the contrary, comfort being the first consideration in vehicles of this type the comparison as between a heat engine of any description whatever and the electric motor, becomes almost ludicrous. Far, therefore, from losing courage, those who are devoting their attention to the construction of electric carriages should redouble their efforts. The several recent designs of electric carriages actually constructed and the one illustrated in this week's issue give evidence of intelligent thought, and with the improvements suggested by their operation in practice, we may soon expect the creation of a regular demand for such vehicles. Nor must it be forgotten that there are other means of electric propulsion to which ordinary road vehicles are well adapted and that the trolley carriage fed by current from overhead conductors is by no means as remote as it would appear to be. Requiring no outlay whatever for track construction and repairs, rights of way, etc., a system of electric trolley carriages might in many instances be found profitable where a railroad would not pay. It might appear as a begging of the question to put forward the trolley carriage in a discussion of self-propelling vehicles, but we mention it merely to show that the methods at disposal for electrically driven vehicles are by no means confined to the storage battery, while naturally the energy supply of all other types of carriages is limited to their fuel carrying capacity.

All indications point to a rapidly growing interest in vehicles of this class, an interest which is stimulated by the announcement of two new competitions,—that organized by the *Times-Herald*, of Chicago, with \$5,000 in prizes, and the other by the London *Engineer*, which holds forth incentives in the shape of prizes aggregating one thousand guineas. These competitions will enable American and English inventors to test their vehicles of this class and will afford a useful means of comparison with those of French design.

SPIDERWEB RAILROADING.

WHATEVER may be the motive power in the future of long distance travel, it is certain that suburban and interurban work has already fallen into the hands of the electrical engineer. There is no longer any conjecture about this matter, nor any serious argument. It has ceased to be a question of change and has become simply a question of the manner in which the change will be effected, or of the time it may require to take place. The change is not to be delayed because Col. Hain of the New York Elevated pretends to doubt the ability of electricity to handle his traffic, and it is not less certain because the New York Central even in these days of extreme heat suffocates its passengers with steam, sulphur and soot in its Harlem tunnel. Neither a company nor an individual can now stem the current, but they who are in power can do much to give it proper direction. It would be more frank on Col. Hain's part to admit that the cable roads are depriving the elevated roads of much of their traffic and that he has, hence, less money and credit available for the introduction of the new motive power and the abandonment of the old. Anybody who watches any day of the week the travel on the Third Avenue cables or that on Columbus Avenue with its crowded transfers to the conduit electric road on Lenox Avenue has no trouble in determining what is the matter with the Elevated. The inability of electricity to handle large travel on an elevated structure, even if it were a true plea, has nothing to do with the case; and, moreover, we all know that it is not true.

But turning to suburban traffic, we find the change in full operation. It is reported from Boston that the success of the Nantasket Beach road has already set the town talking and that the travelers on many other short branches centering there are anxious to know how soon they can enjoy electric travel with its many incidental advantages. This week the Burlington & Mt. Holly branch of the Pennsylvania road is to be put on full running schedule, and several other branches are now named as ripe for change. From Chicago comes the news not only that the Chicago & Northern Pacific is to convert its local lines but that the Illinois Central is already obtaining bids and estimates for such work. Last week saw the displacement, it is reported, of the last steam dummy in local travel at Kansas City. These are all very significant indications, and lose none of their importance because of their remoteness from slow and timid New York.

Looking yet further afield, it is evident that a transformation is in full progress in "interurban," as distinguished from "through" travel. The *Street Railway Review* has just made a compilation of all such projects, a large number of which are already begun, and shows them to number 190 with a total of 3,457 miles, located in no fewer than 31 states. The longest is 100 miles—Bellefontaine to Lima, O.—and there are several above 40 miles. These roads appear to us to group into three classes. The first comprises roads that take the place of steam roads that would have been built sooner or later. The second, includes roads that parallel steam roads and compete on superior terms for their traffic. The third class, chiefly of short roads, embraces a large number of little links between adjoining cities near enough to make light travel pay, but not offering in any case sufficient return had the old ponderous steam methods been adhered to.

It is above all curious to note how these roads reticulate the country, constituting as well by their number as by their lightness of construction, a veritable spiderweb of tracks. Ohio for example, has no fewer than 31 of them and little Massachusetts has 14. They are not necessarily straight, but bend and curve and fetch in a most delightful manner, the object of a great many being to pick up all the way travel possible. The maps of some that have been produced in our columns exhibit them as preferring the highway very decidedly to direct cuts across pasture and furrow; and when they reach a town they go into its heart instead of locating a station one mile out. There can be no doubt at all that they are going to develop a habit of travel among large masses of people hitherto untouched by the restlessness of the times; and it is equally obvious that they must shift no few centres of local trade and distribution.

Another element that strikes one in this interurban work, although it is not shown in the figures of the *Review*, is that a large mileage counts upon the utilization of water-power. Whether in the long run there will be enough of this to affect the extent of coal mining is not quite clear, but it will surely give a value to many natural powers now running to waste. The brilliant success of such work is seen at Niagara where a plant taking two or three thousand horse-power from the Canadian side of the Horseshoe operates admirably a standard road 13 miles long, double track; but in some instances there will probably be disappointment as to the amount of power available and the cost of utilizing it. The likelihood is that we shall soon witness a widespread adoption, in this branch of electric railway work, of the modern phase methods of transmission with rotary transformers. This has already been tried successfully in New England, and has even been adopted for the new trolley system in Dublin, Ireland. It would appear that with high voltage phase transmission, and rotary transformers judiciously placed, some notable economies will soon be recorded in interurban electric railway work, both on roads using coal in the power-house and on those using water or natural gas.

MEETING OF THE NORTHWESTERN ELECTRICAL ASSOCIATION.

The third convention of the Northwestern Electrical Association was called to order at the Leland House, Chicago, on Wednesday, July 17, by Vice-President George Grimm. In his opening address he spoke feelingly of the great loss which the Association had sustained in the death of their late President, Henry C. Thorn, and paid a glowing tribute to the ability and high character of the departed.

The speaker dwelt at length on the constant war waged against companies operating under public franchises. Inquiring into the causes which have dulled the sense of justice in the people Mr. Grimm said: In our case the cause should not be hard to find. How many corporations who are enjoying valuable franchises granted to them as gifts by municipalities conduct their business with any other thought or object in view than the profits to be made. They will improve the service or extend their lines if they must, or if they will gain additional patronage; but every move is actuated either by expected gain or public (municipal) compulsion. Complaints of poor service, irregularity, overcharge, and the like, are utterly ignored until recognition is compelled by public sentiment or authority. Competition is kept out, destroyed, or made harmless by combinations. Every effort is directed to the earning capacity, frequently for the purpose of forcing, by its dividend qualities, a stock, originally watered, up to par. Every concession requested by the community that gave it the possibility of existence is resisted until the patience of the public is exhausted and sentiment becomes inimical to an industry that should have received united support and commendation. This sentiment of dislike, and clamor for municipal ownership of the quasi-public industries like electric lighting, gas works, waterworks, and the like, is the natural outgrowth of either unduly large profits extorted by the line of policy above referred to, or by lack on part of the managers of proper regard for the rights of the people. I fail to find any other cause. The root of it all is that some of these corporations seem unable to realize that their business is not strictly private but semi-public in its character, and should be managed accordingly. While undoubtedly most of these industries are run upon a broad gauge plan, regardful and mindful of the rights and wishes of the public, yet it must be evident to all that there are many that are liable to every charge of the evils complained of. The public never stops to discriminate in passing judgment, and the result is that the general sentiment becomes hostile to all alike and ready to accept any plan of relief or retaliation which may be suggested even as against industries which are not at fault and which would innocently suffer. Thus the agitator and pot-house politician find ready soil to receive their seeds of communistic doctrine and willing ear for the abuse of others and self-glorification

The following are now the officers of the Association:—President, George Grimm. First Vice-President, Pliny Norcross. Second Vice-president, P. H. Korst. Secretary, William Goltz. Treasurer, John Schuette.

The following members, associate members and friends were in attendance A. V. Abbott, M. B. Austin, C. O. Baker, F. N. Boyer, Lewis Brittan, A. C. Bunce, Loren W. Burth, Chas. G. Burton, G. L. Cole, Carroll Collins, L. H. Cooke, F. A. Copeland, Crouse-Tremaine Co., George Cutter, Fred De Land, F. E. Donohue, George A. Farwell, W. J. Ferris, Channing S. Gage, William Goltz, C. E. Gregory, George Grimm, T. F. Grover, G. Gunderson, Eugene Hall, J. H. Harding, E. M. Highlands, M. Hussey, W. D. Jameson, P. H. Korst, R. F. Kountz, H. D. Latimer, S. P. Lord, W. W. Low, A. G. Luthy, G A. McKinlock, George S. McLaren, John C. McMynn, John R. Markle, Chas. S. Marshall, F. McMaster, E. P. Maxwell, T. R. Mercein, S. F. B. Morse, G. M. Newton, Pliny Norcross, Robert W. Ney, F. Overbagh, C. C. Paige, J. S. Paulson, O. M. Rau, W. C. Remington, John Schuette, J. Stedman, J. S. Stephens, M. L. Stevenson, B. S. Terry, W. H. Thorp, W. H. Upham, John Valentine, M. A. Warren, John B. Whalen, M. C. Wheaton, George Whyte, Theo. Wilberling, J. F. Wiley, C. D. Wilkinson, R. A. Wilson, W. Wilson, James Wolff, H. O. Woodruff.

At the conclusion of the president's address, the following papers were read and discussed: "Central Station Economies," by J. S. Stephens; "Electrical Interference," by A. V. Abbott.

In the afternoon a number of the visitors took the Metropolitan Elevated Railway and inspected the power house and repair shops of that road. On the return trip they visited the Chicago Edison Co.'s new Harrison Street Station where Mr. Louis A. Ferguson, electrical engineer of the Company, showed them the many features of interest to be seen in that magnificent plant.

On Thursday the meeting opened with a paper by W. D. Jameson on "Boiler Feedwaters; their Treatment," followed by a paper by George Cutter on "Electric Street Lighting."

At two o'clock a goodly contingent left by special train on the Santa Fé R. R. to visit the works of the Drainage Canal, and during the trip Messrs. Morse and Wolff of "Kerite" and "Grimshaw" fame, most hospitably regaled the hot and thirsty travelers with Milwaukee's very best brew. Messrs. Chas. E. Gregory, A. C. Bunce, and Chas. Valentine the other members of the entertainment committee were the right men in the right place and were untiring in their efforts to give their guests a good time and succeeded admirably.

In the evening, a party visited the Columbia Theatre to witness the performance of the "Merry World," and during the progress of the play the names of many well known members of the fraternity were frequently mentioned.

On Friday morning the following papers were read: "The Choice of Transformers," "The Advantage to be derived by testing every Transformer before placing it on the line," by Prof. D. C. Jackson. "Boilers and Practical Specifications for the Building of Same," by J. C McMynn.

In the afternoon a very enjoyable coaching trip was made to Jackson Park, and on the way the party stopped at "Ye Inn," where Mr. S. F. B. Morse most hospitably entertained all those who were fortunate enough to be on the excursion. On the return journey Mr. Geo. C. Bailey invited the party to stop off at the Hyde Park Club, where he generously attended to their inner wants, after which the party drove back to the city.

EXHIBITS.

The General Electric Co. exhibited their arc lamps, incandescent lamps, watt meters, switches, and other station supplies.

The Western Electric Co. had a variety of arc lamps and auxiliary apparatus on exhibition.

The Columbia Incandescent Lamp Co. had a very nice line of their well-known lamps exhibited, which were in charge of Mr. Jos. M. Hill, their Chicago representative, who had also on show one of the Wagner Electric Co.'s transformers.

C. E. Woodruff Co. showed flexible conduit manufactured by the American Circular Loom Co., also wire and other supplies.

L. B. Allen exhibited his well-known soldering stick, which was also to be seen in most of the other supply exhibits.

The Mason Electric Co. had a line of the Fiberite Co.'s specialties, also lightning arresters, oil filters, etc.

The Buckeye Engine Co., Salem, O., showed a fine model of one of their class "B," medium speed, simple horizontal engines, which had the top of the cylinder off so as to show the working of the slide valve and cut-off.

The Hart & Hegeman Mfg. Co.'s interests were looked after by their wideawake representative, Mr. Geo. S. Searing, who had on show a new adjustable incandescent light balance, manufactured by Gillespie & Taett, Edwardsville, Ills.

The Sioux City Electrical Supply Co. showed some overhead railway supplies and electrical specialties.

The Electric Appliance Co. had a very nice exhibit of Paranite cocktails and Packard punch, and as usual did a roaring trade. Mr. Chas. Wells waited upon the customers in his usual pleasant style.

The Fort Wayne Electric Corporation had an interesting exhibit of a liquid description to which there were many visitors, upon whom it had an electrical, but by no means a shocking effect.

The Hayes Fyfe Co, Chicago, had two of their automatic motor starting rheostats on view, which were regarded with great interest by the many visitors to their exhibit.

The Osburn Electric Supply Co had a very neat exhibit of electrical specialties.

The Dearborn Drug & Chemical Co., Chicago, were in evidence with their well-known vegetable boiler compound, and showed some samples of what bad water can do in the way of producing some very tough-looking specimens of incrustation that were taken from steam boilers. They presented all visitors with one of their very neat leather bill cases, which were highly appreciated by the recipients.

S. F. B. Morse & Co. had a very neatly printed round cardboard souvenir, with a picture of the genial head of the firm in the centre, and "Day's Kerite," in prominent letters, all round the edge.

The Sunbeam Lamp Co. were represented by Messrs. F. S. Terry and A. S. Terry, who were very busy amongst their numerous friends in the interests of their well-known lamps.

Chas. E. Gregory was around, brisk as a bee, and at the same time had a sharp eye to business.

The Roberts Electric Co. showed one of Mr. H. J. Roberts' new patent wood boring machines, which does good and quick work.

E. Nashold was present looking after business for the Nashold Cleat Co.

CENTRAL STATION ECONOMICS.[1]

BY J. S. STEPHENS.

The author believed that the location of an electric light or power plant has as much to do with its success as almost any other factor and hence strongly urged the necessity of employing a reliable and experienced electrical engineer to decide on the location of the plant. The buildings should be substantial and

1. Abstract of a paper read before the Northwestern Electrical Association, Chicago, July 17-19, 1895.

laid out with a view to certain increase. Care should be taken in the selection of apparatus and not too much confidence should be placed in the usual guarantees of efficiency. When the station is in operation a thorough system of keeping books and records will serve to indicate in what direction economies are possible in the future.

ELECTRICAL INTERFERENCE.[1]

BY A. V. ABBOTT, C. E.

THE author discussed the subject of interference of circuits carrying different currents and divided these disturbances into the following classes: 1. Leakage. 2. Inductive disturbances—(*a*) electro-magnetic, (*b*) electrostatic. 3. Common path interference. 4. Electrolytic action.

To avoid the first, leakage, good construction and insulation of the circuits was indispensable.

Inductive disturbances of an electro-magnetic nature could be avoided by so locating the disturbing conductors with relation to each other as to neutralize the induced currents, such as by transposition either of the disturbing or the disturbed circuit. A remedy might also be found under certain conditions by opening the disturbed circuit either by a condenser or by the introduction of an impedance of such dimensions that it will choke out the objectionable impulses, while permitting the desirable ones to pass.

Electrostatic induction is hardly likely to play any important part except in telephonic installations. It is the most difficult form of induction to cure, as neither impedance coils or condensers have a marked effect as a remedy. The method of transposition is also comparatively inoperative, the only radical cure, apparently, being the removal of the interfering circuits to a considerable distance from each other.

The remedy for disturbances due to "common path returns," such as the earth, are complete metallic circuits; in the case of electric railways much could be done to avoid these difficulties by proper bonding of the rails.

Regarding the avoidance of electrolytic action the author advocated the employment of the double-trolley system in railway work.

BOILERS AND SUGGESTIONS FOR BOILER SPECIFICATIONS.[2]

BY J. C. MCMYNN.

The author began by giving actual examples showing how the cost of steam consumption in several plants was materially reduced by the introduction of improved apparatus. He then gave a brief account of the material requisite in boiler construction, and followed this by a specification of a steel tubular boiler.

BOILER FEED WATERS: THEIR TREATMENT.[3]

BY W. D. JAMESON.

THE author enumerated the various impurities met with in boiler feed waters, such as the salts of lime, magnesia, potassium, iron, silica and aluminum, combined with carbonates, hydrochloric and sulphuric acids. The only substances which can be successfully used in the boiler to break up and convert sulphate of lime into a form in which it can be readily washed out, are sugars properly blended, which, when used under the high heat and the existing conditions of the steam boiler, convert this sulphate of lime into a complex mixture of saccharates and carbonate of lime, and this in the presence of the tannin matters, is partially converted into tannates of lime.

Of all the deleterious actions which take place in steam boilers electrolysis or galvanic action is the easiest to handle, for one simply needs to satisfy the water with some vegetable starch and saccharine matter, and in that way break up the conductivity between the negative and positive poles, whether they be brass connections (negative) and the boiler plate and flues (positive) or the iron of the boiler plate.

Scaling ingredients are converted from crystallizable scale forming carbonates and sulphates having a great affinity for hot metal, into non-crystallizable tannates and saccharates of lime and magnesia, being a complex mixture of these with some carbonate, the sodium salts being readily handled in the same manner. This complex mixture of the saccharates, carbonates and partially converted tannates, is of an inert nature, having the physical properties of a soft oozy mud of the same specific gravity as the water, and no affinity for hot metals; neither has it the clay-like properties but will readily wash out with the water when cleaning the boiler.

The author also gave his experience in the avoidance of other deleterious actions in boilers, and concluded by showing the destroying action of oil in boilers which forms heavy compounds with the salts in the water, and settling at the bottom causes overheating and dropping down of the sheets and the buckling of tubes. Oil could best be handled by means of tannin extracts.

SOCIETY AND CLUB NOTES.

MASSACHUSETTS ELECTRIC LIGHTING ASSOCIATION.

The Massachusetts Electric Lighting Association visited Nantasket Beach, Boston, on July 18, to the number of 85 for the annual meeting. The trip down was made by steamer, and as the guests of the New York, New Haven & Hartford Railroad Company, the members made a tour of the Nantasket Beach electric branch on a special train and inspected the power house. Upon their return from this trip the party took carriages to the Atlantic House, where a banquet was enjoyed.

At its business meeting, the association elected these officers: President, F. A. Gilbert, Boston Electric Lighting Company; vice-president, Hon. Theodore C. Bates, Worcester Electric Lighting Company; executive committee, C. L. Edgar of Boston, H. S. Cogswell of Fitchburg, C. C. Frye of Lynn, F. S. Richardson of North Adams and F. S. Almy of Salem.

PERSONAL.

DR. NIKOLA TESLA has had the Order of the Eagle conferred upon him by the Prince of Montenegro. He has already received the Order of St. Sava from the King of Servia.

STANDARD ELECTRIC CO.

Probably no exhibit at the Northwestern Electrical Convention attracted more attention than the new arc lamp recently placed on the market by the Standard Electric Company of Chicago, and of which more than a thousand are now in use. In exterior appearance it is similar to the former type of Standard lamp, but when the cover is lowered, the marked simplicity of the mechanism is apparent. As this lamp is a prime favorite with Mr. Perry, it was perfectly natural that he should find pleasure in debating on its good qualities; how the potential of the arc remained just the same regardless of the position of the clutch, the lamp magnets always being in perfect electrical balance; how an instantaneous and silent arc was always assured; how the arrangement of the magnets does away with the necessity of perfect cleanliness to insure economical and satisfactory service. It is claimed that the potential of the arc never rises above 50 volts or drops below 46, and though the amperes should vary from five to fifteen, still the arc will form silently and instantaneously at the normal voltage and so remain. As the contact points in the automatic cut-out are of platinum there is no corrosion and the lamp cuts out without a spark. For conducting the current to the carbon rod there is a substantial brush capable of carrying more than 20 amperes. The brush is so arranged that the friction upon the rod is reduced to a minimum. For outdoor service each lamp is provided with a double pole weatherproof switch which is enclosed in a compact "detachable cap" and is so constructed as to permit the lamp being instantly removed from the line without opening or breaking the circuit.

COLUMBIA INCANDESCENT LAMP CO.

Mr. J. H. Rhotehamel, president of the Columbia Incandescent Lamp Co., of St. Louis, writes hopefully with regard to the lamp situation, and reports business as being equal to that of former years, and in fact much better than it has averaged of late. Columbia lamps are good and must always be in demand. Mr. Rhotehamel believes that the public is rapidly educating itself on the lamp question and knows a good thing in lamps when it sees that same. The Columbia Company has been a leader in this educational work, and Mr. Rhotehamel says that its efforts are being steadily rewarded by a substantial increase in business. Columbia goods are becoming extensively known and used, and deserve the appreciation they enjoy.

A WOMAN TO BE GERRYCIDED.

MARIA BARBERI, an Italian girl who killed her blackguard lover with a razor, has been condemned to death by electricity. If she is executed, she will be the first criminal disposed of in this way

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 16, 1895.

Alarms and Signals:—

Automatic Railway Signal, A. J. Griffin, Wilkes-Barre, Pa., 542,638. Filed Aug. 7, 1894.

Electric Annunciator, H. C. Thomson, Boston, Mass., 542,664. Filed Oct. 2, 1894.

Cable Railway, W. M. Wood & J. C. Miller, Elmira, N. Y., 542,670. Filed May 29, 1894.

Device for giving an alarm at the power house in case of accident.

Burglar Alarm Circuit Closer, A. A. Vanderpool, Newark, N. J., 542,697. Filed Nov. 8, 1894.

An improved form of window spring.

Railway Signal, F. B. Wetherbee, Walpole, Mass., 542,699. Filed May 3, 1895.

Electric Block-Signal for Railroads, A. C. Gordon, Rochester, N. Y., 542,761. Filed May 18, 1895.

Electric Signal Apparatus, T. B. Keeler, Rahway, N. J., 542,769. Filed Mch. 11, 1895.

Relates to the so-called "electric slot mechanism" signal.

Fire Alarm, J. R. McCoy, Marshalltown, Iowa, 542,775. Filed April 8, 1895.

The alarm circuit is controlled by a thin thread placed on the walls and ceilings of the apartment, and which is readily destroyed by the heat.

Fire Alarm Device, J. F. Snapp, Frichton, Ind., 542,788. Filed April 18, 1895.

A thermostat in which the fusible material is a bar of celluloid.

Annunciator, J. W. Olson, Chicago, Ill., 542,883. Filed Nov. 21, 1894.

Details of construction.

Electrical System for Signalling Between Trains, A. Basanta y Baqua, Madrid Spain, 542,916. Filed Jan. 21, 1895.

Conductors are placed parallel with the track and contact made by arms carried on the cars.

Electric Annunciator, W. J. Clarke, Trenton, Can., 542,926. Filed Feb. 5, 1895.

Eleven connecting wires are required for the first ten rooms, after which only one additional wire is required for every ten rooms up to one hundred rooms, and after that only one additional wire for every one hundred rooms.

Signaling Apparatus, L. S. Crandall, Parish, N. Y., 542,928. Filed Feb. 17, 1893.

A compound monogram studded with lamps which are lit by a combination switch in the form of a key board.

Distribution:—

Means for Generating Electricity from Car-Wheel Axles, M. Moskowitz, Newark, N. J., 542,771. Filed Feb. 27, 1895.

Details relating to car lighting from a dynamo driven by the car axle.

House Wiring Fixture, C. F. Case, Akron, Ohio, 542,994. Filed April 20, 1895.

A combination insulating tube for gas pipes and electrical conductors.

Regulator for Alternating Electric Currents, C. P. Steinmetz, Schenectady, N. Y., 542,968. Filed Feb. 16, 1895.

A primary or inducing member having an exciting winding coupled in shunt across the circuit to be regulated and a secondary member having a corresponding winding in series with one of the circuit mains. The two members of the regulator are adjustable.

System of Electrical Distribution, G. W. von Siemens, Berlin, Germany, 542,979. Filed April 26, 1893.

A four wire system with automatic regulating devices for maintaining constant potential by counter-electromotive force of said devices.

Dynamos and Motors:—

Regulation of Continuous Current Motors, M. J. Wightman, Scranton, Pa., 542,667. Filed April 2, 1895.

Permutes the number of poles, so that the motor is changed from a two-pole to a four-pole motor or vice versa—to obtain variations of speed and torque.

Galvanic Batteries:—

Elements of Galvanic Batteries, F. A. Von Alimonda & N. Von Alimonda, Castello Alimonda, Near Sagrado, Austria-Hungary, 542,953. Filed Oct. 30, 1894.

A hook shaped connection is embedded in the carbon electrode.

Lamps and Appurtenances:—

Carbon for Electric Lamps, H. F. Cabirau, Paris, France, 542,695. Filed Apl. 11, 1895.

Consists of two pencils nested together, the inner pencil being provided with a central opening and radial channels or air passages between the nested pencils.

Electric Arc Lamp, E. Thomson, Swampscott, Mass. & C. E. Hartman, Lynn, Mass., 542,662. Filed June 25, 1894.

The control of the feeding is directly dependent upon the action of the controlling magnet irrespective of its adjustment for the arc length.

Measurement:—

Electric Measuring Instrument, E. Thomson, Swampscott, Mass., 542,663. Filed Apl. 25, 1895.

Details of construction relating to alternating current voltmeters or ammeters.

Electric Meter, H. A. Rowland, Baltimore, Md., 542,945. Filed Apl. 19, 1895.

Consists in supporting the coils of the meter by the same non-magnetic conductor which produces the damping effect by its revolution in the magnetic field.

Miscellaneous:—

Electric Governor, W. W. Handy, Lake Roland, Md., 542,640. Filed May 1, 1895.

Designed especially for governing water wheels.

Stop Cock Lock, C. Heyman, New York, 542,642. Filed March 20, 1895.

An alarm is given when faucets have b en carelessly left open.

Stop Cock Lock, C. Heyman, New York, 542,643. Filed April 23, 1895.

Similar to the above.

Insulating Shield for Metallic Poles, W. J. Braley, Fall River, Mass., 542,675. Filed April 17, 1895.

Sub-Marine Mine, W. H. Huskisson, London, Eng., 542,732. Filed Nov. 22, 1894.

A Hughes induction balance contained in the mine has currents induced in it on the approach of a ship, which currents act to close the circuit that explodes the mine.

Apparatus for Automatically Displaying Advertisements, C. K. Marr, London, Eng., 542,802. Filed Sept. 18, 1894.

Time-Recorder for Water-Gauges, E. P. Wells, Highlands, Colo., and E. R. Hubbard, Walden, Colo., 542,910. Filed Feb. 25, 1895.

Separating Metals from Foreign Substances, H. H. Whitacre & A. C. Wolfe, Wellsville, O., 542,911. Filed Feb. 14, 1895.

Coils surrounding the pipe extract from any liquid or viscid matter all steel or iron particles or filings which may be held in suspension.

Electric Gas-Lighter, H. G. Grier, Philadelphia, Pa., 542,959. Filed May 31, 1895.

An automatic electric gas-lighter particularly adapted for "Welsbach" burners and which may be carried wholly by the shade-holder and can be made detachable.

Railways and Appliances:

Running Gear for Electric Railways, B. J. Arnold, Chicago, Ill., 542,617. Filed April 13, 1891.

An improved method of motor suspension.

Switches, Cut-Outs, etc.:—

Fuse Holder, L. C. Orrell, Bellevue, Ky., 542,713. Filed Oct 22, 1894.

Make and Break Switch, M. Moskowitz, Newark, N. J., 542,772. Filed April 23, 1895.

Details of construction.

Polarized Compound Switch, M. Moskowitz, Newark, N. J., 542,773. Filed May 2, 1895.

Pole changer to be used in connection with dynamos, subject to armature reversal.

Electric Switch, G. T. Eyanson, Philadelphia, Pa., 542,848. Filed May 10, 1895.

Relates to a knife snap switch.

Telephone Relay or Repeater, C. H. Arnold, Boston, Mass., 542,618. Filed March 16, 1895.

Embodies a double bridge between the conductors of the main line and two local repeating circuits controlled by the two receiving magnets, with induction coils having two secondary windings one-half on either side of the bridge, and their primaries in the local circuit.

Telephonic Repeating Circuit and Apparatus, C. H. Arnold, Boston, Mass., 542,619. Filed March 16, 1895.

Modification of the above. A condenser is interposed in the bridge whereby it is divided conductively, but left inductively continuous.

Telephone Relay Apparatus, W. L. Richards, Malden, Mass., 542,657. Filed March 16, 1895.

Embodies artificial balancing circuits of suitable resistance and capacity, one for each main circuit.

Telephone Repeating Circuit and Appliance, W. L. Richards, Malden, Mass., 542,658. Filed March 16, 1895.

Embodies a polarized switch in connection with the relay magnet.

Telephones:—

Coin Controlled Telephone, C. B. Hopkins & T. H. Elson, Spokane, Wash., 542,679. Filed March 16, 1894.

Microphone, H. Carbonelle, Brussels, Belgium, 542,892. Filed Oct. 9, 1894.

The microphone button is free at one end, while the other is rigidly connected with the vibrating plate by means of a hollow elastic tube which is smaller and shorter than the former.

Telephonic Relay or Repeating System, C. H. Arnold, Boston, Mass., 542,918. Filed March 16, 1895.

For description see page 93, this issue.

REPORTS OF COMPANIES.

PERKINS ELECTRIC SWITCH CO.

The Perkins Electric Switch Company of Hartford has increased its capital, says the Hartford, Conn., *Courant*, from $50,000 to $125,000, by adding 750 shares at $100 each, all paid in. The new stock has been subscribed for by the following: C. G. Perkins, 400 shares; Roland Mather, 150; Edward W. Hooker, 50; J. M. Allen, 25; James Nichols, 25; E. C. Frisbie, 50; P. H. Woodward, 20, and Talcott Brothers, Talcottville, 80 shares.

THE GENERAL ELECTRIC-WESTINGHOUSE "DEAL."

The *News Bureau* of Boston in a long article on the failure of the negotiations for an understanding and agreement between the Westinghouse and General Electric Companies says:—

The report that negotiations had been renewed about four weeks ago was practically acknowledged, but later it was reported that Mr. Coffin was working upon a plan which he would soon offer to the Westinghouse Co. for final acceptance or rejection.

The most interesting feature of the story is the explanation of why these negotiations failed. It seems that it was due to the action of members of a couple of banking houses having close relations on important matters. Report now has it that there were frequent conferences with the result that it was decided as a first step to negotiations on a new basis, that the Twombly plan was to be brought to a head by the discharge of the General Electric committee, which was done, and the public informed by an official statement to the press.

It is said that the bankers then felt that matters would thereafter be in their hands and all General Electric parties evidently were told to "keep hands off" for a channel had been opened that might lead to better terms for General Electric than contemplated by the abandoned plan.

As a result of a lot of work, a plan, probably the one proposed to be presented by Mr. Coffin, was evolved and offered, but it being one-sided it met with no response except a complete cessation of negotiations between bankers.

We have reason to believe that a majority of both boards favor some arrangement concerning patents but that it is likely that nothing will be heard on the subject until the difficulties which have arisen by the negotiations last referred to have been removed.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE SOLAR ELECTRIC COMPANY IN ITS NEW QUARTERS.

ONE of the most important of the changes and consolidations of recent years is that which has now gone into effect merging the separate organizations and business interests of the Brooklyn Electric Manufacturing Co. and the Solar Arc Lamp Co., and making what is undoubtedly a strong new element in the field of electrical industries related to light and power. The new corporation is called the Solar Electric Co. and its personnel includes a number of capitalists and public men, among whom may be mentioned Hewitt Boice, popularly known as the "Blue Stone King," president of the Catskill Railroad and the Kingston, N. Y., National Bank; Andrew Baird, the stone merchant of Brooklyn who was a favorite candidate for the mayoralty of that city last election; Senator Jacob Rice, and Mr. Samuel O'Connor, who has done so large an amount of conduit building. Associated prominently in the new company with these gentlemen are Mr. George A. Mullen, who becomes secretary and treasurer, and Mr. St. Louis Wintner, general manager; Messrs. Boice and Baird being respectively president and vice-president.

The company have given up their works in Brooklyn and have concentrated the offices and factory in the new, fireproof and power Vernon Building, 65 and 67 Duane street, which runs through to 593 and 595 Pearl street. In this way they not only have an opportunity to watch and expedite all work going on, but can consult directly with customers over the work that may be under contract. This factory floor, 175 feet by 60, is supplemented by two large galleries in which smaller detail work is done. Here the company is now busily engaged in the manufacture of a large number of Solar arc lamps, for which several orders are on hand, and in the construction of various switchboards. Within the present year the Brooklyn Electric Manufacturing Co. had already made between 60 and 70 boards, and the record for the year under the new régime is expected to eclipse any made before. One of the boards just finished is intended for the palatial residence of Mr. George Vanderbilt, at Biltmore, N. C., where it will be in operation this winter.

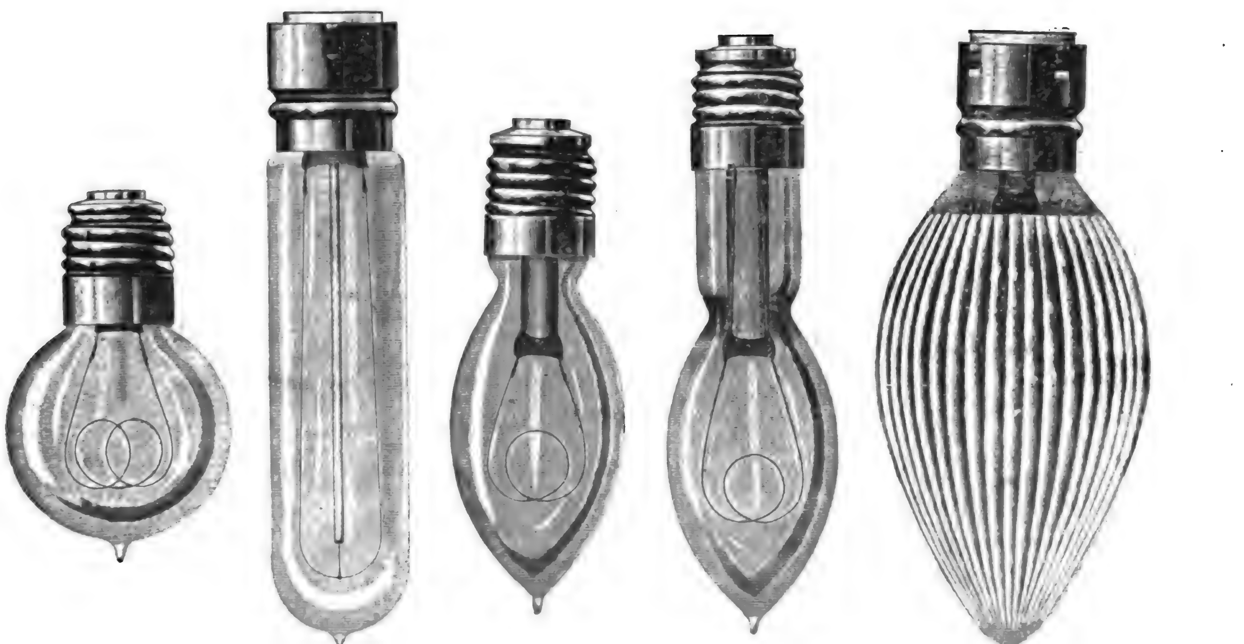
In THE ELECTRICAL ENGINEER of May 29, 1895, Mr. Joseph Sachs gave an excellent illustrated description of the Solar arc lamps, which are based upon the escapement and rack principle, and on the methods adopted for their construction. It will have been noted from that article that the lamp is simple in design and calculated to do good service. Besides switch boards and arc lamps, however, the company make a variety of switches, their specialty being the quick-break; and they are well equipped with tools and machinery for a wide range of first class work. Mr. Wintner gives the business close personal attention, and Mr. Mullen brings to bear on it a ripe experience including that gained with the Morrison Southern Electric Co.; the Brooklyn Electric Manufacturing Co. and other active enterprises.

OHIO BRASS COMPANY.

THE Ohio Brass Company have published a comprehensive catalogue, in which their electric railway supplies, including construction material, line devices and car appliances, are clearly and fully illustrated. They have established a special line of pole tops, arms, and brackets, which are of the best malleable iron, giving the necessary strength for supporting the heavy feeder lines, and the strain of the span and guard wires, with a minimum weight of metal. Their pole brackets, hangers, and general trolley fittings are carefully made, and their supply list includes electric headlights, light fittings, and every requisite for train lighting.

NEW BUCKEYE ORNAMENTAL LAMPS.

ALWAYS on the alert to furnish new designs and improved quality in lamps, the Buckeye Electric Co. are now placing on the market a number of interesting types of ornamental lamps, some of which are illustrated in the accompanying engravings. Fig. 1. shows the "Imperial" lamp made in voltages from 48 to 130 and from 8 to 16 C. P. It is furnished both frosted and plain and dipped blue-green, ruby and amber. Fig. 3 shows the short "candle-flame" lamp, adapted for low voltages and 10 C. P. Fig. 4 is the long "candle-flame" lamp, of the same voltage and C. P. as the short lamp. Fig. 5 shows the "pine apple" type, made for 48 to 130 volts and 8 to 16 C. P.



FIGS. 1, 2, 3, 4 AND 5.—NEW BUCKEYE LAMPS.

We also illustrate the Buckeye "bung-hole" lamp in Fig. 2, which is specially adapted for use in breweries and distilleries for the examination of casks.

VENTILATION IN THE NEW BOSTON PUBLIC LIBRARY.

In our description of the lighting plant in the New Public Library at Boston we were in error in stating that the ventilation was accomplished by a Davidson fan. It should have been stated that the ventilating fan was specially designed by Mr. Frederick Tudor, engineer, and built by Mr. D. P. Gosline of 30 Oliver St., Boston. It is a centrifugal fan with 8 main blades which receive the air from an expanding cone. As the velocity of the air increases, the blade area is increased by supplementary blades of shorter length, thus ensuring a positive delivery of all the air. It is run and controlled at variable speeds by means of a rheostat which is connected with the electric motor.

THE UNION ELECTRIC CO., Manchester, N. H., are making some important additions to their plant. An order was given by them a few days ago for a 500 H. P. vertical cross compound condensing engine to the Ball Engine Co., Erie, Pa.

THE METROPOLITAN ELECTRIC CO.

Any of the many friends or customers of the Metropolitan Electric Co. Chicago, who may visit their fine store on Fifth avenue about this time will find in the activity and bustle to be seen there, that they are among the exceptions to the slackness of trade that is usual at this time of the year.

This is as we all know the season when the fan motor is a boon and blessing to all mankind, and the Metropolitan Electric Co. carry a large stock of fans in all sizes suitable for the office, dwelling or store; for the latter and particularly for restaurants the celebrated Dayton ceiling fan motor cannot be surpassed. It is ornamental in design and handsomely finished and adds greatly to the appearance of any room in which it may be placed. This Company also bought the entire stock of the well known Ries and Scott alternating fan motors, as that Company have retired from business. These fans have a handsome appearance combined with low cost and high efficiency, and intending fan purchasers would do well to send in their orders promptly as the stock is limited and with the present demand must soon be all sold out. The Victor direct current desk fan also combines the above mentioned qualities and is in great demand.

The celebrated P. and B. products for which the Metropolitan Electric Co. are the Western Agents are so well established, and their reputation is so great all over the world, that they need very little comment, and it suffices to say that the Standard Paint Co. are largely increasing their business the older they grow.

The "Mac" Tape which is manufactured by the Metropolitan Electric Co. is first class and is in active demand. The demand also still continues for the Metropolitan incandescent lamps. The Metropolitan Co. have recently placed a large number of the Gilliland telephones of which they are the owners, and when the existing uncertainties of the telephone business are a thing of the past there is every reason to predict that the Gilliland phones will come well to the front.

The attention of the street railway companies of the country may be called to the portable hose bridges which the Metropolitan Company manufacture, and which are being largely used in Detroit and other cities, and have in all cases given the most perfect satisfaction. This invention has been noticed in many of the daily papers all over the country. This device comprises great usefulness combined with simplicity. It can be firmly attached to the rails in a few moments, and in case of fire the hose can be run across the rails and the bridge put in place, so that the traffic will be uninterrupted.

The Metropolitan carry a large stock of wire, lamp cord, lamps, switches, batteries, bells, annunciators, construction tools, push buttons, buzzers, electric gas lighting supplies and all of the many other electrical specialties which are too numerous to mention in these columns.

Their new Catalogue which is now in the printer's hands and will be ready early next month will contain some 600 pages, and will be handsomely bound, and profusely illustrated. The Company have had a very laborious task in its compilement, but they will be well paid for their hard work, as it will be a necessity in every place of business connected with the electrical and street railway fields. Those who are interested in the above lines are requested to send in their orders for copies.

NEW YORK NOTES.

THE ELECTRIC MAINTENANCE CO., of No. 50 Broadway, have appointed The E. G. Bernard Co. of Troy, N. Y., their agents for eastern and central New York, and are about to open a branch office at Philadelphia.

GLEN COVE, N. Y.—The new plant of the Franklin Illuminating Co. has started up. It has a General Electric incandescent dynamo of 1,000 lights, a Ball & Wood engine of 100 H. P. and a Hogan vertical water tube boiler. An arc machine is to be added as soon as possible.

LAWRENCE ELECTRIC CO.—An execution for $6,483 has been received by the Sheriff against the Lawrence Electric Company of 130 Pearl street, New York City, in favor of William Lawrence. The Company was sued in October, 1894, by Hicks Brothers. Mr. Lawrence purchased the claim, and he said the company agreed to pay him, but has not done so. F. H. Mollenhauer has obtained a judgment for $1,041 against the company.

MR. WM. H. PIKE, JR., so long connected with the Brady Manufacturing Company, of Brooklyn, N. Y., and who has been their Superintendent for two years, has resigned, and is now taking a much needed rest. Mr. Oluf Tyberg, M. E., so long and favorably known as a practical and theoretical engineer, and as the designer of many labor saving machines automatic and otherwise, has recently acquired an interest in the Company and accepted the position of superintendent of the factory of that concern at 68 Washington street, Brooklyn, N. Y., where he will be pleased to serve his friends and patrons.

WESTERN NOTES.

THE PARTRIDGE CARBON CO., of Sandusky, O., report an excellent business in their electric railway carbon specialties. They expect soon to be selling to at least 75 per cent. of all the roads in the country, as they are always adding new customers to the old.

MR. H. M. BRINKERHOFF, electrical engineer for the West Side Construction Co., Chicago (known as the Metropolitan Elevated Ry. Co.), has awarded the contract for furnishing a telephone system to the Western Telephone Construction Co., Chicago. This system contemplates about thirty telephone outfits, one at each station, so that communication may be had from point to point.

THE GARDNER ELEVATOR CO. of Detroit, Mich., have received from Donaldson & Meir, architects for Traugott, Schmidt & Sons' eight story building, a contract for three direct electric elevators, two passenger and one freight. Perret motors, Elektron controlling devices and steel construction will be used. This is the third large contract for electric elevators awarded the Gardner Co. in the last two months.

THE ELECTRIC APPLIANCE Company are exhibiting a beautiful line of fancy styles of their Upton Arc lamp which they are now prepared to supply for direct and alternating constant potential circuits, and also for regular series arc work. The fancy lamps are beauties, and everything considered are not expensive. The regular standard Upton lamp is a very business like affair, and on this the Appliance Company claim to be making prices that are decidedly interesting. They have a large stock in Chicago ready for prompt shipments. The Electric Appliance Co. find trade remarkably good and promising to be even better.

CENTRAL ELECTRIC CO.—Although the Central Electric Company have been in the railway business, to fill all kinds of railway orders, but a few months, it is astonishing the number of contracts that have been procured and the promptness with which their orders have been filled. Their overhead material is considered by railway people to be up to date in every respect, and many railway companies are adopting it as their standard. The Billings & Spencer drop-forged overhead material, and thousands of drop-forged commutator bars are being sold. The Central Electric Company carry all of these specialties in stock, and are prepared to make very prompt shipments. They are keeping right up to the times, and are obtaining many new devices of merit that they may supply to their constantly increasing trade the latest, most satisfactory and best of everything required.

NEW ENGLAND NOTES.

BERGER & ROGERS, successors to Berger, Rogers & Potter, engineers and contractors, have removed their office from 620 Exchange Building, Boston, to 255-7 Broadway, Troy, N. Y., where they will attend to electrical work in all its branches.

MR. GEORGE C. EWING has resigned his position as superintendent of the Composite Brake Shoe Co. and has opened an office at 620 Atlantic Avenue, Boston, where he is now handling a line of high grade supplies as the New England agent for a number of prominent houses.

THE W. S. HILL ELECTRIC CO., of Boston, have made an assignment to Mr. Ferdinand A. Wyman, of Boston and Hyde Park. No definite future action has as yet been arranged, but it is the intention of the assignee to carry on the manufacture of the Hill goods for the present, and to endeavor to place the company in a better financial condition than ever before. The Hill Co. have a lot of important work on hand at present in the way of switchboards and switches, amongst which is a large order for the Congressional Library of Washington, D. C., and this will be carried to completion just as usual.

PHILADELPHIA NOTES.

MESSRS. J. W. PARKER & CO., the enterprising agents of the Ball Engine Co., of Erie, Pa., have just delivered to the Camden, (N. J.) Horse R. R. Co., a 400 H. P. Ball vertical cross-compound engine. This is the second engine of this type sold to the company through Messrs. Parker & Co.

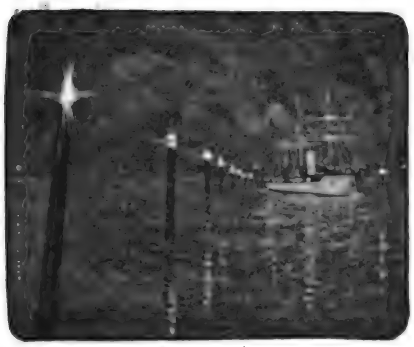
THE MERCANTILE TRADE LIST SUPPLY CO., 601 Times Building, Pittsburgh, Pa., makes a specialty of furnishing lists of names and addresses of persons engaged in any trade, profession or special line of work. These lists are incessantly revised, and embrace practically the whole field of industrial pursuits. The company also undertakes to address envelopes, wrappers, &c., and aims to do all its work in a thorough and satisfactory manner. It is noteworthy that these lists are not printed but furnished in manuscript form only.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

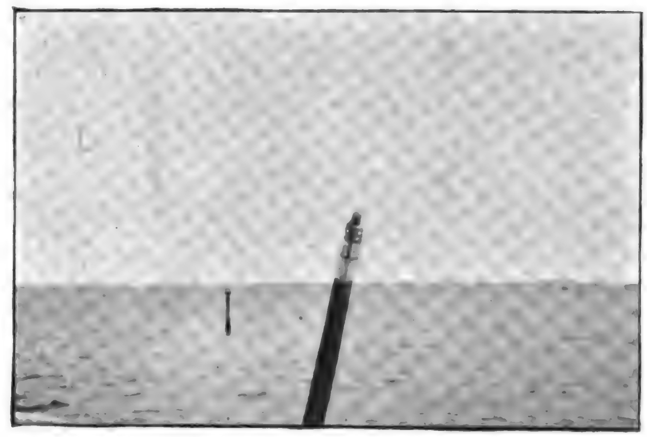
Vol. XX. JULY 31, 1895. No. 378.

THE USE OF THE ALTERNATING CURRENT FOR LIGHTING GEDNEY'S CHANNEL, NEW YORK HARBOR.



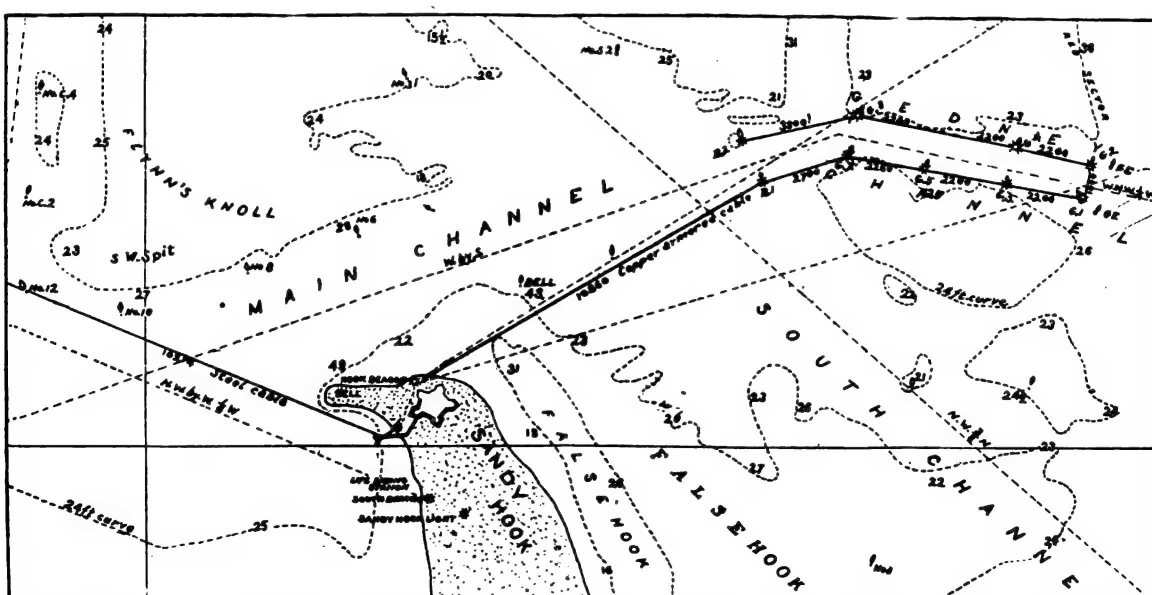
"Coming Up The Lane."

It will be remembered that some years ago, the U. S. Lighthouse Board undertook to light Gedney's Channel, New York Harbor, by means of a series of buoys lighted by electric current from a plant on shore. The work was fully described in the electrical and daily journals at the time, and being so novel, naturally attracted a great deal of attention. The "lane" marks the entrance from the Atlantic Ocean to the Bay within Sandy Hook, and is known as the Gedney Channel and the Southwest Spit. The experimental plant with direct current proved so satisfactory that it has been recently enlarged, the desire of the board being to still further increase the safety of the port. The lighting station is situated almost at the extremity of Sandy Hook. To the equipment formerly used to illuminate the experimental buoys, two 9 K. W. General Electric, multipolar, four pole, alternators have been added. These are arranged with commutator and collecting rings to allow of the delivery of both alternating and continuous current. The alternating apparatus supplies the current for the buoys of the Gedney Channel circuit and the lamp in the Hook beacon ; the continuous current lights the buoy in the Southwest Spit. The alternating



THE NEW ELECTRIC BUOYS, GEDNEY'S CHANNEL.

current employed has a frequency of forty cycles per second, the generator making 1,200 R. P. M. These machines are of the latest type, the fields being of cast steel and the drum armatures being provided with removable coils.



MAP OF GEDNEY'S CHANNEL AND SOUTHWEST SPIT AS LIGHTED BY ELECTRIC BUOYS.

The primary voltage of the Gedney Channel circuit is 1,000 volts, alternating current. At the lamps this voltage can be reduced to 100 volts. The direct current for the operation of the Southwest Spit circuit is 150 volts. Of the two generators mentioned, one is used as a reserve and

each is provided with a 12 kilowatt transformer filled with oil. The switchboard is of white marble arranged for the alternating and direct currents with indicating and controlling devices for their operation; all machinery being in duplicate.

From the dynamo station at Sandy Hook two underground line wires are laid to the landing place of the Gedney cable at the north end of the Hook, and branch wires are laid from it to the lamp in the Hook beacon. Two other wires are laid from the landing place of the cable leading to the Southwest Spit electric buoy. In both these circuits one of the wires is lead covered, with rubber insulation, the other wire is bare. They are laid underground in a substantial boxing of creosoted wood.

ADJUSTING THE BUOY LIGHTS.

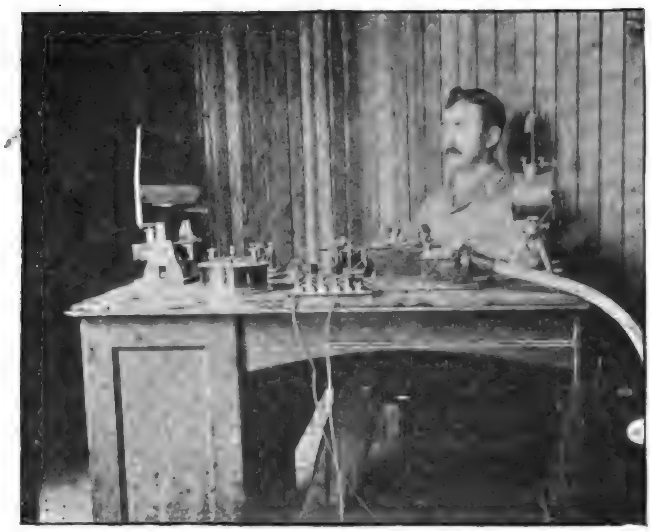
After leaving the land near the Hook Beacon, the cable of the Gedney Channel proceeds as follows:

	Feet.
Hook Beacon to Buoy "B 1"	10,860
Buoy "B 1" to Buoy "G 7"	2,700
Buoy "G 7" to Buoy "G 5"	2,200
Buoy "G 5" to Buoy "G 3"	2,200
Buoy "G 3" to Buoy "G 1"	2,200
Buoy "G 1" to Buoy "G 2"	1,000
Buoy "G 2" to Buoy "G 4"	2,200
Buoy "G 4" to Buoy "G 6"	2,200
Buoy "G 6" to Buoy "G 8"	2,200
Buoy "G 8" to Buoy "B 2"	3,300
Actual cable on Buoys at 100 feet	600
	32,660
	6.18 statute miles.

The length of the subaqueous Bishop cable in use on the Southwest Spit circuit is 10,214 feet; it consists of one conductor of 7 wires of No. 18 B. & S. stranded copper and two armors of steel wire; its weight per statute mile is about 19,113 lbs. The Bishop cable of the Gedney Channel is of the single conductor single armored type; the conductor consisting of 7 No. 18 B. & S. stranded copper wires, the armor of No. 18 B. & S. hard drawn copper wires. The insulation is well seasoned gutta percha and has a resistance of not less than 300 megohms per statute mile. The exterior diameter of this cable is about $\frac{3}{4}$ inch, that of the direct current cable, $1\frac{1}{8}$ inches.

The transformation of the alternating current from 1,000 volts in the primary to 100 volts at the lamp is effected by a small transformer of 600 watts capacity, fitted right inside the head of the wooden buoy. These transformers are mounted in strong watertight cases with heavy oil as an additional insulation, and are mounted inside the buoy without impairing the strength of the head. Of course all openings into the transformers are made securely water tight.

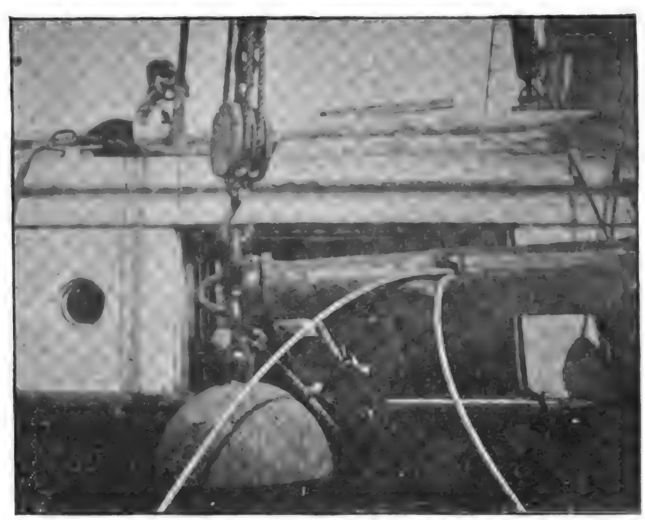
The lamps which are set at the top of each buoy



TESTING THE BUOY LIGHTING CIRCUIT.

—which is a stout pole about 70 feet long anchored by a heavy "mushroom" weight—are covered by a bell glass globe and they are of 100 candle power. The lamp is 5″ in diameter and the filament is spiral. Each lamp takes from $3\frac{1}{2}$ to 4 amperes of current. A lamp of similar size and candle power illuminates the Hook beacon and is so fitted in the lens that it can be removed at any time and another substituted in case of accident. The glass is extremely thick and tough.

Small transformers are used in connection with the



LOWERING SUBMERGED END OF BUOY AND MUSHROOM ANCHOR.

Hook light, similar in character to those used in the wooden buoys. In addition to lighting the channel and the beacon, the current from the alternating generator is also used to furnish light for the keeper's dwelling and the station lamps.

The cable for this work was manufactured by the Bishop Gutta-Percha Company, of New York, and the electrical installation was effected by the General Electric Company, which company furnished the entire electrical apparatus. All the buoys with their attachments, sinkers, lanterns, and lantern guards were supplied by the Government.

The cables were laid by the steamer "Western Union" of the Western Union Telegraph Co., accompanied by the

light house tenders of the Inspector of the third district which laid the buoys and made the connections. After the completion of the work, a certain time had to elapse during which the plant was on probation. The entire plant has now been accepted by the Light House authorities and its acceptance marks the completion of one of the most important works which the Light House Board has undertaken within recent years.

THE BURRY STOCK AND NEWS PRINTING TELEGRAPH.

Although the newer and later applications of electricity to light and power have absorbed the attention of electrical workers it must not be supposed that the older fields are by any means neglected. Indeed the comparative freedom from competition has induced more than one inventor to return to those older fields. Telegraph printers have always had a fascination for telegraphic inventors, and more inventions have been made of late in this branch of the art than perhaps in any other. Our readers will, we know, be interested in the most recent advance in such apparatus, which has gone into practical application, displacing earlier types. Heretofore, "tickers" have as a rule been driven by weights or springs, which have had to be wound by hand from time to time, an expensive and bothersome matter, as the tickers are widely scattered through a city. Attempts, it is true, have been made to wind these springs or weights automatically, but these have met with indifferent success. Electro-motors with reciprocating armatures have been proposed and perhaps used in experimental work. Notwithstanding all this, weights have continued in use as the motive power of the tickers. As is well known, a ticker includes quick-acting escapement-operating electro-magnets, and sluggish "printing" electro-magnets, and it has been proposed to use the latter

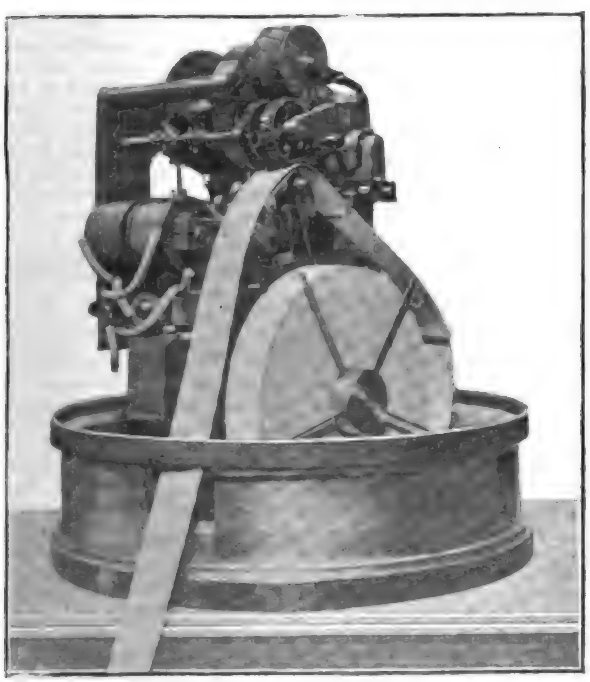


FIG. 1.—THE BURRY SELF-WINDING STOCK PRINTER.

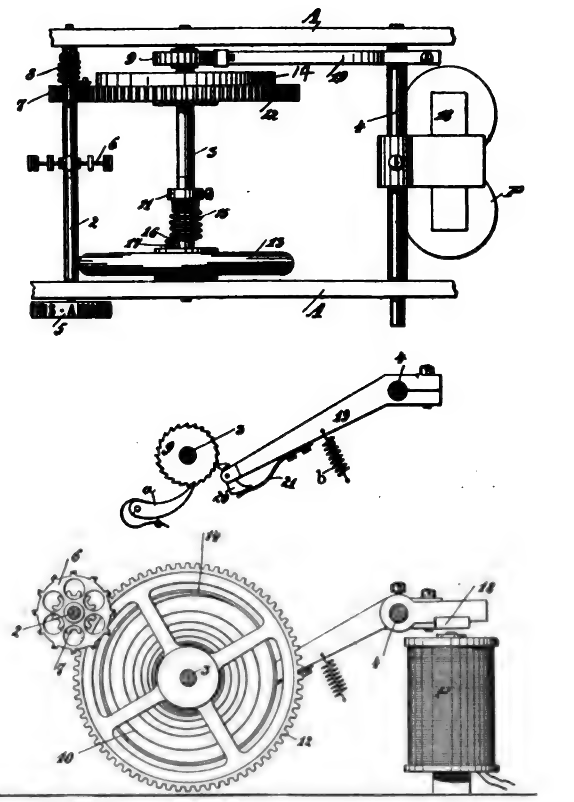
to wind the main spring driving the mechanism of the ticker; but as the time-intervals between "printing impulses" are subject to great variations in practice, it sometimes happens that the main-spring may run down or it may be overwound. Also, difficulties have been encountered in the gearing between the weights and the escapement controlling the type-wheel of the ticker.

After long experiments, Mr. John Burry, electrician of the Stock Quotation Telegraph Co., of New York, has succeeded in completely overcoming all these difficulties and in using the current which operates the printing magnets for winding the mainspring of the ticker, and this without any increase in the strength of the current.

The new printer is shown in perspective in Fig. 1 and



FIGS. 2 AND 3.—THE BURRY SELF-WINDING STOCK PRINTER.

Figs. 2 and 3 show the old square or box-like ticker, as changed by the introduction of the invention in place of the weights and clockwork heretofore employed. In Fig. 2, 3 indicates a shaft to which one end of the mainspring is fast, the spring being within the drum 14, which itself is loose upon the shaft. The spring is not fast to the drum, however, but its outer convolution bears frictionally against it. The numeral 9 indicates a ratchet fast on the shaft 3, the shaft being operated by the pawl-carrying lever 19, which is operated by the "printing magnets" P. The drum 14 is fast to the loose gear wheel 12, which latter meshes with a similar wheel 7, loose on the shaft 2 which carries the type-wheel 5 and escapement wheel 6; spring 8, fast at one end to shaft 2 and at the other to the wheel 7, forms the connection between the wheel and shaft, and avoids the jar and other annoyances heretofore experienced in this part of the mechanism of the ticker.

The principal feature of the printer consists in the fly-wheel 13, loosely mounted upon the shaft 3, and connected therewith by means of the spring 15, fast at one end to the shaft and at the other end to a pin 16 in the hub of the fly-wheel. A stop pin 17 projects from shaft 3 into the path of the pin 16 and acts as a stop.

Whenever a prolonged or "printing" impulse is sent over the line to the magnets P, the lever 19 is operated and quickly turns the ratchet wheel 9 one or two teeth; this winds spring 15 slightly (the inertia of wheel 13 preventing that wheel from moving at once) and moves the pin 17 away from pin 16; spring 15 soon puts wheel 13 in motion and the pin 16 striking against pin 17 of the shaft 3, gives the shaft an additional rotating motion from the energy of the fly-wheel. This latter motion of

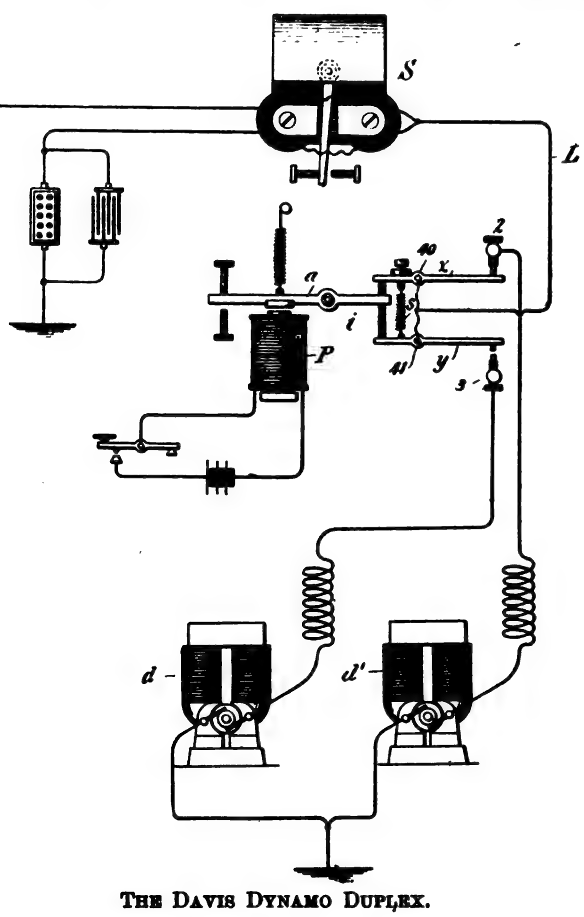
the shaft 3 is generally greater than that communicated to it by the lever 19, and, of course, the winding of the mainspring is also greater in like proportion. The machine is so set that the average tendency is to the overwinding of the mainspring and whenever this occurs the spring simply slips in the box 14. In case the mainspring slips, spring 8 drives the type-wheel. It will be noticed that the remodelled ticker contains comparatively few parts for driving the type-wheel.

It may be added that some 900 of the box-like tickers in New York City have been changed from weights to the above described method of driving them; also over 100 machines of the new model shown in Fig 1 have been built, and a large number are in course of construction.

THE DAVIS DYNAMO DUPLEX AND DIPLEX TELEGRAPH.

In a patent just issued to Mr. Minor M. Davis, assistant electrical engineer of the Postal Telegraph-Cable Co., that gentleman describes a pole changer, for duplex and diplex telegraph circuits, that is particularly useful where dynamo currents are employed. The objects sought were to produce a pole changer that would give clear sound, have elastic contacts, be easy to adjust and clean, be economical of power and be free from troublesome sparking while making rapid changes of polarity.

The accompanying diagram shows the pole changer and



The Davis Dynamo Duplex.

its application to a polar duplex. In the figure, P is a pole-changing transmitter. There are two movable contacts consisting of two unequally pivoted levers x and y, pivoted at 40 and 41, respectively, the location of the fulcrum or pivot being about two-thirds the length of the lever from the fixed electrical contacts 2 and 3. The operating or actuating lever a mechanically connects with the shorter arms of the levers through the medium of the rod of insulating material i. It will be noticed that the length of i is such that when x contacts with 2 and y is separated from 3, the mechanical connecting piece i is slightly separated from x, and vice versa. The two levers x and y are spring retracted, the retracting force being applied to the shorter arms; one spring s is employed with a proper adjusting device to draw the shorter ends of the two levers toward each other. The two levers are shown electrically united, forming the movable terminal of the line, while the fixed contacts 2 and 3 form, respectively, the terminals of two dynamos d and d' of opposite polarity.

LITERATURE.

Die Sekundär-Elemente. Part I. By Dr. Paul Schoop Halle a, S, 1895: Wilhelm Knapp. 210 pp. 5 ½ x 8 ½. Paper.

There are a number of works on storage batteries which give a very fair idea of the state of the art, considered from the standpoint of the construction of the cells, rather than that of the chemical operations which proceed during charge and discharge. Information relating to the latter is scattered through a large number of periodicals, but it would take more time than the average man has at his disposal to gather from this mass what is really useful, and in many cases his inexperience would lead him to the adoption of methods of work, which have not resulted satisfactorily in practice. Dr. Schoop has undertaken the task of collecting what is of value in the domain both of the manufacture of the storage battery and its chemistry and has succeeded most admirably in his undertaking.

The volume before us is devoted to the theory of the lead accumulator and the construction of the Planté cell. A short historical introduction is followed by the theory of the lead accumulator, and the consideration of various stages of oxidation which the lead undergoes in the electrolyte. Special attention is also devoted to what is frequently neglected in storage battery work, namely, the electrolyte. Dr. Schoop devotes two chapters to this important detail, treating of the effects of temperature, electric conductivity, the formation of persulphuric acid, etc. The manufacture of lead accumulators of the Planté type, follows this section, containing a most searching investigation into the action of this type of accumulator, including the various effects noted during the operation of the cell. Among the cells particularly described are those of Pollak, the Oerlikon, the Cheswright. The book closes with a chapter on the employment of Planté storage batteries in central station work. The book is excellently printed and the text is elucidated with accurate drawings and diagrams. The wide experience of the author in this particular field will, through these pages, prove of great value to all engaged in storage battery work, particularly that with the Planté type, which seems to be gradually increasing in popularity, more especially abroad.

WHAT IS SAID OF "THE ELECTRICAL ENGINEER" DATA SHEETS.

Our esteemed contemporary, The Electrical Engineer, deserves our congratulations and best wishes for success with its new departure in the form of Data sheets which appear as a supplement to the paper. Since it takes an enormous amount of time to prepare a note book of your own, and since it is very difficult, at least in a great many cases, to determine under what heading to put a certain statement, table or the like, very few people can afford the time to collect such data as they would like or perhaps almost of necessity must remember. The Electrical Engineer has engaged Mr. Albert B. Herrick to publish data sheets of such size as to make it convenient to carry them in the coat pocket. These sheets are indexed by numbers very closely to the Dewey system of library indexing which is probably the best in the country. In that way a man is saved the trouble of searching where to place a certain notice and also saved the trouble of remembering facts. Professor Helmholtz in a memorable lecture delivered before the University of Heidelberg, stated that he considered those men the most educated who knew where to find things, a statement which he repeated before the students of Columbia College on his visit in 1893. By helping the readers of the paper to "know where to find things," The Electrical Engineer takes the place of an educator, the highest ideal to which journalism can aim. In an editorial the editors say: "The management of the Engineer will greatly appreciate the help of its friends in this novel work, which it believes likely to be of great value and importance to all branches of the profession." We think that this statement might even be turned around, for the readers would be very grateful if The Electrical Engineer will index for them data which they would like to preserve.—*Electric Power.*

ELECTRIC STREET LIGHTING.[1]

BY GEORGE CUTTER.

In considering a question like that of lighting streets, alleys, and public squares, we should first define the results to be produced by the lighting system. It appears to me quite simple to define the theoretically perfect lighting, but it is not as easy to decide which system gives results nearest to the theoretical; local conditions affect this question more or less. A general uniform illumination of mild intensity, such as that of a dark cloudy day or possibly that of a clear night with a full moon is the theoretical condition to be produced by artificial lighting. This is especially the case after bedtime.

There is an illumination better than either of these two for our study to reproduce artificially, and that is a clear night in winter in extreme northern latitudes. That is, the midnight light of the land a little south of the midnight sun. When we can produce this general uniform illumination of mild intensity most desirable in a town gone to sleep we will then have the best night illumination. And the rivalry which has led to the use of brilliant effects with really poor practical illumination will be replaced by attempts to produce the best approach to this theoretical condition, and the glare which blinds a man for half a block with accompanying inability to see for the next half block will become obsolete.

But this mild illumination while it may be best for the outlying or residence districts during all hours of the night, is not sufficient for the business centre during the earlier hours of the evening. So for proper results we must produce a brilliant illumination of this business centre until bedtime, and for the sake of economy we must then change the down town illumination to the same mild intensity that serves for the residence districts earlier in the evening.

There is one important factor in street lighting which might modify our practice in regard to the best general illumination. It is the police duty of the light in preventing crime and in facilitating the capture of criminals. But even for this duty a uniform illumination of mild intensity is likely to prove best because the eye which is adjusted to a bright light cannot distinguish objects in a dull light.

There are various points to be considered when we come to the practical side of the question and try to determine what system will give the best approach to the theoretical results with the fewest practical objections. Among these points I might mention a few of the most important: 1. We should consider the means of distribution to produce the nearest to our theoretical conditions, that is, we should aim to procure a uniformity of light even of mild intensity in preference to a few extra bright spots with intervening dark spots. An exception can be made as before indicated for the business section before bedtime, a brilliant illumination of this section in the early part of the night changing to correspond with the rest of the city for the rest of the night. 2. Reliability of service of the lighting system, since it loses its effectiveness either as a safeguard as a path finder or unless it is perfectly reliable. 3. Steadiness of illumination is another point closely connected in importance to the one just mentioned, and in the same line of thought, viz., that of avoiding contrasts in illumination either in different localities or at different times.

Determining the last two points, brings us to the 4th, necessary skill of all labor and ease of procuring same, the employment of home talent to the greatest extent possible being usually advisable. If the installation and operation of our plant requires special skill, then absence of this skill might cause bad service or even total cessation of light.

Then there is the durability of the apparatus, together with ease and economy of replacing used up parts. In considering this we must look out for both the probability of permanency of the supply of duplicate parts, and the amount of attention to keep all in good working shape. After careful judging of the closely related points thus far enumerated we can well give attention to the 6th: Efficiency of conversion from coal pile to light. My only comment on this point is that I place it second in importance to that of general uniform illumination, as high efficiency can well be set aside for the other more desirable feature of uniformity. Considerations of this point of efficiency lead to the 7th, total operating expenses, the importance of which depends almost entirely upon local conditions, as also the 8th point, cost of necessary plant for producing the light.

This leads to the 9th: appearance of fixtures on streets and squares and on this point more attention should be given than is the usual practice. A large share of the opposition to overhead wiring would never have been raised if it had not been for the bungling work which is so common.

The Chicago & Northern Pacific R. R. has already begun work on the equipment of its Chicago suburban lines by electricity. It expects to have electrical trains running in about three months.

1. Abstract of a paper read before the Northwestern Electrical Association, Chicago, July 17-19, 1895.

PERSONAL.

HARRY BARRINGER COX.

Harry Barringer Cox.

Few advances have attracted so much attention of late as the work of Mr. H. B. Cox in the direct conversion of heat into electricity and in the improvement of thermopiles. As a matter of fact, Mr. Cox though coming forward at a single bound into widespread publicity is no novice, but has been a hard worker in electrical investigation for many years. He was born at Zanesville, O., in 1863, being a direct descendant of the Long Islander, Gen. James Cox, who was on Washington's staff, and a cousin of the late Hon. S. S. Cox, whose statue was recently set up in this city by the postmen as a tribute to his brilliant advocacy of their rights, in Congress. Young Cox was educated in the public schools of Cincinnati but when only 14 years of age struck out for himself by becoming a telegraph messenger in the P. C. and St. L. Railway office, where he at once learnt telegraphy and developed an insatiable interest in electricity. He continued in railway work, chiefly on the Cincinnati Southern until he was twenty-two, when he entered the service of the Cincinnati Electrical Co. as its electrician, a post for which close private study and attendance at the School of Design had abundantly fitted him. His first electrical invention was a railway train signal which was adopted on several lines but was at last superseded by the Westinghouse pneumatic whistle signal. He next invented the Gelatine Battery, which was the first semi-solid cell to be extensively used, and of which large numbers were made and sold. About this time he built a small private laboratory at Fernbank, O., a suburb of Cincinnati, and there began his investigations upon the direct conversion of heat into electricity.

Mr. Cox was called to Europe in the spring of 1888 by the German Government for some special work, and upon his return he settled in the East, devoting himself during the fall and winter to experiments on the New England coast, on sound, in relation to marine signaling. The results of this work were five papers read before the International Marine Conference at Washington. The Light House Board also published in its annual report a complete digest of Mr. Cox's work on this subject.

These experiments may, perhaps, be regarded in the light of a diversion, for they were no sooner closed than Mr. Cox at once resumed direct conversion work, his studies in which field have really been most exhaustive, altogether aside from active investigation in his laboratory at New Haven. He has a most complete library bearing on the subject, including not only every book but every patent; while the most voluminous record of all would probably be found to consist in his own researches which have been tireless and numberless. The first and only account that has been given to the public was prepared by Mr. Cox himself for The Electrical Engineer, and appeared in its issue of May 1, when the apparatus was very fully illustrated and described. Since that time Mr. Cox has had to go to Europe on business connected with his inventions, and in a recent letter from Paris he wrote to this journal: "The subject of the direct conversion of heat must interest the public for I have, as a result of my descriptive article in your paper, received over 900 letters of inquiry, many of them coming from the furthermost parts of the civilized world." Mr. Cox's work has, indeed, been of the kind to encourage new hope as to the early practical fruition of efforts in the domain of direct conversion; and every electrician entertains the wish that Mr. Cox may be successful in the important lines of work he has marked out and along which he has already gone so far.

The Walkill Valley Electric Light Co., of Walden, N. Y., intends to increase its plant by adding an incandescent light dynamo, an arc system, and a 100 H. P. engine. Address, A. J. Fowler.

ELECTRIC TRANSPORTATION DEPARTMENT.

A RIDE ON THE NANTASKET ELECTRIC RAILROAD.—A NEW ERA IN SUBURBAN TRANSPORTATION.

BY J. B. BAKER.

A ride on the railroad running from Pemberton to Nantasket and sharing with the Boston harbor steamboats the traffic to the latter popular beach resort, is a novel and exceedingly interesting experience, now that the road has been equipped for electric motive power. I got on one of the open cars the other night for the ride to Pemberton, one of a large crowd getting on at Nantasket, and occupying every available inch of space in the seats of the three or four cars making up the train. Many others, late comers, wished to stand on the top running board which lines the sides of the cars, but were peremptorily ordered off by the conductor.

The cars bear a resemblance to the "open" variety of street cars in respect of having seats running all the way across, and being quite open at the sides; but here the resemblance stops. For they are almost as long and fully as wide as "steam cars," and the three steps running along the whole length of the car bring the height of the passenger from the ground fully equal to that of the seat in an ordinary railroad train. The cars are well lighted, by incandescent lamps, of course, and are attached in a train of three or four to the locomotive. Here there is a distinct retrograde movement, in an artistic sense, I think, from the steam locomotive—at least the handsome American one, with its delicate and powerful mechanism in plain sight—resembling what might be called a cross between a "dummy engine" and a baggage car. Only the headlight, carried low in front like those on the street cars, and the trolley pole slanting up from the roof, showed it to be really the locomotive of a true "broomstick train"—the very latest edition of the iron horse.

When all the passengers were seated, and the conductor had assured himself that no one was standing up outside, the "all aboard" signal was given, and we started up. And now one of the most striking differences between this train and one on a steam road was shown. Without an actual jerk enough to be disagreeable, yet the start was a remarkably quick one; the sensation imparted to the passenger as the motorman turned on "the juice" was one of great exhilaration at the quick attainment of speed. Moreover, one could feel an instantaneous and marked acceleration each time he turned through an additional notch in the controller. This was to some extent no doubt due to the lightness of the cars compared with steam cars of the same capacity; but principally to the more direct pull of the electrically driven locomotive over the necessarily jerky and irregular traction of the steam engine.

In a very few moments we were running along the shore at a rate of speed which it would be hard for any of our Boston suburban trains to equal. The reason why passengers are not allowed to stand outside now became apparent. With the trolley poles flashing by at the rate of 35 miles an hour or more one would need to have a cool head and a good firm hold to keep from being thrown off on going around some of the curves. As it was, one felt like holding on to something although securely seated; and the occasional greenish flashes from trolley wire or rails, with the clanging of the gong—for all the world like that on a patrol wagon in sound and look—helped to make the sensation an exciting one. Once in a while the whistle was blown—by compressed air—and its note was free from the hoarse, discordant quality of the steam whistle.

The trip to Pemberton includes numerous stops, which prevent any sustained high speed; yet no one who has ridden in this up-to-date train can fail to perceive that the electric locomotive gets its train up to speed quicker and apparently easier than a steam locomotive can. The stops, too, are made quicker, as the air brake which is used brings the light cars to a standstill with no jerk or grinding, yet very positively and quickly.

As a whole, the experience is a most enjoyable one, and the impression is gained that this experiment in suburban passenger traffic under extraordinarily severe conditions is to be a signal success, and is to mark the beginning of a new era in railroading.

TROLLEY COMPETITION WITH THE LONG ISLAND RAILROAD.

The active competition of the trolley road that runs from Long Island City to Flushing has caused the Long Island Railroad to announce a reduction of fares on their north shore division that runs to the same villages as the trolley. The reduction is the second since the trolley road was opened.

ADOPTION OF ELECTRICITY ON THE PENNSYLVANIA'S MT. HOLLY STEAM BRANCH ROAD.

With regard to the supercession of steam on the Mt. Holly-Burlington Branch of the Pennsylvania Railroad, the *Philadelphia Record* of July 28 has the following article descriptive of the inauguration of the electric trolley service furnished by the Westinghouse Electric Co. :—

The new trolley line of the Pennsylvania Railroad between Burlington and Mount Holly was formally opened to the public yesterday, and scored an instant success, not only in mechanical operation and speed, but also in the patronage it received and the reduction in fares made possible. As a steam road the line has never paid, and for this reason it was selected by the railroad company as a promising field for experiments as to the advisability of supplanting steam by electricity. If these prove as successful as expected, it is believed that the same change of motor power will be made on many other short branches of the "Pennsy."

Only one trolley car was run between Mount Holly and East Burlington yesterday, and upon nearly every trip it was well filled. It ran over the road very smoothly and rapidly, the schedule time between the two points being 20 minutes for the seven miles, a reduction of five minutes from the old steam schedule. With the introduction of the trolley the company increased the service between the two towns, and also reduced the fare—two moves that are highly appreciated by the people of that section. The new schedule calls for 10 trains each way weekdays, instead of six under the old schedule, and nine on Sundays, instead of one, as formerly. Under the present schedule one train each way is propelled by steam, and runs between Mt. Holly and Burlington. The other nine trips are by trolley, and the cars run only to East Burlington.

Even more interesting to the public than this increase in service is the radical reduction in passenger fares. The new rate, which is standard between Mount Holly and East Burlington and all intermediate points, is 10 cents. To Burlington the fare is 15 cents, as against the old rate of 10 cents and 18 cents to intermediate points, and 24 cents to Burlington. All single tickets east or west of Mount Holly and Burlington have been reduced 14 cents and excursion tickets, 20 cents.

A good idea of the popularity of the new road can be formed from the figures of the station agent at Mount Holly. Up to 5 o'clock yesterday, he reported the sale of 68 tickets, of which 11 were to Burlington and the other 57 to East Burlington and intermediate points. Besides the sale of these tickets the receipts by the conductor for duplex tickets up to the same hour were $10. These figures may seem small to the ordinary observer, but, compared with the passengers carried before the change went into effect, they represent an increase of fully 300 per cent.

The officials of the company at Mount Holly, who watched the operation of the new line very closely yesterday, expressed the belief that the rush of travel was not spasmodic and prompted only by curiosity, but that it had come to stay and would gradually increase. The reduced fares, they argued, would tempt people who heretofore have transacted their business between Mount Holly and Burlington by letter to use the trolley and transact it in person.

Already there are symptoms of trolleyosis in Mount Holly, and trolley parties are talked of. The Christian Endeavor Society of Mount Holly, will, it is understood, take the initiative and go to Burlington on Friday evening by trolley.

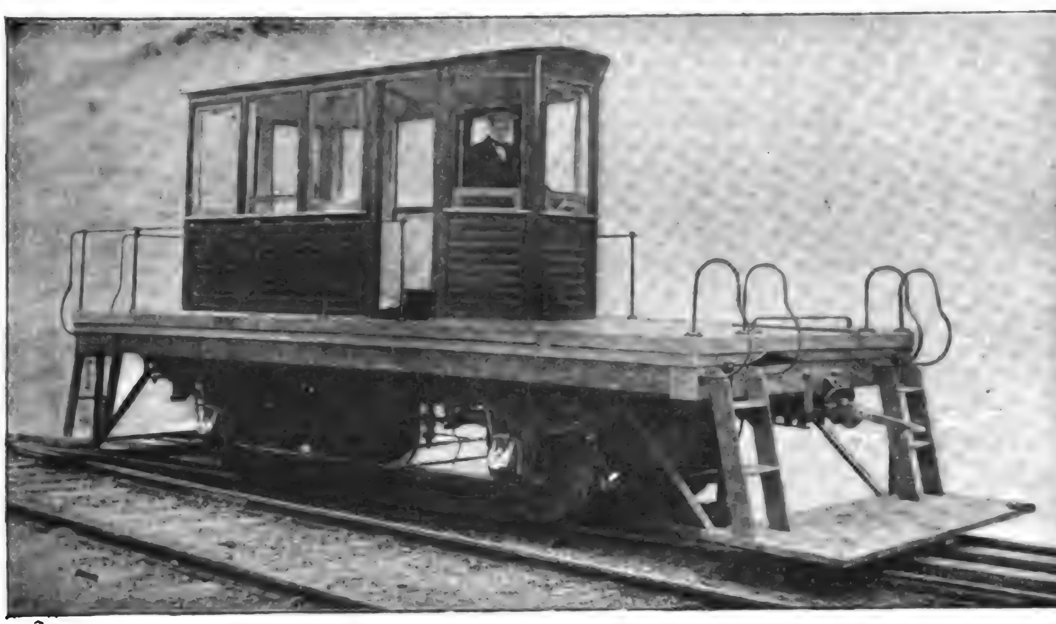
While Mount Holly and points along the road are enthusiastic over the advent of the trolley, the people of Burlinton don't join in the enthusiasm. Indeed, they are very much incensed at the action of the Pennsylvania Railroad in running trains through their city without stopping, a change which came with the advent of the trolley and reduced fares. When the company began to trolley the Burlington and Mount Holly branch it was the intention to build the line to the main station in Burlington. The authorities of that city, however, refused the application of the company to put down an additional track upon which to run their trolley cars, and they were then compelled to make East Burlington the terminus of the trolley line. As a retaliatory measure the company yesterday changed the schedule on its Amboy division so as to run all passenger express trains through Burlington without stopping. A stop is made, instead, at East Burlington, where passengers from the Burlington and Mount Holly branch will make connections for points on the Amboy division.

The electrical plant which operates the new trolley lines is located at Mt. Holly, a short distance below the station. The building is supplied with a 300 horse-power boiler and a 300 horse-power Westinghouse compound engine and generator.

WHELESS MOTOR CAR IN THE WESTINGHOUSE YARDS, EAST PITTSBURGH.

We have already illustrated at various times the Wheless electric railway system now owned by the Westinghouse Electric & Mfg. Co., in which current is taken up by means of pins and shoes in the roadbed, operated electro magnetically by the passage of the car.

A line on this system has been in use for some time at the yards of the Westinghouse Electric and Manufacturing Co., at East Pittsburgh. The accompanying engraving, from the *Railroad Gazette* shows one of the motor cars used on this line. It is used for switching loaded cars in and out of the buildings, it being undesirable to use steam locomotives, on account of smoke and cinders. The motor will haul several cars as easily as a steam switcher. It has two 50-H. P. motors, one on each axle, and the floor is covered with about 8 in. of cast iron to give the necessary adhesion. This system has also been installed upon a branch of the Eckington and Soldiers' Home Railroad, about one mile in length, situated upon North Capitol street, beyond New York avenue, Washington, D. C., the system, however, differing from that which we have just described, in that the boxes are placed between the rails, instead of to one side, and short sections of flat conductor are used, instead of the pins. This line has been in operation during the past winter, and traffic upon it was not interrupted at any time by snow or ice. The contact shoes, while not rigidly supported, are sufficiently stiff to scrape off any ice which may form upon the track terminals, and should contact not take place at any one pin, which, however, is not at all likely, the momentum of the car would carry it over to the next pair. This line costs about $35,000 per mile of double track.



WHELESS CAR IN THE WESTINGHOUSE FACTORY YARD.

THE RELATIVE ECONOMY OF ELECTRICITY AND CABLE.

In a recent interview on the use of the trolley in Chicago, Mr. M. K. Bowen, superintendent of the City Railway Co. of Chicago said: "Electricity is a complete success as a motive power for surface roads under certain conditions. There is no probability that the cable will ever be replaced with electric cars, at least so long as the electric system is anything like it is at present. When there is sufficient traffic to justify twelve cars to the mile of double track the cable becomes the cheapest form of traction per car mile run, and electricity cannot compete with it. On the other hand, when the traffic is not sufficient to justify more than four cars to the mile of double track, horses become the cheapest form of motive power. With traffic anywhere between these two extremes electricity is the most desirable. The space in a barn taken up by a street car is 300 square feet. The space occupied by horses to run that car is 800 square feet. The change to electricity gives the railroads two-thirds more barn room. The limit of the capacity of cable lines is reached when a rear train is compelled to stop for a train in front of it, when the first train stops to take on or let off passengers. We came just about up to that limit in 1893, when we ran trains with fifty seconds' headway. With Clark street equipped electrically, taking care of the traffic of the cross-town lines, the congestion on the cable roads will be greatly relieved and there will be no danger of reaching the limit of their capacity for some years to come." This dividing line between cable and electricity might possibly disappear, we think, with a conduit system. The relative economy, it will be remembered, was stated by Mr. McCulloch, of St. Louis, in the remark that when a road earns $50 a day per mile of single track, it is more economical to operate by electricity; but when the amount reaches $100 a day, the cable is cheaper.

ARRANGEMENTS FOR EXHIBITION AT THE MONTREAL MEETING.

The executive committee of the American Street Railway Association announce that the Victoria Rink in Montreal has been secured for the street railway exhibition to be held in connection with the convention beginning Oct. 15. It is near the Windsor Hotel, the headquarters of the association. Supply companies proposing to make exhibits are requested to apply to Stonewall Jackson, local secretary, 17 St. Sacrament street, Montreal, Quebec. The executive committee have made an arrangement with M. Davis, customs broker of Montreal, for a reduction in custom house charges on goods to be exhibited, as follows: Warehouse and bond entry, $1; export bond entry, $1; making and procuring consular certificates, $1. When goods to be returned are valued at $50 or more, a consular certificate which costs $2.50 must be procured, but this is unnecessary in the case of goods which are valued at less than $50. Shippers should mark goods with their own name, and "Care of M. Davis, Montreal, for exhibition purposes," prepaying the freight, and sending invoices marked "certified correct," and signed. On arrival, Mr. Davis will make warehouse bond entry, and have goods delivered at the Victoria Rink.

When the exhibition is over, the owners of the goods will have to re-pack them, using preferably the original cases. It is a distinct advantage to have them in the same cases, so that the marks may be identified. Consignors must pay all freight and cartage.

Space will be allotted on August 1 to all exhibitors whose applications have been filed with the secretary and accepted on or before that date. Applications for space received and accepted after August 1 will be allotted remaining space, if any, in the order of their acceptance. The space will be charged for at the rate of 15 cents a square foot, and no space less than 50 square feet will be rented, nor more than 1,000 square feet unless by special arrangement with the secretary.

CLEVELAND'S TROLLEY BILLBOARDS.

THE Cleveland street railway companies have gone into the advertising business in a novel way, by building billboard cars, constructed with the purpose of showing the greatest amount of poster space, and these are kept running over the various city streets. The citizens would prefer to have the companies put on more cars for carrying passengers instead of crowding the streets with the trolley billboards.

HARTFORD TO NEW BRITAIN, CONN.

The company which is to connect Hartford with New Britain by trolley is the Newington Tramway Company. F. G. Breed, the President, is also superintendent of the General Railway and Electric Company of New Britain. The road will be built under a charter granted in 1893, which would have expired on June 29. On June 28 the company was organized and accepted its charter. It is claimed that the new road will not parallel either the New York and New England or the Consolidated Road. It is expected to have the road built by next Spring.

REPORTS ABOUT THE CHICAGO AND ST. LOUIS ELECTRIC.

The Chicago & St. Louis Electric Railroad, which started with a big hurrah three years ago, has collapsed, says the New York *Morning Journal*. There is a "To Let" sign on the company's offices in the Women's Temple, Chicago, and sundry creditors are seeking for some one who will pay them. The only address of the defunct company is now care of the general delivery, St. Louis, Mo. Rose-colored were the opening prospects. An air line between Chicago and St. Louis, electric trains running 100 miles an hour, yearly earnings of $2,895,000, and a 29 per cent. dividend were, among other things, mentioned.

A LONG ROAD FOR RICHFIELD SPRINGS, N. Y.

The Little Falls and Richfield Springs Railway and the Richfield Springs and Schuyler Lake Railway, the former to operate an electric street road, 18 miles long, from Little Falls to Richfield Springs, and the latter one a mile long, from Richfield Springs to Schuyler Lake, in the town of Richfield, Otsego County, have been incorporated. The Little Falls and Richfield Springs Railway has a capital of $200,000, and the Richfield Springs and Schuyler Lake Railway a capital of $20,000. The Boards of Directors of the two companies are identical, comprising Caleb L. B. Tylee, Frank H. Viele, George E. Tylee, Edwin J. Carpenter, John L. Miller, and Thomas J. Mack of Corning; Theodore C. Bates and William H. Tylee of Worcester, Mass., and H. Arthur Sillsbee New Bedford, Mass.

THE PHILADELPHIA FENDER ORDINANCE DEFECTIVE.

City Magistrate Jermon, of Philadelphia, has decided that the trolley fender ordinance is defective; and hence the city loses all the multitudinous suits it has been piling up against the local street car companies for non-compliance with it.

NANTASKET BEACH TROLLEY VERY SATISFACTORY.

Judge John M. Hall, vice-president of the New York, New Haven & Hartford railroad company when asked last week if the Nantasket branch of the Old Colony line, the first established steam road in this country to be devoted to electricity in both its freight and passenger service, was running satisfactorily under the new arrangements, he answered: "Thus far the results have been very satisfactory. We are now awaiting statistics from the Nantasket branch which will determine with more accuracy whether the electrical equipment has proved the thorough success which has been claimed since the branch was started. One thing is certain that the trains have run well under excessive excursion demands and at a high rate of speed. It is safe to say that if the experiment of equipping the road proves entirely successful, other branches of the Consolidated Road will be changed from steam to electricity in a very short time."

CONSOLIDATING PHILADELPHIA ROADS.

The plan to unite the Philadelphia, People's and Electric Traction Companies was completed last week. The plan provides for the amalgamation of the People's and Electric Companies, the consolidated concern then to lease the Philadelphia Traction Co. at 4 p. c. on a par of $100, which is equivalent to an annual dividend of 8. p. c. on the company's capital stock. The new company will have a capital of $30,000,000, and the shares will have a par value of $50 each, making 600,000 shares. The shares will be held at the disposal of the different companies thus: Philadelphia, 310,000; People's 155,000; Electric, 135,000. J. L. Welsh, president of the People's Traction Co., and also one of the receivers of the Reading R. R., will be the president of the new company. The new concern will issue bonds to the extent of $15,000,000.

Long Island.—A trolley road is proposed for the eastern end of Long Island from Orient to Riverhead, and the consents of property holders are already being secured through all the towns en route.

ELECTRICAL PREPARATIONS FOR THE ATLANTA EXPOSITION.

In our last issue we gave a number of details with regard to the preparations being made by electrical concerns for the Atlanta Exposition; and showed also the exterior of the finished building. We are now able to publish a cut of the interior, from a photograph taken for us last week; from which it will be seen that the building is ready for the reception of exhibits. The General Electric Co. is already on the ground with a large shipment and is energetically getting ready. Applications for space in the Electricity Building are still being received. Assignments have been made in the last few days to the Clark Electric Specialty Manufacturing Company, of Minneapolis, Minn., and also to the Post-Glover Electric Company, of Cincinnati, Ohio. The former will exhibit push buttons, battery boxes, bell boxes, transmitter boxes,

Interior of Electricity Building, Atlanta Exposition.

electric mouldings, and all woodwork pertaining to electrical work.

The Post-Glover Electric Company will exhibit electric light and electric railway supplies and fixtures.

A very interesting part of the exhibit to be made by the Department of Household Economics of the Woman's Board, at the Cotton States and International Exposition, will be cooking by electricity. Electric stoves will be shown in operation, and the process fully explained.

The Safety Insulated Wire & Cable Co. of New York has received the order for the underground cables for the 125 arc lights.

Letters to the Editor.

PROF. GEORGE FORBES ON PROF. ROWLAND'S LETTER.

With regard to the letter of Prof. H. A. Rowland, published in The Electrical Engineer of July 3, Prof. George Forbes has given out the following reply:

The above letter requires refutation on two points—(1) that Prof. Rowland had anything to do with the plans adopted for Niagara, (2) that the extract from one of my confidential reports is the specification which I sent out to manufacturers to bid upon.

I.—Prof. Rowland's Claims.

1. The officials of the Niagara Company have informed me and others that he was employed only to get him to withdraw his opposition to alternating current. To do this they gave him one (and only one) of my reports to them which dealt with this point, and they got me and others to instruct him. At our first meeting he stated *ex cathedra* that the Tesla motor was of no use; but cross-examination proved that he did not understand the principle of its action Seven months of instruction reversed this decision.

2. So useless was his report to the company that it was not shown to me until I had completed all my plans and decided on the dynamo design.

3. His report did nothing except to recommend the dynamo proposed by a certain firm, to whom, at the same time, he was trying to sell some patents for transformers. This dynamo was totally unsuitable.

4. His pitiable lawsuit showed, by the evidence of the com-

pany's officials, that he had nothing to do with the plans for our work, and that the directors relied entirely upon the advice and inventive capacity of their electrical consulting engineer.

II.—My Specification for a Dynamo.

1. *The quotation in Prof. Rowland's letter is not the specification I sent to manufacturers.* This accounts for much of his misunderstanding. That specification filled twelve pages of printed foolscap, was accompanied by twelve sheets of drawings, and was never shown to Prof. Rowland. My paper in 1893 to the I. E. E. contains an abstract.

2. The report of thirty-six pages which he read says at the end that it is *not* a final report; but it is a very good general account of the plans we have adopted. It is absurd to say I opposed what we have done. As the consulting engineer, I originated it and carried it all through.

3. What he quotes as my specification was a suggestion I made when a separate fly-wheel was thought necessary, as this was the only type (like the Siemens or Ferranti) which could possibly bring the weight down to what we were absolutely limited to, and if it could be made strong enough it was the best type electrically. That suggestion of a specification was guarded by the prefatory words, "*if* a thoroughly good machine, electrically and mechanically, can be designed on these principles, it ought to comply with the following specification." From designs I worked at it seemed possible, but I was not over sanguine, and I had not then hit upon the novel design of alternator with external revolving field, which did away with the necessity for a fly-wheel, which completely solved the problem, of which I sent out specifications which I caused to be constructed, which was described and illustrated in my paper to the I. E. E., about which Mr. Knapp in the discussion said it was the best possible design for the purpose, and for which the Company formally thanked me in writing as having saved them from a most awkward dilemma. I could not, however, with this design use so low a frequency as I desired.

I could say a great deal more, but do not wish to take up more of your valuable space. I wish it to be known, however, that Prof. Rowland's misconceptions are largely due to the fact that we did not think it necessary or advisable to inform him of what we were doing.

George Forbes.

34 Great George Street, Westminster, 9th July, 1895.

MAGNETO-ELECTRIC SPEED RECORDERS.

In reading an account of the machinery on that magnificent American liner "St. Louis" I feel flattered to notice she is equipped with magneto-electric speed indicators constructed on the line of my invention "Recorders of Speed of Driven Shafts" which was described in The Electrical Engineer nearly two years ago.

The instrument differs from the ordinary counters used on ships as it shows at a glance the speed of the shafts *in turns per minute* or miles per hour, the indications being located at different points on the ship. I would suggest to marine engineers that a very desirable improvement is within easy reach, by adding the recording apparatus shown in my patent and driving the paper strip by clock work instead of by the motor shown; or using the entire mechanism shown and adding a supplementary pencil to be driven back and forward across the recording paper every half hour. This would leave a perfect log of the engineer's movements, showing the speed of the screw, back or forward, standing or racing at any second of the trip.

J. C. Henry.

Colorado Springs.

INDEPENDENT EXCITATION FOR TURBINE DRIVEN GENERATORS.

I have read with great interest an article in your issue of July 17, 1895, entitled: "Steady Voltage for Turbine Driven Railway Generators.—The Ahearn Method." The method is very good, but it seems to me that you would have hesitated in calling it "The Ahearn Method" if you should have happened to remember the following paragraph from my paper: "Practical Notes on the Electrolytic Refining of Copper," read before the American Institute of Electrical Engineers, June 6, 1892:—

"A few words as to electric generators may not be out of place. The author prefers separately excited machines for the reason that they cannot be reversed and other incidental advantages. When water power is used as a prime mover a good deal of trouble has been experienced in the regulation of the wheels. As a matter of fact, there is no water governor in existence which will regulate so perfectly as the governor of a modern automatic engine under varying loads. By running all the exciters from an independent prime mover (either water or steam) the strength of the fields of the generators will be uniform at all times whether there are fluctuations in the external circuit or not; the strength of the field of the generators which, with self-exciting machines, is subject to the fluctuations in the external circuit, and is a variable, becomes a constant. The author proposed this arrangement over three years ago for railway and power stations with the very best results."

It will readily be seen that what you please to term "The Ahearn Method" was suggested and tried by me as early as 1889. At the time I first suggested this method, I discussed with my patent attorney the question, whether it was a patentable invention or not and he stated most positively that it was not. I simply mention this as a matter of record.

You will greatly oblige me by publishing this communication in the next issue of your paper.

F. B. Badt.

Chicago, Ill., July 22, 1895.

APPRECIATION OF THE "DATA SHEETS" IN NOVA SCOTIA.

The second of your "Data Sheets" is to hand and I am very much pleased with it. To use the historic remark of King Henry VIII. "You have got the right sow by the ear." The local telephone manager was trying to decide what paper to subscribe to, but on seeing your first Data Sheet, it settled the question, and I sent his name to my news agent along with an order for a morocco case for each of us. You will please add my name to the list of those willing to give a helping hand. I am collecting some data on "Illumination," that is to say the effect of various ways of lighting stores, halls, churches, etc. Any of this you are welcome to. It is gathered from and applies principally to the class of work met with in the medium and smaller sized plants, but my experience is that those in charge of these plants throughout the country are more in need of "data" and "wrinkles" than those in the large cities. I would suggest that as soon as practicable you publish an expansion of the general classification, as there are probably many like myself who would like to index their own notes under the same system. I have been using the card catalogue method of keeping notes and have now cut out of the sheet in the advertisement, page XV, of your current number, (July 17) and attached it to my card box as an index for them, and shall number the cards to match. I have also some notes on the material, time and labor required in reconstructing pole lines. Let me know if any of the above data will be of service to you and when you will want it. Wishing you all success in this venture.

Fred. A. Bowman.

New Glasgow, N. S., July 22, 1895.

ELECTRIC LIGHT AND TROLLEY WIRES AS LIGHTNING PROTECTORS.

It is a singular and interesting fact that during the present summer, while severe lightning storms have been of frequent occurrence in all directions, and within 10 or 15 miles of this city, yet the city itself has been remarkably free from electrical disturbances, so much so that, up to this time, not a fuse has been blown nor an arrester plate grounded by lightning in our switch this season.

During the summer of 1894 this city was also remarkably free from severe lightning. In this respect the summer of 1894, and more especially that of the present year, are in marked contrast to previous years, when the blowing of fuses and burning of instruments were of frequent occurrence. The inquiry suggests itself whether the extension of heavy trolley and light currents in all directions through the city during the last two years is not responsible for this immunity from severe lightning storms?

D. B. Grandy,
Postal Telegraph Co.

St. Louis, Mo.

[The observations of our correspondent are in accord with previous experience under like conditions. There can be little doubt that the network of overhead wires within cities acts as a protection against lightning to a considerable extent.—Eds. E. E.]

PRAISE FOR "THE ELECTRICAL ENGINEER" DATA SHEETS.

Mr. Horatio A. Foster writes us: "Please let me congratulate you on the new Data idea. It strikes me as being better than any pocket book idea, mainly because it may be always kept up to date." Dr. Louis Duncan, of Johns Hopkins University, writes: "The Data Sheets are fine." Mr. P. B. Delany says: "The Data Sheets are a happy thought, and cannot fail to nail the old and hook new patrons of the "Engineer." Mr. A. E. Braddell, the insurance electrical expert of Philadelphia, orders a filing case and writes: "Congratulate you; great brain to evolve the idea."

TELEPHONY.

THE EASTERN ELECTRIC CO.'S TELEPHONE SWITCHBOARD AND OTHER EXCHANGE APPARATUS.

NEXT in importance to the transmitter and receiver in a telephone exchange system, is the switchboard. This constitutes as it were the nerve centre of the whole system and any delay or derangement at that point must always work to the disadvantage of the subscriber. In these days of strict enforcement of patent rights it is not easy to evolve improvements of a non-infringing nature, but this very state of affairs has stimulated invention to a more than ordinary degree, and among the apparatus which has recently been constructed of this nature is the telephone switchboard of the Eastern Electric Co., of Philadelphia, built under the Gould-Smith Patents.

Before entering into a description of the various interesting details of the new board it may be well to point out the fundamental principle upon which it is based, which is expressed perhaps as well as could be done in the claims of two of the Gould-Smith patents. One of these reads as follows: "In a switchboard system, the combination with the main line of a movable terminal and a line-opening mechanism substantially as described, whereby the terminal is automatically moved to open the line, and is held open upon a current passing through the line, substantially as set forth." The other claim reads:

"In a switchboard system the combination with a metallic circuit line having two contact points connected with different portions of the line, of a movable contact piece which connects both contact points when in its normal position, thereby completing the circuit and shifting mechanism substantially as described connected with said contact piece whereby the latter is automatically separated from said contact points by a current passing through the line thereby opening the line, substantially as set forth."

FIG. 1.—THE EASTERN ELECTRIC TELEPHONE SWITCHBOARD.

Reduced to actual practice this means that when the subscriber rings up "Central" the very act of ringing opens his line, a visual signal is displayed to the operator at the Central Office, and the subscriber's bell stops ringing. He thus knows absolutely that his call has been registered. Should the subscriber's bell continue to ring, he would know at once that his line was grounded or out of order; hence he may notify the manager promptly and save valuable time for himself. The switch-board also automatically informs a subscriber if his line or instruments are defective, and thus each subscriber tests his own line.

FIG. 2.—THE EASTERN ELECTRIC TELEPHONE SWITCHBOARD.

Secrecy of communication has always been a desideratum in telephonic exchange work, and in the present system it is impossible for an operator to go in on either of the lines locked together, as shown in Fig. 2, with plugs 38 and 61 locked in 61 terminal. It follows from this that one never hears the operator asking "Are you through?"

Two moves of the operator to connect, and two to disconnect, from the first call of the calling subscriber to the replacing of the plugs to normal position, after the ring off, is all that is required with this system; that is, a number nearly three times less than is required with the boards in use at present, and evidently resulting in just so much quicker service.

The fact that each subscriber has an individual cord, enables the operator to connect 100 per cent. of the calls; or in other words in a 100 terminal board, 50 of the subscribers can call up and be connected with the remaining 50. This reduces the "busy" calls to a minimum, as the operator is not forced to say "Busy" to a calling subscriber for want of connecting cords, when in reality the subscriber asked for is not using his line at all. Thus each subscriber's private line is extended throughout the system, ready for instant use, and it is not necessary for the operator to search for idle connecting cords, even if the system admitted of her doing so.

Any current of sufficient strength to attract the armature will instantly and automatically open the line, the same action taking

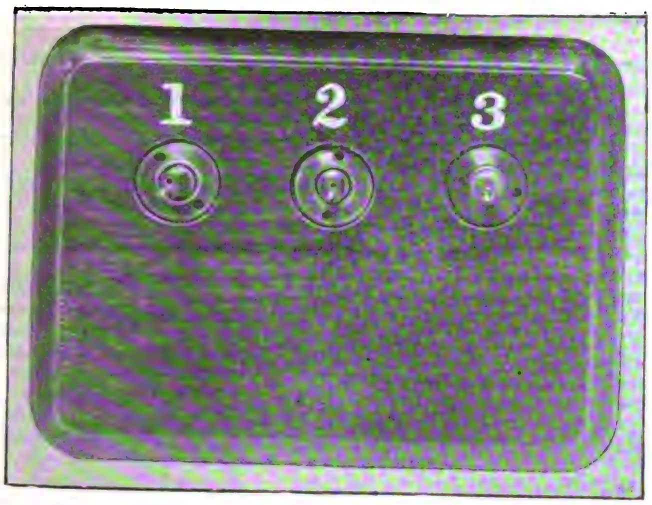


Fig. 3.—Plugs at Normal Position.

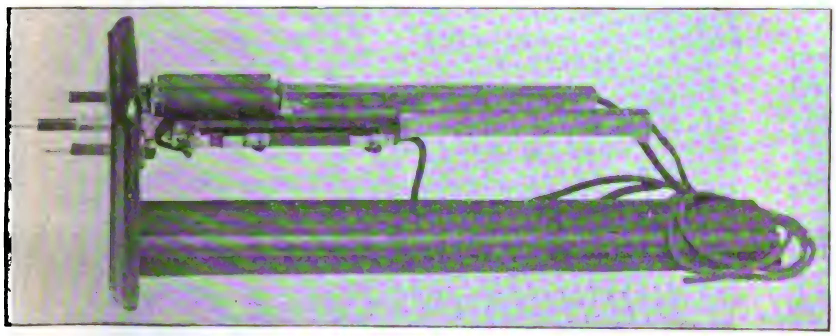

Fig. 4.—Plugs Showing Subscriber's Call Registered and Line Automatically Opened by Subscriber's Ring.

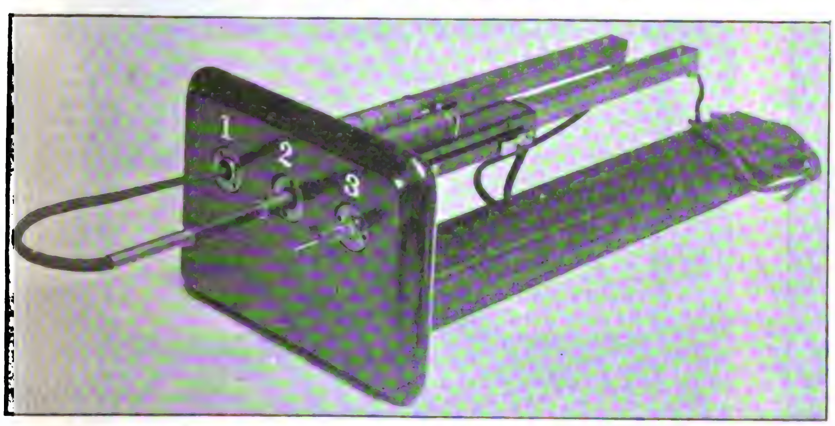

Fig. 5.—Plugs Coupled and Pushed In.

Fig. 6.—The Completed Connection.

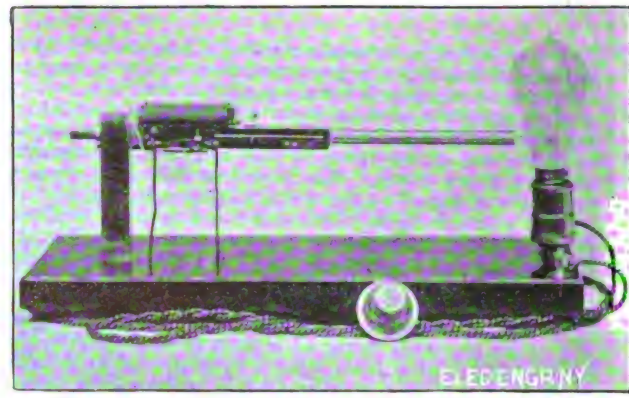

Fig. 7.—Test of Fire Proof Quality of Subscriber's Terminal.

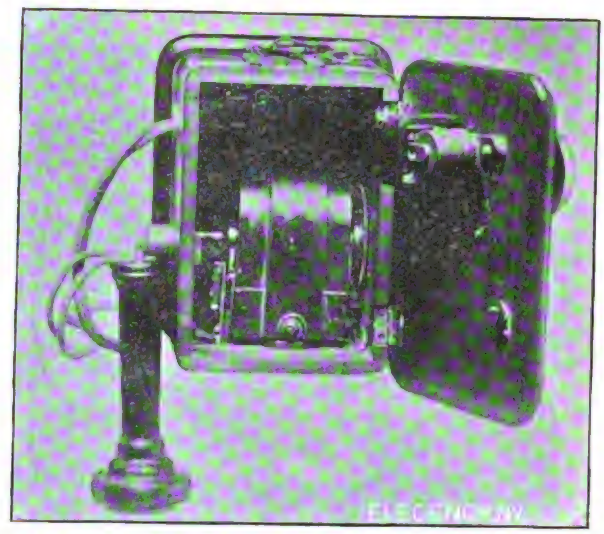

Fig. 9.—Gould Receding Hook, Modified Form.

Fig. 10.—Gould Push Button Desk Set.

place as when a subscriber calls. This is all the lightning arrester necessary, as any current that is not strong enough to attract the armature, is not a dangerous one.

This principle has been thoroughly tested in actual practice as regards lightning and the result is highly satisfactory, not a coil being burned out by lightning that had been playing on the board during a heavy storm. The same test held good when a 110 volt current was turned on the terminal shown in Fig. 10.

The principle upon which this board is built enables it to be constructed and put together one terminal complete at a time; in fact it cannot very well be built any other way, each terminal being separate and distinct in itself.

The engraving Fig. 1 shows a full front view of the "Individual Cord" metallic circuit switch-board for 100 subscribers' terminals, the space occupied being 14 square inches. The terminals are secured 1¼ inches from centre to centre of hole, bringing the plugs the same relative distance (1¼ inches) from each other in every direction. The front piece with 100 perforations shows the small handles attached to the device that enables the operator to manually take the slack from the telephone cord, thus avoiding the weight patent. The pedal at the bottom of the board serves as a foot push to ring subscribers' bells, by depressing it at the proper time and ringing the called subscriber.

It will be noticed that there are no annunciator aprons, clearing-out annunciators, levers, push-buttons, or any other similar device whereby the subscriber signals, is answered, is connected with another subscriber, or rings off. The individual plugs and their connection with their respective terminals perform all of these functions, and two plugs connected together form a complete and absolutely secret metallic circuit between two subscribers.

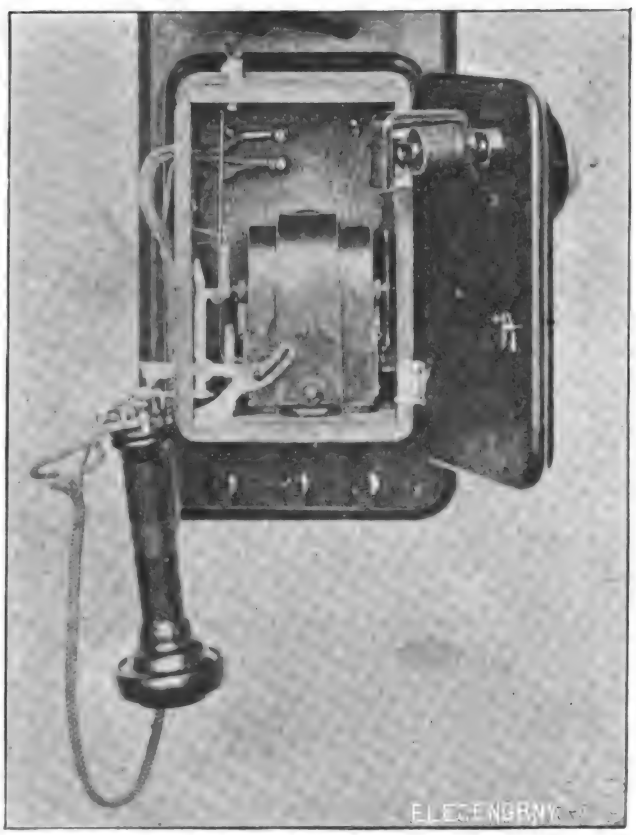

Fig. 8.—Interior View Showing Gould Receding Hook.

The side view Fig. 2, of the 100 terminal board shown in Fig. 1, gives a good representation of the position of the connecting plugs and cords in their four different positions, as shown in Figs. 3, 4, 5 and 6. These show respectively the normal position, the subscriber's call registered, two subscribers connected together and the subscribers rung off.

Referring in Fig. 1, to plug 94, this shows the subscriber's call registered. 68 and 10 are connected and ready to be locked in 10 terminal. 88 and 61 are connected, locked and talking through 61 terminal. 81 and 100 shows number 100 rung off; the remainder of the plugs are normal.

It will be noted that there are a number of holes unfilled by terminals. Thus any subscriber's terminal can be put in or removed at will, without interfering in the slightest degree with any other one in the board, as there is no electrical or other connection between the two terminals until the two plugs are coupled together.

Referring again to Fig. 3, this shows a front view of the board at rest, with plugs at normal in the three terminals.

The side view, Fig. 4, shows No. 2 subscriber's call registered and the line automatically opened by the subscriber's ring. The advanced position of plug No. 2 will be noted. The operator now presses No. 2 plug back as far as she can, thus looping in the telephone circuit and asks: "Number?"

After ascertaining the number wanted, the operator couples the two plugs together as shown in Fig. 5 and pushes them in, when they reach the point where the operator spoke to the subscriber in Fig. 3 after he called. A depression of the foot push shown in Fig. 1 cuts out the telephone circuit and cuts in the generator circuit, thus ringing the called subscriber's bell. This is done as the operator pushes the plugs by the contact points towards the point of locking.

Fig. 6 shows the position of a completed connection, as finished, from the point of ringing the called subscriber, as shown in Fig. 5. The plugs are now locked in, and the operator cannot loop in on the connection until the subscriber rings off. When the subscriber rings off, and the automatic action takes place, the plugs are thrown out of the terminal in which they have been locked and take the same position as shown in Fig. 5, which is the operator's notice that they are through talking.

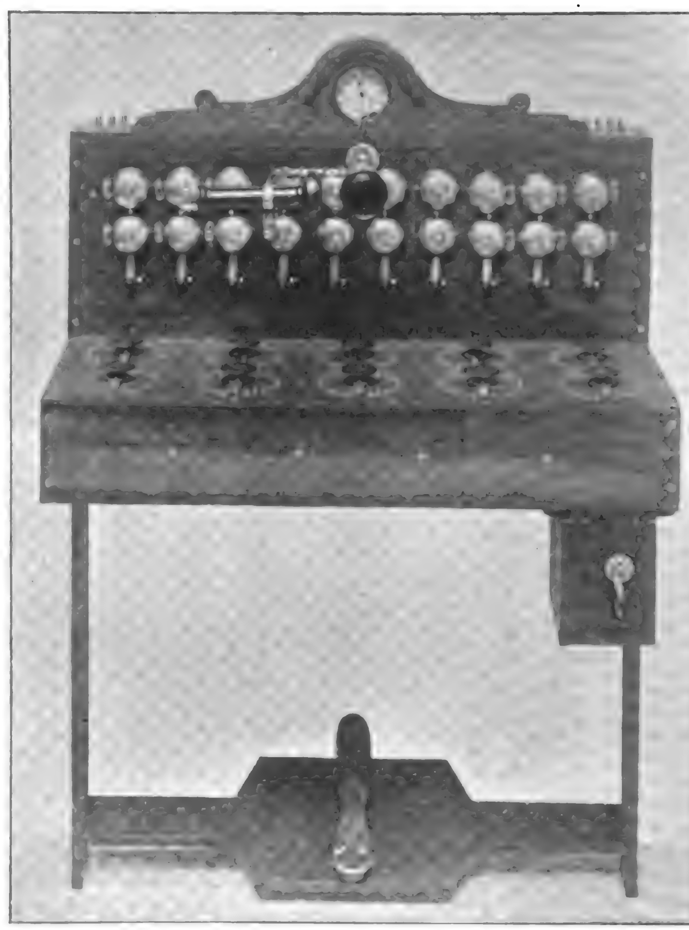

Fig. 11.—Eastern Electric Territorial Board.

When a connection is locked in, as in Fig. 6, the coils of No. 1, are shunted, and No. 2 are in circuit for clearing off. The act of withdrawing any one of the cords from a terminal, shunts those coils.

Fig. 7 represents one subscriber's terminal arranged to demonstrate the point that electric light or other high tension currents will not destroy the coils or set fire to the switch-board. It is connected up in series with the coils and a 16 c. p. lamp by the usual attachment. During a recent test, the automatic action on the terminal (when the 110-volt current used in the building was turned on,) was so quick that the lamp failed to show the slightest glow of light. The lamp was prompt to light, however, when the plug was pushed in and the line held closed.

Fig. 8 shows an inside view of the Gould receding hook, a forcible reminder to the subscriber to ring off when through talking. When the subscriber removes the receiver, the hook automatically

disappears in the case of the bell, and will not appear again until the subscriber turns the crank and rings off, when the hook for the reception of the receiver re-appears. There is thus nothing to bang the receiver on until the subscriber rings off.

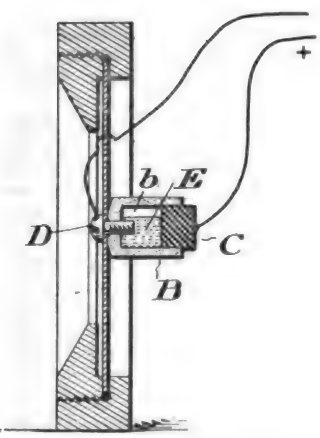
A different arrangement of the same principle, with an additional feature is shown in Fig. 9. When the subscriber rings his bell, the receiver is released by that act, and he cannot replace the receiver without ringing off.

Fig. 10 represents the Gould push button desk set for interior use, with either battery or magneto circuit, using but two wires for calling, return call, and talking circuit.

Fig. 11 shows the territorial or long distance board which has been in practical use for some time past. It is designed for metallic circuit, the extra binding post at the top being ready for a ground or the second wire for the metallic circuit. One half of the terminals can be used for ground circuits and the other half for metallic and connections can be made between them. The terminals are so constructed that the operator can loop in on any connection without interrupting. These boards are made with the automatic action or fixed ground.

THE PAIGE LIQUID TELEPHONE TRANSMITTER.

WHERE solid substances alone have been employed, either in the form of an electrode or in the form of a plurality of bodies interposed between a moving and a fixed electrode, the necessary variations have, in accordance with the usually-accepted theory, been produced by variations of pressure or in intimacy of contact between the approximate surfaces. Where, on the other hand, liquids or plastic bodies have been interposed between the moving and the fixed electrodes the variations of resistance have been effected by the physical approach or recession of the moving electrode toward or from the fixed one, and the corresponding



THE PAIGE LIQUID TELEPHONE TRANSMITTER.

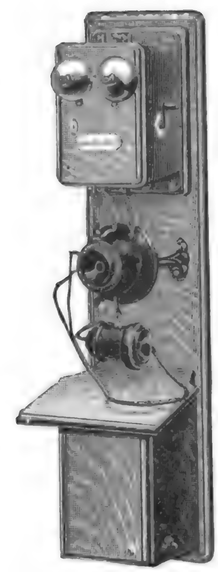
changes in the length of circuit, extent of immersion, or other consequences of the movement of one electrode relatively to the other.

Mr. Arthur E. Paige, of Philadelphia, in a patent just issued to him, states that he has discovered that the necessary modification of the electric current for the reproduction of sound-vibrations can be accomplished by the mere agitation of a liquid conductor, such as mercury, interposed between two separated electrodes, which are maintained in unvarying relation to each other during the transmitting operation.

A transmitter constructed on this principle is shown in the accompanying engraving. As will be seen, the diaphragm carries at its centre a vulcanite cup B, secured to the diaphragm by means of a metallic screw D which penetrates into the interior chamber *b*, within the cup. A plug C, made of carbon, is fitted tightly into the mouth of the cup, so as to form a completely-inclosed chamber *b*. This chamber is partly filled (before the insertion of the carbon plug) with mercury, as indicated at E. The terminal wires of the telephone circuit are connected respectively to the screw D and the carbon plug C, so that the screw and the plug constitute two solid electrodes or terminals of the circuit, which when once set up at the proper distance remain absolutely fixed in their relation to one another. The circuit across the interspace is of course completed by the mercury E.

Mr. Paige has found in operation that the effectiveness of the instrument is enhanced by coating the surface of the mercury by a mere film of certain materials, which are capable of adhering thereto, such as graphite, of the kind ordinarily used as stove-polish, or glass, each being in the form of an impalpable powder. From the different electrical characteristics of these two materials it would seem that the modification of the mercury by them must lie in some direction which is not directly cognate to the conducting or non-conducting character of this film. To produce the effect the merest pinch of the powdered material may be dusted upon the mercury and the surface be then blown upon vigorously until every particle which can thus be removed has been blown away.

THE "COLUMBIA" TELEPHONE.



Columbia Telephone Set.

We publish herewith a cut of the new "Columbia" telephone now in use by the Capital Telephone and Telegraph Co., between Sacramento and Folsom, California, on the same pole lines as the high potential power circuits (see page 115, this issue of THE ELECTRICAL ENGINEER). The apparatus has been on the market some time, but has lately been radically overhauled, remodeled and improved by Mr. William M. Miner, well known as an expert inventor and electrical engineer, who has now become chief electrician for the makers of it, the Columbia Telephone Manufacturing Co. of No. 138 Front street, New York city. Mr. Miner has reorganized the whole electrical department of the Company, and the telephones are giving remarkable satisfaction, as to durability, clearness of transmission, freedom from inductive disturbance, and permanence of adjustment.

The Columbia Company has been shy of mere daily newspaper notoriety, but has in no sense been idle, its output of instruments having steadily increased until it could in some degree keep pace with orders. Besides supplying instruments, the Company is now building and equipping switchboards guaranteed to be perfectly free from infringement. One for several hundred subscribers has already been installed in Sacramento, to take care of over 500 subscribers secured there already by the local Capital Telephone Co.

THE CENTRAL UNION "BOGY."

THE Central Union Telephone Co. is issuing the following pithy little notice to those who venture to use other telephones than its own:—

Subject: Infringement Notice.

CENTRAL UNION TELEPHONE COMPANY
GENERAL OFFICES.
Ashland Block, Randolph & Clark Streets,
CHICAGO.

............, ..., 1895.

....
....

Dear Sir:

THE CENTRAL UNION TELEPHONE COMPANY having within the County of...... , State of.........., the exclusive right for the American Bell Telephone Company's appliances covered by its patents; and having erected and now operating its telephone lines and equipment in reliance upon such rights, hereby gives you the following notice:

The American Bell Telephone Company owns Letters-patent No. 463,569 granted to Emile Berliner, November 17, 1891, for a combined telegraph and telephone, covering all forms of microphone transmitters or contact telephones.

Respectfully,
CENTRAL UNION TELEPHONE COMPANY,
By H. H. MATLOCK,
Superintendent.

TELEPHONE NOTES.

SANDUSKY, O.—B. I. Lamb has been appointed to superintend the construction of the new Sandusky telephone line.

MARTINSVILLE, IND.—The Martinsville Telephone Company has been formed; capital stock, $7,000.

DECATUR, ILL.—The Harrison Telephone Co. plant at Decatur has been sold to satisfy a judgment for $9,488.18.

MEMPHIS, TENN.—The Standard Telephone Co. is seeking a franchise in Memphis.

LOGANSPORT, IND.—The City Council has granted E. B. Overshimer a franchise to construct a new telephone system here. The new plant will be in operation by Oct. 1.

LONOKE, ARK.—The Southwestern Telephone and Telegraph Company has been granted a permit by the Lonoke Council to erect its posts and wires. The line will be erected to Devalls Bluff this month.

BEL AIR, MD.—The poles for the Harford Telephone Company have reached Havre de Grace, and the wires have been strung. Connection has now been made with Churchville, Carsins' Run, Aberdeen and Bel Air.

NORTHAMPTON, MASS.—The offices of the New England Telephone and Telegraph Co. have been seriously damaged by fire.

WESTMINSTER, MD.—The Chesapeake Telephone Company is re-building its line from this city to Baltimore.

INDIANAPOLIS, IND.—The Universal Telephone Company are putting in a system of their telephones for Schnull & Co.

SHERBROOKE, QUE.—The Sherbrooke Telephone Company, anti-Bell, has declared a half yearly dividend of 3 per cent.

MASSILLON, O.—At the meeting of the stockholders of the Farmers' Telephone Company it was decided by a unanimous vote to increase the capital stock from $10,000 to $20,000.

NEW HAVEN, CONN.—The Southern New England Telephone Company's dividend for the quarter ending June 30 is announced as 2½ per cent.

APPLETON, WIS.—Frank Merriman, manager of the Appleton and Kaukauna telephone exchanges has resigned and his place will be filled by Chas. Avery, of Stevens Point.

FORUM, N. D.—The Telephone Co. have requested and were granted permission to put in a water motor to generate their own current. They grant the city the use of two telephones in return for the water.

BUTTE CITY, MONT.—C. A. Davidson, formerly of the telephone service at Anaconda, has taken the position of manager of the Rocky Mountain Telephone Company here, vice F. W. Groff, resigned.

DETROIT, MICH.—It is stated that the Brown telephone company will give each alderman and the head of each city department a telephone free of cost, if the Brown ordinance becomes a law.

EVERETT, MASS.—It is very probable that Everett will soon have a new local telephone company. H. H. Hunt, George H. Conant and H. C. Pierce, the sole agents for the Century Telephone Company, are at the head of the enterprise.

LA CROSSE, WIS.—The new La Crosse Telephone company has entered into a contract with the American Telephone company of Kokomo, Ind., for a complete central station outfit with a 500-drop switchboard and as many long-distance telephones. The contract price will almost reach $10,000.

YORK, PA.—It is proposed to apply to the state for a charter for an intended corporation to be known as "The Octoraro Telephone and Telegraph Company," the object of which is to construct a system of telephone wires and instruments in Chester, Lancaster and York counties.

FULTON, IA.—The Whiteside-Harrison Telephone Co. has finished its canvass for subscribers and has 115. It has subscribers also in Sterling, Morrison, Prophetstown, Tampico, Spring Hill, Lyndon, Fenton, Erie, Albany, Gardenplain, Fulton, Malvern, Coleta and Penrose, this county, and Clinton, Iowa, and it intends to run its line into every town in the county.

KENOSHA, WIS.—The National Telephone Construction company of Milwaukee, has presented an ordinance to the common council granting a franchise for the erection and maintenance of a complete metallic circuit long-distance telephone system and asked that it be passed. The ordinance states that the system must be completed and in full running order within six months and is not to cost more than $30 per year for business telephones and $18 per year for residences.

NEWPORT, R. I.—The Nixon Telephone and Electrical Supply Company of Providence has finally succeeded in establishing here a line of its new telephone system. The system is what the company calls its "Railroad Telephone System" and is intended to cover a railroad section of sixty miles or more, the wires starting from the train despatcher's office and extending along the side of the tracks, with the company's patent box connections, at, say, every 500 feet.

LEWISBURG, PA.—A telephone company, with a capital stock of $10,000 has been organized in Lewisburg. The purpose is to extend the lines to every part of Union County, the central station being at Lewisburg. Communication will be opened with Winfield, New Berlin, Mifflinburg, Millmont, Hartleton, Laurelton, Forest Hill, Kelly Cross Roads, Allenwood and all intermediate points. The officers are J. T. Baker, President; C. H. Hassenplug, Secretary; C, F. Shaffer, Treasurer.

GOLDEN CITY, MO.—A meeting of the stockholders of the Golden City Telephone Company has been held and it was decided to build a line to Lockwood, thence connecting with Greenfield. The contract has been let to the Dunlap Construction Company of Springfield, Mo. Several big telephone projects are now on foot. A line is being run from Greenfield to Stockton, thence connecting with Bolivar, Humansville, Fair Play and other points. A company will be organized to build a line to Jericho, twenty miles north of this point. Southwest Missouri will soon be connected by a perfect network of telephone wires.

ASHLAND, KY.—H. H. Fowler, manager of the East Tennessee Telephone Co., has received a new switchboard.

LITTLE ROCK, ARK.—The capital stock of the Little Rock Telephone Company has been increased to $100,000.

COLEBROOK, N. H.—The Colebrook, Stewartstown and Connecticut Lake Telephone Co. has declared a dividend of 6 per cent.

BARABOO, WIS.—The Wisconsin Telephone Company has asked for a franchise from the Baraboo City council.

ALBANY, N. Y.—The Home Standard Telephone Company of Albany, N. Y., has been incorporated. Capital stock, $350,000.

ISHPEMING, MICH.—The Marquette County Telephone company has begun stringing wires for its new telephone system.

EAGLE GROVE, MINN.—The Phoenix National Telephone Company, of Indianapolis, has been granted a franchise to put in an exchange in the city.

SHEBOYGAN, WIS.—The ordinance granting to Messrs. End, Winter and Johann a telephone franchise has been given a second reading and passed by the unanimous vote of the council.

HUNTINGTON, KY.—Huntington's new Mutual Telephone Co. is assured of success, as contracts for the placing of the exchange have already been let to the Old Dominion Construction Co., of Richmond.

Mr. W. F. BURNS has passed through San Francisco on his way to Japan, on behalf of the Standard Telephone Co., which has, it is asserted, an exclusive concession for certain telephonic work in the Empire.

SAGINAW, MICH.—A plan is on foot with the board of trade in the background looking to the organization of a new local telephone company, composed of people residing in the valley cities, Saginaw, Bay City and West Bay City.

LANSING, MICH.—D. A. Reynolds has notified the Common Council of the acceptance of the franchise recently granted the Lansing Telephone Exchange and presented the required bond to hold the city harmless for all damages which may result from accidents occasioned by the company.

JASPER, IND.—The Jasper County Telephone Company has been incorporated with a capital stock of $8,000. Those back of it are: James T. Watson, C. C. Sigler, E. L. Hollings and Delos Thompson, all of Rensselaer, and the system will include Jasper, Newton, Benton, Porter, Lake, White, Pulaski, Starke, Laporte and Tippecanoe counties.

PLYMOUTH, N. H.—The Plymouth & Campton Telephone Exchange Company has purchased the property of the Franconia Telephone Company, including a service of 25 miles through the famous Franconia notch. This will give through telephone service up the Pemigewasset valley through the Notch to the mountains beyond, a long felt necessity.

DES MOINES, IA.—The Globe Telephone and Construction Company will file articles of incorporation. The capital stock will be twenty thousand dollars and the business will consist of constructing and equipping telephone exchanges. The instrument is the invention of a Hungarian, J. Serdinko, of San Antonio, Texas.

YARMOUTH, ME.—Articles of incorporation have been filed for the Yarmouth Telephone Co., which has been organized for dealing in electrical goods, constructing telephone lines, various tools, etc. The capital stock is fixed at $10,000, with $80 paid in. The incorporators are Albert H. Coombs, John Coombs and Geo. E. Coombs, all of Yarmouth.

FARMINGTON, ME.—The annual meeting of the Dirigo Telephone Company of Maine has been held, and the following officers elected for the ensuing year: President, George M. Seiders, Portland; secretary and treasurer, Charles E. Marr, Farmington; general manager, Seth E. Beedy, Farmington. It was voted to establish headquarters for the company in Portland, and also to manufacture telephones and telephone appliances there.

NEWARK, N. J.—The Newark Mutual Telephone Company has had its articles of incorporation recorded. The company will do a general telephone business in this city. The capital stock is placed at $300,000 and business will be commenced with $1,000. The incorporators are Earnest J. Foord, of Jersey City; P. Justus Atkinson, of New York City, and Samuel L. Boyd, of Brooklyn, N. Y.

FRAMINGHAM, MASS.—The new Framingham Telephone company has organized for business, and chosen Michael F. Maher, of Saxonville, president, H. A. Worthley of Boston treasurer, Geo. H. Conant of Boston secretary, and H. H. Hunt and H. C. Pierce both of Boston, the other two members of the board of directors. The company has received a franchise to locate in Framingham and the Natick selectmen have held a hearing for one in that town. If the latter is granted, the two plants will be run under one charter. The company is capitalized for $15,000.

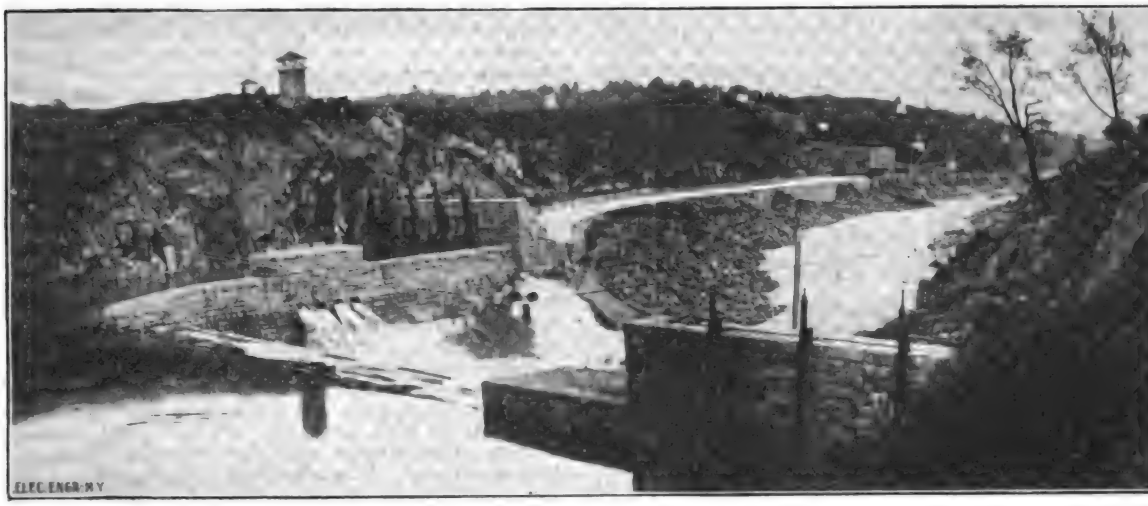


FIG. 1.—DAM AND CANAL OF THE FOLSOM-SACRAMENTO ELECTRIC TRANSMISSION PLANT, FOLSOM, CAL.

INAUGURATION OF THE FOLSOM-SACRAMENTO 3-PHASE POWER TRANSMISSION PLANT.

ON July 14 current was transmitted for the first time over the new 3-phase transmission plant between Folsom and Sacramento, Cal., and has continued in successful operation from the start. In our issue of February 13, 1895, our special correspondent, Mr. H. Guy, gave the first details of this interesting installation which constitutes one of the largest enterprises of its kind in the country and which cannot fail to have a marked influence on the future of power transmission in California.

The power is derived from the water of the American River confined by a dam 650 feet long, 24 feet wide at the top and 87 feet wide at the bottom and 89 feet high at the highest point. The storage basin thus formed is 3½ miles long and has a capacity of 13,000,000 cubic yards. A canal runs from the dam along the side of the river down to the power plant and mill sites, opposite Folsom. This canal is 50 feet wide and 8 feet deep, carrying 85,000 cubic feet of water per minute. Its walls are built in large part of solid masonry, the work having been done largely by prison labor under a contract with the State.

The river has a fall of 82 feet from dam to power house, and of this fall seventy feet can be utilized for power, producing when fully utilized 10,000 horse-power.

The plant now installed has a capacity for generating 4,000 H. P., and two of the four generators necessary to produce this are now placed, and two more are on the ground ready for setting on the foundations. Our engraving Fig. 2 shows the power house of the Sacramento Electric Power and Light Co., which covers a cut in the solid rock 60 feet deep, 100 feet wide and 150 feet long.

The discharge of the water from the canal into the power station is regulated by four gates, so that any one of the four 1,000 horse power generators can be used independently of the others; Fig. 3 shows the penstocks and turbines. These latter of the McCormick type are of 1,200 H. P. capacity each and run at 350 R. P. M. under a head of 55 feet. They were built by the S. Morgan Smith Works, of York, Pa., under contract with the Pelton Water Wheel Co. of San Francisco.

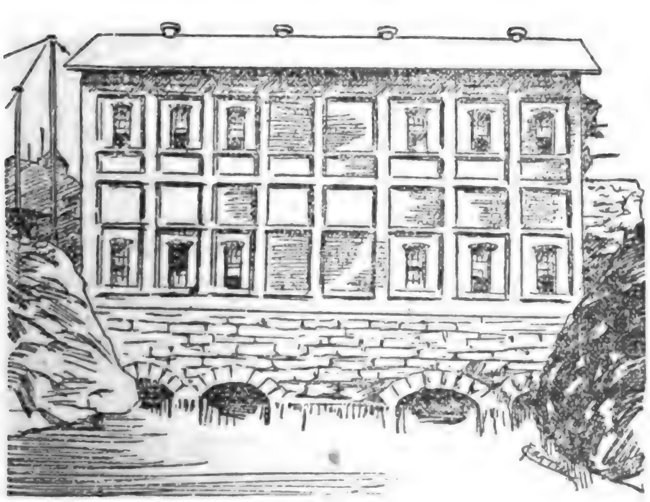

FIG. 2.—THE POWER HOUSE AT FOLSOM.

The dynamo room is arranged for four 1,000 H. P. 3-phase generators built by the General Electric Co., coupled direct to the turbine shafts. These machines weigh 40 tons each and are the largest 3-phase machines built thus far. They deliver current to step-up transformers which raise the potential to 11,000 volts on the line.

The double pole line from Folsom to Sacramento is 22½ miles long. The poles are of red cedar, 40 feet long, 16 inches in diameter at the butt; they are set 105 feet apart and carry five cross arms, 4 x 4 inches by 7 feet long, placed 16 inches one above the other. At present the three top arms each carry two No. 1 bare copper wires, and the 3-phase current is delivered at Sacramento to step-down transformers. The transformed current is led to three 3-phase motors of 300 H. P. capacity each which drive street railway generators and arc light machines.

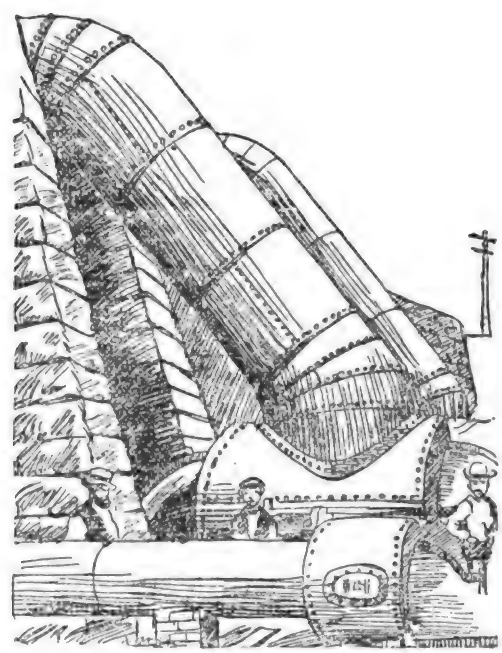

FIG. 3.—PENSTOCK AND TURBINES.

An interesting feature of the installation is the telephone line, which connects the power house at Folsom with the station at Sacramento. The liability to induction at first deterred the managers of the enterprise from stringing the telephone wires on the same poles as the power transmission wires, but Mr. Chas. E. Severance and Mr. V. J. Mayo, E. E., of the California Telephone and Construction Co., of San José, Cal., the agents of the Columbia Telephone Co., in California, undertook the work. The tele-

phone conductors are placed on the lowest pole arm and 40 inches from the nearest power conductor. By a skillful system of transposing the wires no trouble whatever is experienced from induction, and the articulation of the Columbia telephones over the distance of 22½ miles is perfectly clear. Considering the length of the line and the great proximity of the disturbing wires the feat accomplished is well worthy of notice.

LONG DISTANCE TRANSMISSION AT 10,000 VOLTS.

(The Pomona Plant.)—II.

BY GEORGE HERBERT WINSLOW.

There are two transmission lines, one 13¾ miles long which supplies Pomona, and another 28¾ miles long, which supplies San Bernardino. Each line consists of two No. 7 B. & S. gauge wires. The joints in the wire are made with McIntire connectors. To further improve the joint the ends of the wires were bent back side by side and soldered together. After the Pomona line was completed and the first ten miles of the San Bernardino line was put up, the supply of connectors ran out, and the regular telegraph joint was substituted. The conductivity was assured by soldering as before.

The wires are supported upon large double-petticoat flint-glass insulators designed for this plant. These insulators are of perfectly clear flint-glass, which gives a better surface-insulation than is attainable with any other kind of glass.

It was at first proposed to use oil insulators. The reason they were not used was because the glass companies which had undertaken to furnish them found on trial that they could not make them without considerable experimenting, which would have delayed the installation of the plant. This was no doubt fortunate, as the country through which the line passes is subjected to hot, dry winds which not only blow dust onto the insulators, but also inside them, and during the day the sun beats on the insulators until they become so hot that they nearly blister one's hands. If oil were used under these conditions it would soon evaporate and thicken, and become filled with dust. It would therefore seem undesirable to have used oil insulators in this case, or to use them in any other until an increased voltage makes them necessary, and the transmission of greater amounts of energy over the circuits justifies the additional expense necessary to keep the insulators in good condition.

The Stillwell regulator has long been recognized as a valuable adjunct to the central station operating a number of feeders of different lengths from a single dynamo. Its utility is still greater in a system of long-distance transmission in which, as was the case in this plant during its first year of operation, the transmission circuits are supplied from one dynamo, since it is not practicable to install such a system so as to operate with small line-loss and therefore means must be provided to compensate for the large differences in the pressure at the ends of the lines. The use of regulators at the power-house was impossible while but one bank of raising transformers was used for the two circuits. Even when it became possible by the use of separate banks of transformers, it was still undesirable because the attendant at the power-house would often have to work both the regulators simultaneously to properly compensate for changes in load, and his attention would be required by the regulators at exactly the time he should be free to attend to the generators and water-wheels. A regulator was therefore placed at each sub-station, as already stated. These are each of 2,000 lights capacity and have a range of 10 per cent. up, and 10 per cent. down. This variation of 10 per cent. (100 volts) is divided into 14 equal parts, so that each step corresponds to 7.1 volts. The distribution from both sub-stations is effected in the usual manner at 1,000 volts for incandescent lighting, the only point of interest being that a considerable number of Helios arc lamps are successfully used on the circuits.

While in use the transformers in the sub-stations give forth a continuous hum which depends for its tone on the number of alternations. This is an excellent indicator for the attendant, whose attention is instantly called to any change in the running conditions of the plant by the resulting change of tone. Its indications not only mark changes which are taking place and which can be detected on the voltmeter, but also give notice of coming changes before there is any other indication of them. It is thus possible to foretell a coming drop in voltage in time to use the regulator and thus keep the voltmeter needle perfectly still, though the voltmeter is a very sensitive instrument, and the regulator is often moved four or five notches. The hum often changes, however, without any corresponding movement of the voltmeter, but the sound is then somewhat different. At rare intervals the switchboard lights will suddenly change slightly in candlepower before any change is noticeable on the voltmeter.

It is noticeable that the needle will often stand for a time perfectly still on the centre, and, on a slight rise in the hum, will start gently rising, never more than three-quarters of an inch, and then as the tone gradually becomes lower, slowly fall back to the centre and stop without passing it. At other times the variation in hum is more sudden and the needle will rise and oscillate above the centre. Again, the needle will oscillate equally about the centre during a regular rise and fall of hum, its movement being apparently due to one impulse and not seeming to be modified by subsequent variations. There is no apparent change in candlepower of the lamps during the voltmeter changes noted. These notes were made while the plant was running at only 5,000 volts, but they were later confirmed when using 10,000 volts. During dry weather there is considerable intermittent oscillation of the voltmeter-needle without there being any change in load or any other apparent cause, while in wet weather, the needle remains perfectly still for many minutes at a time, often for as much as half an hour. A possible explanation of this oscillation may be found in the presence of static charges on the line, due to atmospheric electricity. That the line is often heavily charged from the air is shown by a number of observations. One afternoon a painful shock was obtained on touching the line at the canon end, drifting clouds and a strong wind being noticed in the valley. Again, while using the telephone a report was heard in it so sharp as to cause momentary deafness. Later, after a moderate wind had been blowing for some time, loud reports were noticed on the telephone at long intervals. As the wind became higher the reports came oftener and the intervals between the reports became shorter. It was evident that there was a discharge from the lines through the telephone (which was on a metallic circuit) and that it depended on the rate at which the wind blew. In order to get the strongest effect the two wires were connected in the usual way to the raising and lowering transformers, and one side of the telephone connected to one wire. On connecting the other side of the telephone to ground, a sharp report was heard, and on maintaining the connection there was a sound as of steam escaping at a distance, with intermittent and very faint crackling. If the ground contact was made slowly there was a bright spark before the metals touched, and a loud report. If the fingers were interposed a smart shock was received. By making and breaking the ground connection rapidly, the line was prevented from accumulating a heavy charge, and no spark was visible, though a faint crack was heard. If a slight space was left between the telephone wire and the ground, a spark occurred at fairly regular intervals, and when the space was lessened the sparks became smaller and more frequent. When the wind lessened the sparks and reports became almost imperceptible, but on the wind becoming strong and blustery a large spark was again obtained. When one line wire was disconnected from the transformers at Pomona the effect obtained from grounding that wire was less owing to the reduction in capacity.

These observations, which were made on the Pomona circuit during hot, dry and cloudless weather, show conclusively that the lines were heavily charged by the action of the wind. The wind no doubt blows electrified air and dust against the wires, the latter thereby accumulating a static charge with a rapidity which we have seen depended on the speed of the wind.

BOILER INSPECTION IN MASSACHUSETTS.

Two acts have been passed by the last Massachusetts Legislature with regard to the more thorough inspection of boilers and the qualifications of engineers and firemen in charge of such plants. Boilers are to be inspected at least twice a year, under police control, and the owner is to pay $2 for each boiler inspected, each time. The State has been divided into four districts, and the appointees are: 1st Dist., Thos. Hawley, State House, Boston; 2nd Dist., C. Fergerson, Borden Block, Fall River; 3rd Dist., John H. Wilson, 426 Main street, Worcester; 4th Dist., Geo. H. Lord, 327 Main street, Springfield. The engineers' licenses will be in three grades; the first, unlimited as to size of plant; the second, limited to 150 h. p. and the third limited to 50 h. p.

PRACTICAL MEN AND DATA SHEETS.

Mr. P. Canfield Barney, C. E., Manager, Brunswick, Mo., Water and Light Works, writes: "I think the Data Sheets a great idea, and will be appreciated, I know. * * * Send morocco filing case." Mr. P. P. Crafts, Electrician, U. S. Navy Yard, Boston, says: "I take pleasure in saying that I think the Data Sheets issued in the Engineer, which paper I am strongly addicted to in my spare moments, promise to become a very useful and convenient addition to the electrical engineer's 'pocket account,' who has much business to attend to."

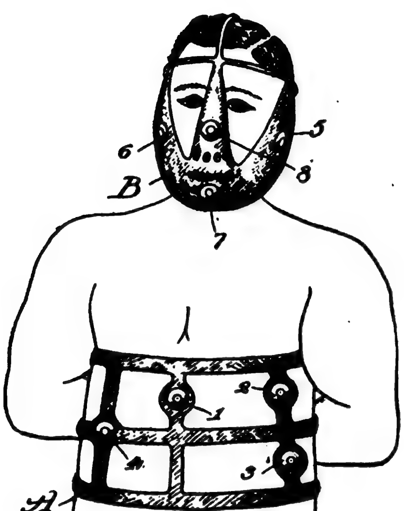
ARC LIGHTS AND CINCINNATI BUGS.

The women residents of fashionable Mt. Auburn, a suburb of Cincinnati, have appealed to the board of administration to have the electric lights abolished and to substitute gas. They say that the arc lights draw bugs which frighten them and keep the children from promenading in the evenings. They also assert in their petition that they had rather live in darkness than have the life scared out of them by buzzing beetles from dusk until bedtime. The petitioner's husbands were not consulted in the matter, so they say, and they are making the request as the wives of taxpayers and as the mothers of timid children.

MISCELLANEOUS.

REGISTERING ARMOR FOR BOXERS.

At last electricity has been brought to the direct aid of boxers, and the followers of the manly art of self defense will hail with delight the device just patented by Mr. Joseph Donovan of Chicago. We will let Mr. Donovan describe his invention in his own language, as follows: It is well known that sparring or boxing is one of the most health-giving exercises in the whole range of athletics, developing endurance, stability of physique, a quickness of eyesight and action, and tending to bring out in its finest and quickest form every muscle of the body. Unfortunately, however, with all these good qualities there is a roughness and a brutality with it, which has thrown it almost entirely outside the pale of legitimate athletics, and to eliminate these rough and



REGISTERING ARMOR FOR BOXERS.

objectionable features entirely to those practicing boxing by padding over all the vulnerable points above the belt and providing each and all of these points with a registering device, so that all blows shall be rung up and registered automatically, thus reducing boxing to a simple test of quickness and endurance, and nothing more, is the principal object of my invention.

We add also the first claim as a warning to would-be infringers: Claim 1. In an armor for boxers, the combination of a jacket or jackets, having a cushion or cushions located over the vulnerable parts of a wearer in use, and means for indicating the number of times each or all of such cushions have been struck, substantially as described.

REPORTS OF COMPANIES.

SCHUYLER ELECTRIC CO.

Judge Thayer, in the Superior Court at Hartford, Ct., has issued an order directing Lewis Sperry, receiver, to sell the property of the Schuyler Electric Manufacturing Company of Hartford and Middletown, Ct.

PECKHAM MOTOR TRUCK AND WHEEL CO.

The annual meeting of the Peckham Motor Truck and Wheel Company was held last week when the following directors were elected: Edgar Peckham, H. C. Soop, Charles Bray, W. H. Wilkinson, J. H. Burton. The following officers were elected: Edgar Peckham, president and treasurer; H. C. Soop, vice president; J. H. Burton, secretary. A semi-annual dividend of 4 per cent. was declared.

SIEMENS & HALSKE ELECTRIC CO.

The Siemens-Halske Company has elected Charles T. Yerkes, son of the street railway magnate, vice-president and a director. W. F. Furbeck, who represents Mr. Yerkes, Sr., in divers corporations, has also been made a director. O. W. Meysenburg, president of the Wells & French Company, and treasurer of the Siemens Company, retains the latter office. The full list of officers includes: President—A. W. Wright. Vice-president—Charles T. Yerkes. Secretary—F. B. Badt. Treasurer—O. W. Meysenburg. Directors—Arnold von Siemens and George Wilhelm von Siemens, of Berlin; O. W. Meysenburg, Charles E. Yerkes. W. F. Furbeck, David B. Lyman and F. B. Badt, of Chicago; Martin Maloney, of Philadelphia.

The number of directors has hitherto been five. This is increased to nine. The new directors are Yerkes, Furbeck, Lyman, trustee of the Grant Locomotive Works; Maloney, the Philadelphia magnate, and Badt, representing Yerkes. The one director dropped is Sir William Van Horne, of the Canadian Pacific Railway, who still retains his old financial interest in the works.

NEFTEL, O'CONNOR & CO.

Duncan Edwards has been appointed receiver for Neftel, O'Connor & Co., corporation, whose office was formerly at Liberty Street, New York city, on the application of John A. Roebling's Sons Company. The company was in the electrical contracting business. Bernard F. O'Connor, the Treasurer of the company obtained an attachment against it some time ago for $11,000. He said the company has assets consisting of office furniture and $20,000 bonds of the Union Electric Light and Power Company of Troy, N. Y., worth probably 25 cents on the dollar, and a claim against the Carbondale and Forest City Railroad Company of Pennsylvania.

HUDSON RIVER GAS AND ELECTRIC COMPANY.

The T. & I. Union Gas Company of Tarrytown, which some two years since absorbed the Excelsior Electric Light Co. of that village, has recently reached out and consolidated with the Dobbs Ferry Electric and the Hastings Gas Co., which latter was formerly a part of this system, and on the 6th of June was incorporated under the new title of the Hudson River Gas & Electric Company. The capital stock of the consolidation is $300,000. The officers are: president, Geo. W. Harris; first vice-president, Charles Russ; second vice-president, William Walker; treasurer, David Silver; secretary, Augustus Konrad. In view of this enlargement of boundaries, the power house of the former Excelsior Electric Company has been extended by an addition on the front to the line of Josephine Street, so as to give room for additional power and machinery. A new dynamo is already in operation and another engine has been ordered. The lines have been extended and contracts have been made with the villages of Irvington and Dobbs Ferry, to be lighted with incandescent lamps placed 200 feet equi-distant, which are now in operation, while the wires will soon be extended to Hastings, thus giving a complete circuit including the villages of Tarrytown, North Tarrytown, Irvington, Dobbs Ferry and Hastings.

EDUCATIONAL.

THE LELAND STANFORD JUNIOR UNIVERSITY.

We have received the fourth annual register (1894-1895), of the Leland Stanford Junior University. The University is located on the Palo Alto estate in the Santa Clara Valley, thirty-three miles south east of San Francisco, on the Coast Division of the Southern Pacific Railway. This University, for the splendid endowment of which California is indebted to the late Hon. Leland Stanford, was formally opened to students in 1891. The list of the faculty is imposing, and the register shows that work of a high standard is being actively and successfully maintained. Dr. F. A. C. Perrine remains in charge of the instruction in the Electrical Engineering Department.

THE UNIVERSITY OF WISCONSIN has conferred the honorary degree of LL.D. upon two men of national engineering reputation, namely, Edwin R. Reynolds, of Milwaukee, designer and builder of the Reynolds Corliss engine and Don J. Whittemore, chief engineer of the Chicago, Milwaukee and St. Paul Railway. Both degrees are eminently deserved, and the recognition of engineering work does credit to the University.

OBITUARY.

SAMUEL LLOYD FIRTH.

We note with deep regret the death of Mr. Samuel Lloyd Firth, the secretary of the Novelty Electric Co., of Philadelphia, at the early age of 23. He was the son of Mr. F. J. Firth, the secretary and treasurer of the Western & Erie Transportation Co., and was an amiable young man of great intelligence and high character, much esteemed by all who met him.

CONTENTS.

STORAGE BATTERIES AT NIAGARA.

THE great Niagara plant has scarcely yet been put to active work, but even at this early stage it may not be premature to discuss questions of the future involving the fullest economical utilization of this power. The thing above all others which gives the Niagara scheme its value is the permanency of water supply and its never-failing continuity. The flow of water goes on uninterruptedly day and night and in steady volume. It follows, therefore, that to operate only during 10 hours of the day would be utilizing less than one-half the power available with a corresponding non-utilization of the entire hydraulic and electric plant. It is hardly to be supposed that all the industries that will be attached to Niagara will be operated 24 hours per day, and hence the inquiry suggests itself whether some method of storing the energy during the night at the power station or at the factories may not prove economical. Without enumerating the methods which could be employed for this purpose under the conditions obtaining at Niagara, there is little room for doubt that electrical storage alone can fulfill the requirements. The storage battery must therefore be looked upon as probably the next adjunct to Niagara, and just in what manner it will reach its highest usefulness will much depend upon the nature of the industries to be transplanted to Niagara. What strengthens our belief in the adaptability of the storage battery for Niagara is the character of the enterprises already established there, and that of others which we know are sure to follow and which require the continuous current as an absolute necessity in the manufacture of their products, such as the aluminum of the Pittsburgh Reduction Co., and others which we might mention. At present such establishments require an equipment of reducing static transformers, and rotary converters to obtain the current suitable for their purposes. The question is a purely financial one and involves the consideration on the one hand of the cost of wheel pits, turbines, generators, static and rotary transformers, and, on the other hand, the rotary transformers and storage batteries of a capacity sufficient to store the energy of the machines required for the day load. The problem thus presented is a simple one. The addition of a storage battery at Niagara either at the main power house or at the points where the continuous current is required would thus fulfill the necessity of affording a proper utilization of available energy, and provide two sources and two kinds of current adapted to all purposes for which current can be utilized.

ELECTRIC LINES AND SHADE-TREES.

THE Supreme Court of Errors of Connecticut has handed down a decision, of which we give a summary in another column, which is of considerable importance to electric companies. It appears that upon the construction of an electric railway through the street of a village, the selectmen ordered the telephone company to remove their poles and wires to the opposite side of the street to make room for its overhead structure. In order to make a clear passage for the wires in the new location, the telephone company were compelled to cut the limbs of a number of shade-trees standing without the highway line, but having

branches extending over the highway. A suit for damages followed, resulting in a verdict for several hundred dollars in favor of the plaintiff, which was followed by an appeal to the Supreme Court. This court now decides that the cutting or mutilation of shade-trees by an electric company even when within the highway, is a tresspass upon the rights of the adjacent property-owner for which damages may be recovered, and that even the erection of poles and wires within the highway limits is an additional use of the right of way not included in the original taking of land for that purpose, and hence one for which, in the absence of express consent, additional compensation must be made to the adjacent proprietors As we understand the decision, the Court even goes so far as to intimate that the Legislature itself has no power to authorize the occupation of highways by electric lines without the consent of the adjacent owners, although statutory provision is made for the condemnation of a right of way when necessary by the county authorities. The telephone companies, especially in New England, have for some years been accustomed to place their lines for long distances upon private land by leasing or purchasing a right of way, and it is probable that this practice will become more and more common in the future, in view of the law of highway occupation as expounded in this and many similar decisions in other states. If a right of way must be paid for in any event, it is certainly preferable on every account to keep off the highway altogether in settled portions of the country. We have for many years advocated the purchase by the electric companies of adequate rights of way between prominent cities for the occupation of the vast numbers of wires which have now become a commercial necessity, and which have become a burden and an annoyance, both on the railways and on the highways. There would seem to be little doubt that the Connecticut and New Jersey view of the law will in time come to be the settled rule in all the other states, and in that case, some such plan will become an unavoidable necessity at no distant day.

OVERLAND MESSAGES TO EUROPE.

A breath of old-time industrial romance comes with the announcement that the Western Union Telegraph Company is making arrangements to retake possession of the old abandoned telegraph line, extending through British Columbia, started thirty years ago to run to Europe via Behring Straits and Siberia. This line was constructed as part of a great world circuit to connect Europe with America. The success of the Atlantic cable spoiled this plan. Now it is proposed to rebuild the old line and put Alaska in telegraphic touch with the world. The Indians long since took the wires and used them for making salmon nets. The plan was known to the last generation as the "Collins Overland Line to Europe." It was well supported. The Russian Government began the expensive construction of the 7000 miles of line from Moscow to the Pacific Coast; while loop lines into China and India were carefully laid out. In this country the Western Union Telegraph Co. raised and spent $3,000,000, which to-day is part of the watered capital that socialistic papers are so fond of prating about but which simply represents the courage of a number of modest folk with small savings. For thirty years, the investment has lain idle and dead, while of the work to which such men as William Orton, F. L. Pope, George Kennan and scores of others gave their best thought and hardest work nothing remains practically but the memory.

Now that the Russian Empire is so closely interested in the developments in Northern Pacific waters, there is no good reason to doubt that it will endeavor to meet the renovated Western Union line at the Behring Straits. The "Russian Extension" as it was once called will not offer very serious competition with the dozen Atlantic cables, but for strategic purposes it should have a high value. It may, perchance, have some interest for the Postal Telegraph and Canadian Pacific Telegraph Companies.

THE DOUBLE CARBON ARC LAMP.

One of the electrical patents which had thus far been sustained in its entirety, the Brush double-carbon lamp, has at last met with a reverse and after years of litigation involving it is said an expense to the Brush Company alone of over $200,000 is now declared not to be as broad as it has heretofore been held to be. Although Judge Showalter has been on the bench but a short while he has signalized his elevation to it by a number of strong decisions and that now rendered in this celebrated suit shows a grasp of technical details rarely met with in the legal profession. Judge Showalter holds that the Brush patent does not cover all forms of double carbon lamps, and while not invalidating the patent he leaves the way open to other devices not specifically covered by the Brush claims. In other words, he emphasizes the tendency of all the courts against upholding "broad" patents in all their breadth.

ELECTRIC CAR HEATERS.

THE New England Railroad Commissioners have taken up recently the question of heating the street cars in winter, and have begun hearings on the subject. Vice-President Cummings, of the Boston West End, has, we are glad to see, come out strongly for electricity before the Commission, remarking: "In every case, there should be electric heaters, for it is possible to heat the cars well with this new device." There is no doubt that the coming winter will witness a larger use than ever of electric heaters on street cars, but we are awaiting with some interest the action in regard to these devices, of the managers of the elevated and ex-steam roads. Obviously, trains on such lines can be admirably lighted and warmed electrically, if the companies are willing to go to the expense of installation and maintenance; and it would seem good policy thus to get rid at once of oil lamps and stoves or steam coils.

POLICE SIGNAL TELEGRAPHS.

THE NEW YORK POLICE BOARD wants a new signal system, and invites all interested in such to submit information about them. The system must provide a modern and complete telephone and signal communication between the station house and each part of the precinct.

Legal Notes.

THE BRUSH ELECTRIC CO. vs. THE WESTERN ELECTRIC CO.—THE WESTERN ELECTRIC DOUBLE CARBON LAMP DECLARED TO BE NON-INFRINGING.

On July 24 Judge Showalter, of the United States Circuit Court for the Northern District of Illinois, handed down a decision in two suits of the Brush Electric Co. against the Western Electric Co., for infringement of the Brush double carbon arc lamp patent No. 219,208, September 2, 1879.

The claims of the Brush patent are as follows:

1. In an electric lamp two or more pairs or sets of carbons, in combination with mechanism constructed to separate said pairs dissimultaneously or successively, substantially as and for the purpose specified.

2. In an electric lamp two or more pairs or sets of carbons, in combination with mechanism constructed to separate said pairs dissimultaneously or successively and establish the electric light between the members of but one pair, (to wit, the pair last separated) while the members of the remaining pair or pairs are maintained in a separate relation, substantially as shown.

3. In an electric lamp having more than one pair or set of carbons, the combination, with said carbon sets or pairs, of mechanism constructed to impart to them independent and dissimultaneous separating and feeding movements, whereby the electric light will be established between the members of but one of said pairs or sets at a time, while the members of the remaining pair or pairs are maintained in a separate relation, substantially as shown.

4. In a single electric lamp, two or more pairs or sets of carbons, all placed in circuit, so that when their members are in contact the current may pass freely through all said pairs alike, in combination with mechanism constructed to separate said pairs dissimultaneously or successively, substantially as and for the purpose shown.

5. In an electric lamp wherein more than one set or pair of carbons are employed the lifter D or its equivalent, moved by any suitable means, and constructed to act upon said carbon or carbon-holders dissimultaneously or successively, substantially as and for the purpose shown.

6. In an electric lamp wherein more than one pair or set of carbons are employed, a clamp, C, or its equivalent, for each said pair or set, said clamp C adapted to grasp and move said carbons or carbon-holders dissimultaneously or successively, substantially as and for the purpose shown.

The Western Electric Co. set up in defense the patents Nos. 418,758, 502,535, and 502,536 issued to C. E. Scribner and assigned to them.

After quoting from the specification of the Brush patent, describing the action of the lamp, Judge Showalter says:

"The ideas of the Brush invention in suit were apparently these: (1.) By separating the added pair of carbons first he threw the entire current down the other pair, and thus determined that the arc should form between said other pair, or pair last separated. (2). By separating the added pair at a greater distance apart than the other pair he avoided accidental alternation in the arc between the two pairs. (3). By permanently holding the added pair in such separated relation, the first pair could be fed together and consumed without stop.

"The observable interval between the point of time at which the separation between the added pair of carbons takes place and the point of time at which the separation of the other pair takes place the purpose being to determine the arc between the pair last separated—is the *dissimultaneousness* found in each of said six claims.

"With all respect for the learned writer of the opinion in the Toledo case and for the learned counsel for complainant, the formula of words 'dissimultaneous arc-forming separation,' does not carry any definite meaning. The adjectives *simultaneous* or *dissimultaneous*, are words of comparison. The former means that two or more occurrences or happenings are identical in time, the latter, that they are successive—that is to say, with an interval between each two in succession. The arc-forming separation which takes place between the first pair of carbons to burn, and the arc-forming separation which takes place several hours later between the added pair of carbons, are certainly successive and, loosely speaking, dissimultaneous, but these separations lack the unity or continuity of movement implied in the term *dissimultaneous* when used in this patent. As already said, Brush coined the word 'dissimultaneous' to express the momentary but observable interval—the slight but noticeable non-coincidence in time—between the separation of the added pair of carbons and the separation of the other pair in a unitary and continuous movement due to mechanism as invented by him and described in the patent in suit, in contrast with an apparently simultaneous separation due to any mechanism appropriate for the latter purpose.

"The patentee said further in his specification: 'I do not in any degree limit myself to any specific method or mechanism for lifting, moving, or separating the carbon points or their holders, so long as the peculiar functions and results hereinafter to be specified shall be accomplished.'

"The specification and claims were evidently prepared with the idea that *the mode of movement*, to wit, the rapid, successive and continuous separations between the pairs of carbons terminating in the arc between the pair last separated, could be secured to Brush, regardless of the mechanism by which this mode of movement should be produced. In *Brush Electric Company v. The Fort Wayne Electric Light Company*, Judge Gresham held, answering the contention that the first, second, third and fourth claims were for functions or results and hence, void, that mechanism such as described in the drawings and specifications or a substantial equivalent was an essential element in each of said claims. I am not called on to determine these constructions but the conclusion reached apparently in the Toledo case that no one of these claims contains the element of dissimultaneous or successive separations between the members of each pair of carbons for the purpose of forming the arc between the pair last separated, seems to me unsound. * * *

"Without going again over the mechanism, the lamp is constructed so that the carbons A shall first burn. By reason of the support K being carried on the upper carbon-holder of the first pair of carbons to burn, and of the greater distance between the two carbons of the added pair, said added pair could not be burned first. It is, in other words, the characteristic feature of this lamp, the very purpose signified by its construction, that the position of the first arc shall be determined before lighting as between the two pairs of carbons. Yet, in the opinion in the Toledo case this is declared to be 'a wholly immaterial and useless feature.'

"Even if it were, in fact, immaterial which pair of carbons burned first—supposing it to be true that if the carbons were separated simultaneously instead of dissimultaneously the lamp would still operate—the fact remains that the patentee took from the Government claims in which the dissimultaneous separations are the special feature. Moreover the feature of dissimultaneous arc-forming separations—referring here to the interval of hours between the arc-forming separation of the first pair to burn, and the arc-forming separation between the added pair,—is not in any one of the claims. In order to make out a case of infringement, the former element must be gotten out of, and the latter must be gotten into, each claim. This in my judgment cannot be done. The lamps made under patent No. 418,758 do not contain mechanism constructed to cause the dissimultaneous initial separations of the carbons, nor do the lamps made under patent No. 502,535, nor do the lamps made under patent No. 502,536. I hold, therefore, that no infringement is made out in either suit.

"The order will be in each case that the bill be dismissed for want of equity."

ELECTRIC LINES ON PUBLIC HIGHWAYS.—RIGHTS OF ABUTTING PROPERTY OWNERS.

The Supreme Court of Errors of Connecticut sitting at New Haven, handed down on June 24, a decision in the suit of Mrs. Caroline L. Bradley, of East Haven against the Southern New England Telephone Co., affirming the decision of the lower court. The plaintiff originally brought an action to recover damages from the defendant for cutting the branches of six shade-trees standing inside the plaintiff's premises without the highway limits. Two of the trees, it appears, were trimmed by defendant's agents entering upon plaintiff's premises. In the Superior Court it was shown, on behalf of the defendant that it was compelled by order of the selectmen of the town to remove its line to the opposite side of the highway from its original location, to make room for the conductors of an electric street-railway company; and hence it was contended that defendant was justified in doing such trimming of overhanging trees as was necessary for the proper operation of its line, and that such trimming was permitted and authorized by the selectmen. It was further contended that the branches overhanging the highway constituted a nuisance to the defendant as well as to the public, which the defendant had a right to abate. The court held that the defendant's acts complained of were prohibited by statute and were an illegal invasion of plaintiff's property rights. The jury found that the trees were not a nuisance and that unnecessary injury was done in their removal, and awarded the plaintiff $800 damages. An appeal was taken by the defendant to the Supreme Court of Errors. On appeal the plaintiff contended that the trees cut were not "upon the highway" and consequently not within the jurisdiction of the selectmen; that it was immaterial whether the cutting had been done from the inside or outside of the fence; that in the absence of a special statute the jurisdiction of the selectmen was limited to the making of the street safe for travel; that the defendant's acts were absolutely prohibited by statute, inasmuch as the erection of poles and wires imposes an additional servitude upon the land embraced within the right of way, for which compensation must be made to the adjacent owner; and inasmuch also, as the statute contains an express provision that no injury shall be done to any tree without consent of the adjoining owner; and finally that any act authorizing the cutting of trees without consent of the adjacent owner and without compensation would necessarily be unconstitutional and void. This has substantially been decided heretofore in cases in New York, New Jersey, Illinois and Maryland, to be the law. As above stated, the Court of last resort decided the plaintiff's points to be well taken, and confirms the award of damages given in the lower court.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 23, 1895.

Accumulators:—

Secondary Battery Plate, J. J. Rooney, Brooklyn, N. Y., 543,055. Filed Nov. 19, 1894.
A composite grid consisting of a perforated base plate and perforated coating plates.

Secondary Battery, E. Boettcher, Leipsic, Germany, 543,373. Filed May 12, 1890.
A battery containing a zinc oxide solution, a zinc cathode and a non-conducting covering that extends over the lower surface, the rim and the vertical stem of the cathode.

Alarms and Signals:—

Fire Alarm Box, J. T. Stack, Chicago, Ill., 543,063. Filed Jan. 3, 1894.
Consists in certain details of construction of a keyless box.

Registering Armor for Boxers, J. Donovan, Chicago, Ill., 543,086. Filed Dec. 19, 1894.
See THE ELECTRICAL ENGINEER, page 117, this issue.

Fire Alarm Box, C. A. Rolfe, Chicago, Ill., 543,103. Filed May 10, 1895.
An extensible hand portion normally confined within the casing and arranged to project therefrom when the frangible portion of the casing is broken.

Fire Alarm Box, C. A. Rolfe, Chicago, Ill., 543,104. Filed May 10, 1895.
A street or like fire alarm box, containing signal-transmitting means, with a telephone which can only be used by authorised persons.

Railway Signal, J. B. Stewart, Haverstraw, N. Y., 543,322. Filed Aug. 24, 1894.
A novel form of electro-magnetic clutch.

Distribution:—

Electric Transformer, J. A. Mosher, Chicago, Ill., 543,246. Filed May 7, 1895.
In a transformer, the combination with the primary coil, of a terminal block for carrying the terminals of the primary coil and of the main circuit, of a contact plug adapted to connect both ends of the circuit with the primary coil.

Testing Circuit for Alternating Current Systems of Distribution, H. C. Wirt, Schenectady, N. Y., 543,364. Filed April 23, 1895.
Means for testing transformer leakage in an alternating current system of distribution.

Dynamos and Motors:—

Dynamo Electric Machine, T. Hooker, Syracuse, N. Y., 543,081. Filed April 26, 1894.
A yoke having a coil is connected in series with the field magnets and polarized in such direction as to reinforce the entering horn of the field magnet and decrease the trailing horn of the same.

Alternating Electric Motor, J. A. G. Trudeau, Ottawa, Can., 543,233. Filed April 6, 1894.
Details of construction.

Dynamo Electric Machine, T. H. Hicks, Detroit, Mich., 543,383. Filed Jan. 13, 1894.

Electrometallurgy:—

Electro-depositing Device, J. Bossard, Dubuque, Iowa, 543,066. Filed Nov. 11, 1893.
The article to be deposited upon is caused to automatically travel through the bath.

Lamps and Appurtenances:—

Producing Pure Electric Light Carbon, E. G. Acheson, Monongahela City, Pa., 542,982. Fil d Aug. 25, 1894.
Consists in granulating coke, and subjecting it to the required degree of temperature necessary to volatilize the impurities associated with it.

Incandescent Lamp Socket, E. H. Heath, 543,016. Filed Mch. 21, 1895.

Carbon Holder, J. C. Knight, New York, 543,186. Filed Jan. 15, 1895.

Electric Arc Lamp, D. Higham, Boston, Mass., 543,243. Filed May 2, 1895.
Means whereby the normal lengths of the arcs of a twin lamp are maintained by the heat given out by the arcs.

Incandescent Electric Lamp, G. Westinghouse, Jr., Pittsburg, Pa., 543,280. Filed Aug. 29, 1893.
Details relating to a stopper lamp, which is supported in its socket without the use of intervening parts.

Electric Arc Lamp, H. J. Sage, Chicago, Ill., 543,355. Filed Feb. 18, 1895.
Details of construction.

Electric Arc Lamp, S. E. Nutting, Oak Park, Ill., 543,399. Filed Oct. 5, 1894.
The operating parts of the shunt have no direct connection with and are movable independent of the arc-drawing mechanism.

Electric Arc Lamp, W. Jandus, Cleveland, O., 543,445. Filed Dec. 19, 1894.
Surrounds the arc by an enclosed body of chemically inert gases, and surrounds such enclosure by an envelope or enclosed outer reservoir of chemically inert gases, said inner and outer enclosed bodies communicating with one another. (Has been shown in THE ELECTRICAL ENGINEER.)

Measurement:—

Meter for Alternating Electric Currents, L. Gutmann, Pittsburg, Pa., 543,039. Filed May 20, 1890.
In an electric meter, the combination with two or more stationary energizing coils, of an armature whose windings lie in different planes rigidly mounted on a shaft adapted to rotate and fans and a registering train for the purpose described.

Miscellaneous:—

Electrical Time-Annunciator, E. M. Edgerton, Chicago, Ill., 543,000. Filed Feb. 13, 1892.
Improvements upon the electric alarm clock, patented March 17, 1891. No. 448,836.

Electromedical Apparatus, J. R. Etter, Crawfordsville, Ind., 543,008. Filed June 19, 1893.
A portable electro-medical machine.

Electrically Controlled Voting Machine, C. A. Stitzer, Central City, Neb., 543,065. Filed Nov. 27, 1893.

Pneumatic-Transfer-Tube System, F. W. Jones, New York, 543,184. Filed April 15, 1895.
An electric circuit connects both stations with a switch for stopping, starting and reversing the air pump.

Process of Refining Sugar by Electrolysis, E. Javaux & C. F. Gallois, Paris, France, 543,249. Filed May 26, 1894.
Consists in adding lime in excess, to neutralize the acid constituents, precipitate the organic impurities, and prevent the formation of salts of lead, then treating the alkaline juice by an electric current.

Electric Registering Apparatus, A. Custodis, Dusseldorf, Germany, 543,336. Filed March 19, 1895.
Relates to an apparatus for electrically indicating at a distance the position of the pointer, scale-beam or other device.

Electric Clock-Winding Mechanism, L. H. Spellier, Philadelphia, Pa. 543,358. Filed May 28, 1891.

Railways and Appliances:

Trolley Wheel, C. Mitchell, Yonkers, N. Y., 543,048. Filed Dec. 20, 1894.
The contact is effected by means of balls and the trolley is provided with ball bearings.

Underground Trolley System, N. B. Ginocchio, New York, and H. C. Bridger, Woodridge, N. J., 543,130. Filed Dec. 27, 1894.
Involves an automatic switching system for throwing in successive sections as the car passes over them.

Electric Switch, J. W. Hearn, Brooklyn, N. Y., 543,181. Filed Oct. 3, 1893.
Relates to a track switch.

Trolley Stand and Pole, L. C. Seelye, Fort Edward, N. Y., 543,271. Filed Jan. 2, 1895.

Electric Brake, W. B. Potter, Schenectady, N. Y., 543,351. Filed March 28, 1895.
Means for operating brakes of trailers by means of an auxiliary generator upon the accidental separation of trailer from motor car.

Safety Appliance for Electric Cars, W. B. Potter, Schenectady, N. Y., 543,352. Fil d Apl. 9, 1895.
A controller equipped with a reversing switch having a certain additional series of contacts therein, by which the car is stopped in any emergency.

Electric Transportation System, R. E. Sherman, Chicago, Ill., 543,357. Filed Mch. 1, 1895.
A mail carrying receptacle is equipped with an electric motor suspended on an overhead track.

Electric Railway System, J. C. Henry, Westfield, N. J., 543,382. Filed May 13, 1895.
Consists in a three wire circuit fed by two generators of different constant potential, the line being divided into insulated sections, each of which is connected with that one of the generators which produces the potential suitable for that section. The rails of the track form the neutral conductor.

Means for Arresting Motion of Electric Cars, A. K. Bonta, Hoboken, N. J., 543,435. Filed Mch. 21, 1895.
A controller having one set of contacts establishing connections to send the car forward, another set to send the car backward, and the third set to reverse the relation of the field magnet and armature connections and establish a closed local circuit in which the terminals of the motor will be connected in series.

Switches, Cut-Outs, etc.:—

Electric Current Distributor, E. Thomson, Swampscott, Mass. and E. W. Rice, Jr., Lynn, Mass., 543,198. Filed April 24, 1884.
An electro magnetic cut-out device which is thrown into action by the melting of a fuse wire.

Electrical Switch, H. Stuebner, Philadelphia, Pa., 543,409. Filed Jan. 19, 1895.
Details relating to a push switch.

Telegraphs:—

Writing Telegraph, T. Ewing, Jr., Yonkers, N. Y., 543,231. Filed Jan. 9, 1894.
Relates to that class in which the movements of the transmitting pen in the plane of the paper are resolved into two components by attaching to the pen two bars placed at an angle.

Writing Telegraph, W. E. Gump, Brooklyn, N. Y., 543,241. Filed Feb. 24, 1894.
Means for connecting up the pulsator to line so as to send strong pulsations of the other polarity when the pen is moved in one direction, and means for reversing the polarities of the two sets of currents on reversal of direction of movement of the pen.

Writing Telegraph, J. H. Robertson, Brooklyn, N. Y., 543,495. Filed Jan. 9, 1894.
The fundamental telautographic operations of moving the pen and controlling its direction of movement, of lifting and lowering the pen, and of shifting the paper at the receiver, are effected by actual currents transmitted over the lines by the operation of the transmitter and not by a mere cessation of transmission of currents over either or both of the lines.

Writing Telegraph, J. H. Robertson, Brooklyn, N. Y., 543,496. Filed Dec. 19, 1894.
Details of construction relating to the above.

Writing Telegraph, J. H. Robertson, Brooklyn, N. Y., 543,497. Filed Mch. 21, 1895.
Details of construction.

Writing Telegraph, J. H. Robertson, Brooklyn, N. Y., 543,498. Filed. Mch. 21, 1895.
Details of construction.

Writing Telegraph, J. H. Robertson, Brooklyn, N. Y. 543,499. Filed Mch. 21, 1895.
Details of construction.

Telephones:—

Village Telephone System, C. E. Scribner, Chicago, Ill., 543,105. Filed Mch. July 2, 1886.
A subscriber may while signaling temporarily introduce his bell into the line of any other subscriber, said bell being automatically brought again into its own circuit after the signal has been sent so as to be in position to respond to any other call.

Telephone Exchange, W. J. Shibata, San Francisco, Cal., 543,106. Filed Oct. 11, 1894.
Details relating to an automatic exchange system.

Art of Telephoning, A. E. Paige, Philadelphia, Pa., 543,190. Filed Feb. 25, 1895.
See THE ELECTRICAL ENGINEER, page 118, this issue.

Telephone Transmitter, Z. E. Patrick, Chicago, Ill., 543,313. Filed Jan. 18, 1895.
A telephone transmitter, consisting of a hollow conical shell, and a body of variable resistance mounted rigidly upon the side walls of the cone.

Telephone Attachment, C. E. Bertels, Wilkes-Barre, Pa., 543,326. Filed March 20, 1895.
For holding the receiver.

THE GENERAL ELECTRIC CO. has received an order from the Michigan Central Railway Co. for two powerful search lights to be placed on Falls View Station terrace, with colored slides and lenses, in order to throw light upon the Falls after dark.

THE LAMB ELECTRIC CABLEWAY has been adopted for a 4-mile section of the Erie Canal, the work to be done this summer. The system has been fully described and illustrated in THE ELECTRICAL ENGINEER.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

D. P. PERRY ON THE OUTLOOK.

"The outlook for a golden harvest for the larger manufacturing companies was never better than it is to-day," says D. P. Perry, general manager of the Standard Electric company of Chicago. "The daily reports from our traveling men, local correspondents, and customers all comment on the bright outlook, and the cheerful and healthy tone pervading nearly every line of industry in nearly every community whether in the West or the South. Our correspondents lay especial stress on the plans that are being laid, or for work already contracted for, in the line of improvements and extensions by individuals and private corporations as well as public corporations. I do not recall a year in which so many and so large appropriations have been made for all municipal improvements of every character, from electric lighting plants to bridge building, and from street paving to extensions of water plants. Much of this is due not only to the improved commercial conditions that naturally follow a restoration of confidence, but also the prospects of abundant crops. Commercial travelers alone are not optimistic in this respect.

"Corporations are feeling the tonic effects of this cheerful condition and are agitating the question of the lack of economy in longer deferring certain public improvements. It is quite probable more than 100 towns now lighting their streets with oil or gas will own an electric lighting plant before the year closes."

ELECTRIC STORAGE BATTERY CO.

The Electric Storage Battery Co. reports increased business. Among the notable contracts made in last few days was one with the Anaconda Copper Mining Co. for a storage battery plant as auxiliary to their trolley system; another with the Western Union Telegraph Co. for their Washington, D. C., station; and a third to the U. S. Government for a plant at Fortress Monroe.

PORTLAND, ME., ELECTRIC WORKS.

Mr. John W. Upp, late of the General Electric Company, formerly superintendent of the Giant Motor Company, has accepted the position of superintendent and general manager of the Portland, Me., Electric Works and has entered upon his duties. Mr. Upp goes to Portland with a very high reputation as an electrical engineer, and has had valuable experience as a business manager.

CHANGES AT JACKSONVILLE, FLA.

Engineer Chas. Patterson, for nine years past chief engineer at the Citizens' electric light works Jacksonville, Fla., will take charge of the new city plant. Mr. Patterson is an electrical engineer of ability, says the local *Metropolis*, and the Board of Public Works made a wise selection in appointing him to his present post.

Mr. Patterson is succeeded at the Citizens' works by Fred Bishop, a competent electrician, formerly with the Georgia Electric Light Company of Atlanta, but who has been in the employ of the above company for several months. Both Mr. Patterson and Mr. Bishop are the right men in the right places.

SOLID SHEET INDIA MICA SEGMENTS OF A. O. SCHOONMAKER.

We have received from A. O. Schoonmaker, 150 William St., New York, a sample sheet of their various makes of stamped mica for insulating commutator segments. The types vary considerably in shape, and include the standard Westinghouse, G. E. and other forms of commutators for both dynamos and railway motors. We also notice a sheet for insulating rheostats. If the mica furnished by Mr. Schoonmaker is all of the high quality of which the samples are composed, there ought to be little trouble to its users from burn outs in generators and motors.

TURNER BROS., ATLANTA, GA.

A new electrical firm has been formed in Atlanta, Ga., the members being William W. and Oscar C. Turner, sons of Hon. J. D. Turner.

Oscar C. Turner, who will be the general manager, has been connected with the Georgia Electric Light Company for some years, having been purchasing agent for that company, while Mr. Will. Turner, the other member of the firm, is the southern agent of C. S. Knowles, one of the largest electric supply houses in the country.

Turner Brothers propose to do electric construction of all kinds, especially electric light wiring and bell work, while they further intend to carry quite a large stock of electric supplies to furnish the trade of this section. The Georgia Electric Light Company having given up wiring, Turner Brothers have secured their foreman and men and will carry on this work in the same manner that it has hitherto been done by the electric company. Besides their construction work, they intend to carry in stock a large supply of electric goods of all kinds. They have many friends who wish them all success in this venture.

UNDERGROUND WIRES IN BOSTON.

Putting the electric wires of Boston underground has progressed so favorably that the commissioners say that instead of the five years allowed for the completion of the work, it will be done inside of three years. Boston had more than 75,000,000 feet of overhead wires, requiring 12,898 poles for their support. So far 610,000 feet of duct has been laid furnishing accommodation for 200,000 feet of cabled wire, and over 26,000,000 feet of wire for telegraphic, telephonic and electric signalling purposes have been laid.

DIXON'S GRAPHITE PIPE-JOINT COMPOUND.

Twelve or fifteen years ago this article was known under the name of "Smear Grease," and later was changed to "Pipe-Joint Grease." It really is not a grease, and as the name has caused some misunderstanding, the Dixon Company have decided to change it, and it hereafter will be known as "Dixon's Graphite Pipe Joint Compound." This compound, under one or the other of its several names, has been in the market for about twenty years. It is not only useful for joints, and all steam, gas and water piping, but is equally useful for smearing gaskets and flange-joints of meters, traps, and for bolts, screws, etc. In the mills, mines and factories of the Dixon Company, this compound has been used in preference to any other article. That the Company is not prejudiced in its favor is shown by the testimonials of its customers, among whom are manufacturers of steam and hot-air radiators and heating appliances, iron companies, machinists, engineers and contractors, railroad companies, gas companies, and general manufacturers.

The President of the Water and Lighting Department of Harrisburg, Pa., said: "I have long ago forbidden the use of white or red lead or anything but your Graphite Compound in this department. The result is that we have no more breaking of bolts or nuts on our street mains, valves, etc., or any trouble of that kind in or about our pumping plant. I think those plumbers or steam-fitters who persist in the use of white or red lead are doing so purely through ignorance, as nothing is so costly, not even carelessness."

This Graphite Pipe-Joint Compound is manufactured by the Joseph Dixon Crucible Company, Jersey City, N. J.

BALL ENGINES.

The new electric light plant for the city of Wells, Minn., is being installed by Claussen & Bonwell of St. Paul. A "Ball" engine, built by the Ball Engine Co., Erie, Pa., direct connected to General Electric dynamo, furnishes the light. The Suburban Traction Co., Orange, N. J., are installing a 150 H. P. "Ball" engine. The Herald Building, Baltimore, will have an electric light plant, consisting of "Ball" engine, direct connected to a General Electric dynamo.

BOUND VOLUMES OF "ELECTRICAL ENGINEERING LEAFLETS."

The Electrical Engineer is now publishing in bound volume, price $2 each, the three series, Elementary, Intermediate and Advanced, of Houston & Kennelly's "Electrical Engineering Leaflets," and will be glad to send copies to any address, postage free, on receipt of price. The books are highly appreciated. Mr. H. A. Arvidson of Vallejo, Cal., writes: "Received bound volume, Elementary grade. Am greatly pleased with the book. It exceeds my expectations. Will order the other two volumes soon."

YOU CAN'T ELECTROCUTE THIS PARSON.

The pastor of a New England Congregational Church having bought a fan motor, wrote thus to the makers:—"However incredible it may seem, I have touched and handled with my bare hands with impunity the naked wire through which was running over 40 volts. I add this because —— —— says you are like all the others; you cannot believe it possible. In about two weeks we will demonstrate it to you, and then I will preach you a little sermon from the text 'Oh ye of little faith. Wherefore did'st thou doubt?' And that is Scripture, too."

"SAVE US MUCH TROUBLE AND TIME."

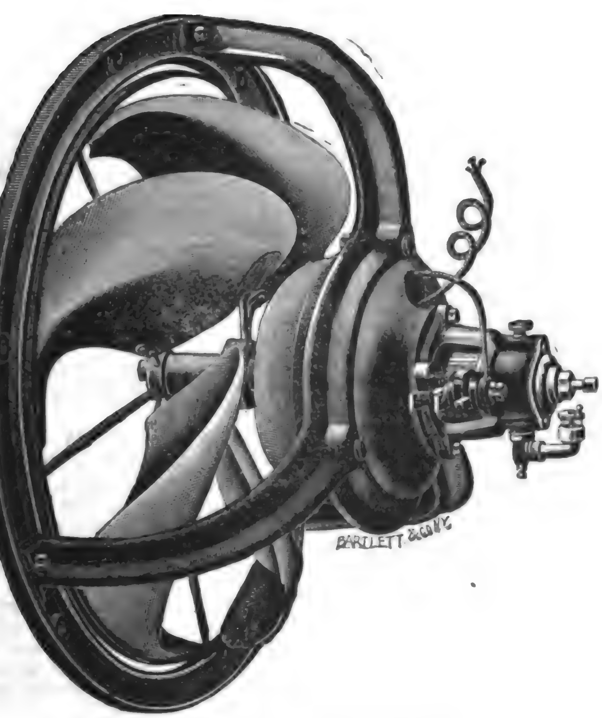
Mr. E. Carl Breithaupt, the consulting electrical engineer, of Berlin, Ont., writes us: "Please send me a morocco filing case for your Data Sheets. These sheets are an excellent idea and save us much trouble and time."

LUNDELL EXHAUST FAN OUTFITS OF THE INTERIOR CONDUIT AND INSULATION COMPANY.

The new circular of the Interior Conduit and Insulation Company, 527 West 34th St., N. Y., on their improved Lundell Exhaust Fan Outfits will be gladly received by the trade after the phenomenal record that the company has made in the sale of fans during this summer. During one of the hot spells, the daily orders were for 400 fans, and on one occasion they mounted up to 2,100 in four days, the record breaker being 1,400 in one day. In exhaust fan work the success of the company has been equally great, and this is unquestionably owing to the peculiar adaptability of the Lundell motor which is used in conjunction with it. The motor, being iron clad, is almost wholly inclosed and easily permits of connection by radial arms, spider, or bolts to any of the many forms of exhaust fans now to be found in the market.

Instead of the usual bearing in front as well as in the back of the fan, a shaft, which may be horizontal or vertical, is carried in two bearings in the motor frame itself, not supporting the shaft in any sense from the fan ring. This course insures perfect alignment and noiseless running.

All exhaust fan outfits are made with horizontal shafts, unless otherwise ordered, and are invariably made so that the direction of the flow of air is from the motor toward the fan. If it is desired to operate the fan with a vertical shaft or to drive the air through



LUNDELL EXHAUST FAN OUTFIT.

the fan and over the motor, it should be specifically stated in the order. With all standard horizontal shaft fans, an adjustable thrust bearing, as shown in cut, is provided. When the flow of air is desired contrary to the standard direction, a button and thrust bearing is placed at the rear of the motor.

In all horizontal shaft fans, lubrication is effected by oil. In vertical shaft fans, lubrication is effected in an oil receptacle enclosing a step at the bottom of the shaft, and a graphite or other self-lubricating bearing (never a grease cup or oil bearing) at the upper end of the shaft.

CREOSOTED WOOD CONDUITS.—The Michigan Pipe Co. of Bay City, Mich., issue a very interesting and instructive pamphlet, under the above title with regard to their creosoted wood conduits for all classes of electric service. It deals with the subject under all its various heads, and enumerates a number of undoubted advantages possessed by this useful and economical form of conduit, now being so largely adopted in these days of subway work.

THE AMERICAN REFLECTOR & LIGHTING CO. of 271-3 Franklin street, Chicago, have issued a very neat and useful little pamphlet of their "Paragon Reflectors" and kindred specialties. A great many excellent appliances are shown for service in connection with incandescent lamps for interior and exterior work. There are also stage dimmers, theatrical lamps, "incandescent calciums," clusters, &c.

C. C. SHELLEY & SON.

The announcement is made by Mr. C. C. Shelley that he has admitted to partnership his son Charles C. Shelley, Jr., and that the style of the firm will now be as above. The event is of more than usual interest. The house was founded as far back as 1854, and is therefore one of the oldest printing and publishing concerns in New York. It has done a high class of business from the start, including magazine work with De Vinne, and the bulk of the printing and blank book making for some of the largest insurance and drug houses in America. It has also had the patronage of many electrical concerns, including the General Electric, the telephone companies, the cable companies, etc. It has printed THE ELECTRICAL ENGINEER continuously since its first issue in 1882. Among its book publications—which include also a large quantity of religious literature—may be mentioned Foster's "Central Station Bookkeeping"; Noll's "How to Wire Buildings"; and Martin & Sachs' "Electrical Boats and Navigation." The new partner in the firm is a practical printer and publisher, having already spent several years with his father. The firm announces an increase in facilities and an installation of new machinery. It is worthy of mention that Mr. Shelley, senior, was one of the first printers in New York to recognize the advantages of electric power, and that THE ELECTRICAL ENGINEER, as well as all the other press work in the establishment at 66 Park Place, has for years been done by electric motor.

AN APPLICATION OF ELECTRICITY TO THE BLEACHING OF OILS AND FATS.

IT has recently been claimed that oils and fats may not only be bleached, but sweetened and purified generally by treating them with an electric current. The system upon which this is effected is as follows:—There is a tank divided into two parts by means of a porous partition; in one of the compartments thus formed is placed a solution of common salt at 8° Twaddell strength, and immersed in this solution is a carbon electrode. In the other compartment there is a mixture of the oil or fat with a similar salt solution, and immersed in the mixture is a copper electrode. A continuous electric current is then generated by means of a dynamo, the oil and salt solution being agitated by mechanical means at the same time.

APPROPRIATION FOR MUNICIPAL ELECTRIC LIGHT PLANT.

The following is a digest of the opinion of the court in *Christensen* v. *City of Fremont* (63 N. W. Rep. 364).

1. The power conferred upon cities of the second class, having over 5,000 inhabitants, to provide for and regulate the lighting of the streets implies the power to erect and maintain an electric lighting system for that purpose.

2. From the power to provide for and regulate the lighting of streets, however, no power can be implied to erect or maintain a lighting system for the purpose of supplying light to private buildings.

3. The latter power is conferred upon such cities by Sess. Laws, 1889, c. 19.

4. That an act providing for the levy of a tax and the issuing of bonds for erecting and maintaining a lighting system provided how money must be raised for the purpose when it is not already available; but where a city already has in its general fund sufficient unappropriated funds it may appropriate and use the funds for the purpose of erecting a lighting system.

5. A city of the second class, having more than 5,000 inhabitants, may make special appropriations for improvements at other times in other ordinances than the annual appropriations bill, provided such appropriation first received the sanction of the majority of electors either by petition or at an election.

NEW YORK NOTES.

THE NASSAU COMPANY in Brooklyn has at last been permitted to put its trolley system into operation. One can ride to Canarsie for five cents.

GENERAL ELECTRIC ACTIVITY.—Vice-President Ord states that the General Electric Co. now has 4,400 men at Schenectady, with a weekly pay-roll of $45,000,—900 men at Harrison, N. J., and 2,000 men at Lynn.

THE NATIONAL CONDUIT MFG. CO. of the Times Building, New York, have issued a large and very handsome pamphlet. It contains a view of their factory at Hastings-on-Hudson, a technical description of their work and methods, and a fine series of half-tone cuts illustrative of their installations for different classes of work in all parts of the country. Some of these pictures, by the way, give an admirable idea of the difficulties encountered in laying down a subway system.

CANADIAN NEWS.

MR. ROBERT ANDERSON, electrical engineer, of Ottawa, is installing a plant of 600 incandescent lights at Van Kleek Hill, Ont., for Col. Wm. Higginson. Mr. Anderson is also installing a 100 lt. electric plant for the Geo. Matthews Co., Ltd., for their pork packing establishment at Hull, Que. Mr. Anderson recently placed the following motors, viz.: one 5 H. P. motor for Ottawa Plating Works, one 1 H. P. motor for the Carling Brewing Co., one ½ H. P. motor for O. Robert, one 1 H. P. motor for Ratterton & Bro., one 1 H. P. motor for Fotheringham & Popham, stationers.

NEW ENGLAND NOTES.

THE SIEMENS & HALSKE ELECTRIC CO., of America, have removed their New England Office to the Equitable Building, Boston. Henry C. Radford is manager.

THE OLD COLONY-SHAWMUT STEAM ROAD is looked upon as probably the next in the vicinity of Boston to be electrified. It is a short line and devoted almost exclusively to suburban passenger traffic.

MR. HENRY SACHS (late Kaliske) has now opened an office at Room 20 A, Equitable Building, Boston, as a broker in notes, stocks and bonds, and will be glad to handle the business in these lines of any of his friends. His acquaintance with the electrical trades, through his former connection with the Beacon Company, should render him a good financial intermediary in such lines.

PHILADELPHIA NOTES.

500 IN PENNSYLVANIA.—There are no fewer than 500 street railway companies chartered in the State of Pennsylvania. Some day they may all be running. Eight years ago there were only 60 such corporations in the State.

THE EASTERN ELECTRIC CO., whose non-infringing telephone switchboard is illustrated and described in this issue, have secured an order for a 400 subscriber board. This order was given, it is said, after a thorough examination of all boards on the market.

MR. L. H. MCINTIRE has resigned as general manager and engineer of the People's Traction Co. of Philadelphia and has been succeeded by Mr. Beetem, who is also a well-known electric railway expert.

SUSQUEHANNA, PA.—Arrangements are being made to construct a three-mile electric road between Susquehanna and Lanesboro. A. W. Cook, secretary of the Susquehanna Elec. Lt. Ht. & Pr. Co., has the matter in charge, and as soon as the estimates are completed will proceed to organize the company.

MR. JAMES MURTLAND, who for some four years past has been the secretary of the Pennsylvania Electric Engineering Co., of Philadelphia, has resigned and has now established himself in business at 918 Betz Building, where he will devote himself to the handling of electrical specialties, more particularly in the field of light and power. He will also represent the "Rival" Oil purifier, which is in use in a great many plants with marked success.

WESTERN NOTES.

THE WESTERN TELEPHONE CONSTRUCTION CO. report the sale of 100 telephones at Wapakoneta, O.

THOS. G. GRIER, of Grier Brothers, Western Managers of the Bryant Electric Company, has just returned from a six days' bicycle trip through the southern part of Wisconsin.

ST. LOUIS, MO.—It is stated that negotiations are going on for the purchase of all the St. Louis street railways by English capital.

INDEPENDENCE, MO.—W. R. Whaley, formerly superintendent of the Citizens' Electric Light Company, has accepted a position with the Rapid Transit railway as an electrician.

CALIFORNIA.—Business is reported booming in California, and one of the reasons is said to be the increasing use of electric power in mining operations.

ST. LOUIS, MO.—The Interstate Complete Electric Construction Company of 818 South Seventh street, has confessed judgment to the United Electric Improvement Company in the sum of $7,763.

PARK CITY, UTAH.—The water in the Ontario mine has been converted from a burden into a blessing by means of running it into a drainage canal that discharges by flume over a Pelton wheel at a height of 120 feet. The wheel runs an alternating current dynamo of about 100 H. P. whose current is carried three miles to the company's works where it lights the mills, &c. and runs motors in the machine shops. The plant is to be enlarged. Only one man is needed to run it.

THE MILWAUKEE ELECTRIC MANUFACTURING COMPANY, with a capital stock of $8,000, has filed articles of incorporation. The incorporators are John E. McKivitt, Mathias Weisser, Joseph C. Schmitt and Henry W. Newton.

THE A. W. HARRIS OIL CO. whose main office and factory is located at Providence, R. I. have re-established their Chicago office at 1325 Monadnock Building. Mr. Urban W. Frink well and widely known in the West takes the management of their Western business in place of Mr. B. S. Terry, who now looks after the Eastern business.

APPLETON, WIS., is a great sufferer, in its industries, by the order of the U. S. Government totally suspending the use of water from the Fox River. Its electric lighting and street railway plants, which have heretofore depended upon the river for motive power, have been seriously crippled and have had to order steam equipment.

C. E. WOODS & COMPANY, a firm which consists of Clinton E. Woods and Charles E. Corrigan, have reorganized their business into a corporation under the firm name of C. E. Woods Company, with a capital stock of $100,000, their purpose in doing so being to take up a class of heavy electrical engineering in all parts of the world; and they are now making detailed arrangements to open offices in New York, San Francisco and Tokio, Japan. Their principal business will be the designing of heavy electrical apparatus and equipment, by Mr. Woods. This concern now has contracts with three manufacturing companies to design all of their apparatus, and act as consulting engineers, besides much miscellaneous work in general engineering.

NEW YORK NOTES.

H. B. COHO & CO. have notified the trade that they have become the New York agents for the Eddy Electric Mfg. Co. During the past twelve months they have installed over 5,000 H. P. of motors and generators.

SYRACUSE, N. Y.—The Syracuse Storage Battery Co. have furnished an outfit for the store of Dey Bros. & Co., to supplement the isolated plant which shuts down at 6 p. m. The installation was made by the Electrical Engineering & Supply Co.

THE INTERIOR CONDUIT & INSULATION CO. have issued a neat descriptive and illustrated circular with reference to their new generators for gas engine service recently brought to notice in the ENGINEER. The sizes range from 8 h. p. up to 45 h. p., the voltage being from 115 to 150.

NEW YORK CITY.—It is understood that the Westinghouse (Wheless) underground system is to be adopted on the Eighth avenue line. The method was recently described in THE ELECTRICAL ENGINEER, and is of the sectional class, the track only being "live" as the car passes from contact to contact.

MR. FRANK S. DE RONDE, general sales agent of the Standard Paint Co. said last week: "Our goods are still keeping to the front, and we are selling more "P. & B." than ever. Their sale is rapidly increasing in all parts of the world, and we are daily in receipt of orders not only from our old customers but from many new ones. Our references are the many customers who have dealt with us for the past ten years. From present indications, we anticipate doing a very large business in the Fall."

J. L. SOMOFF, 11 Park Row, has issued a neat catalogue of his miniature incandescent lamps, of which he has so long and so successfully made a specialty. Mr. Somoff has wonderful taste and ingenuity in this line, and many of his lamps are marvels of beauty or of oddity. In these respects, he well deserves to be called the American Trouvé. He does not confine his attention, however, to decorative small lamps, but makes them for physicians and dentists, and for many useful purposes in the arts and sciences. His prices are reasonable, and he is quick to embody and carry out any new idea or suggestion.

MR. J. W. GODFREY, of the India Rubber & Gutta Percha Insulating Co., accompanied by his nephew, Mr. R. J. Simes, Jr., son of the auditor of the New York *Herald*, and a member of the business staff of THE ELECTRICAL ENGINEER, left for Europe on July 24, on the "City of New York." Mr. Godfrey's departure was signalized by a little banquet at Mouquin's on the preceding Monday, and by a private dinner party given by Dr. Habirshaw at Delmonico's on Tuesday; while numerous evidences of esteem were sent on board the steamship before she sailed. Mr. Godfrey expects to join his wife and daughters in Paris, and will make a run through France, Switzerland, Germany and England before his return in September.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XX. AUGUST 7, 1895. No. 379.

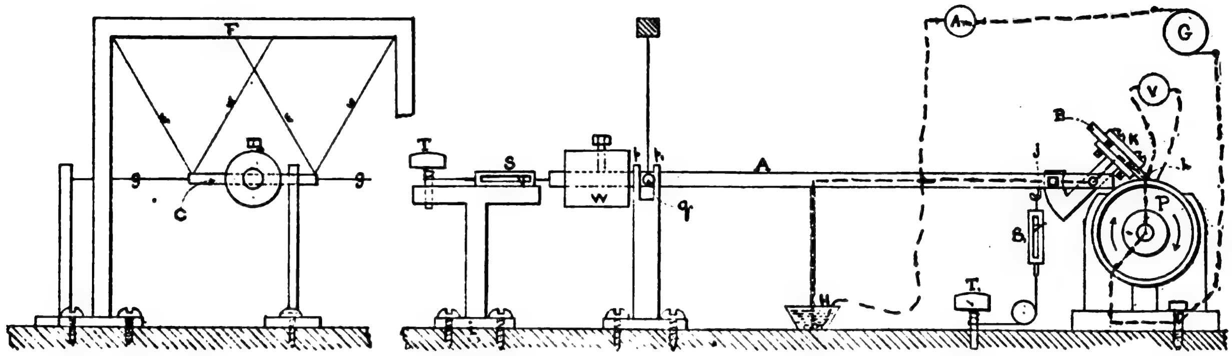


FIG. 1.—DIAGRAM OF APPARATUS FOR TESTING BRUSH FRICTION ON COMMUTATOR.

THE RELATIONS BETWEEN PRESSURE, ELECTRICAL RESISTANCE AND FRICTION IN BRUSH CONTACT.[1]

BY E. V. COX AND H. W. BUCK.

LITTLE or no information is available concerning the relations existing between the three fundamental quantities involved in the brush contact of electrical machinery, and the lost power resulting from poor adjustment of the brushes. The following investigation was, therefore, undertaken with the object of furnishing some accurate data on this subject. Those engaged in the management of dynamos and motors, while carefully attending to most of the details, apparently decide at what pressure the brushes shall be used more from common experience and guess-work than from any knowledge of a scientific nature.

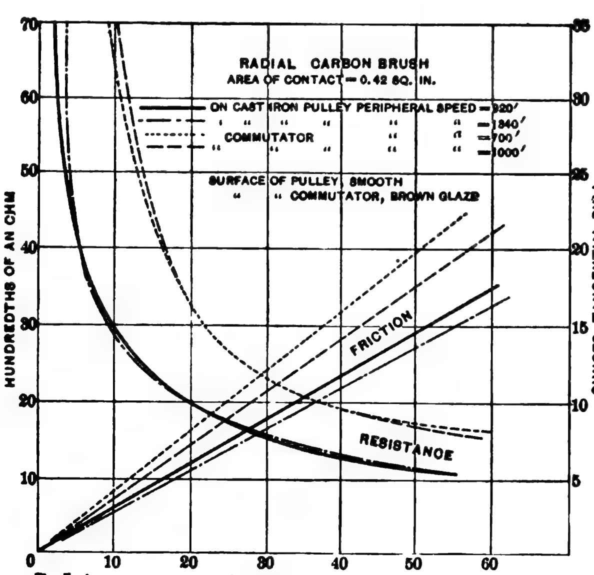

FIG. 2.

The method adopted in making this investigation can best be explained by reference to the accompanying diagram, Fig. 1. The electrical resistance of the brush contact on the various surfaces employed, was determined by the fall of potential method, using a Weston ammeter and millivoltmeter. The normal pressure of the brush on the cylindrical surface upon which it was sliding and the tangential pull due to the resulting friction were measured by delicate spring balances.

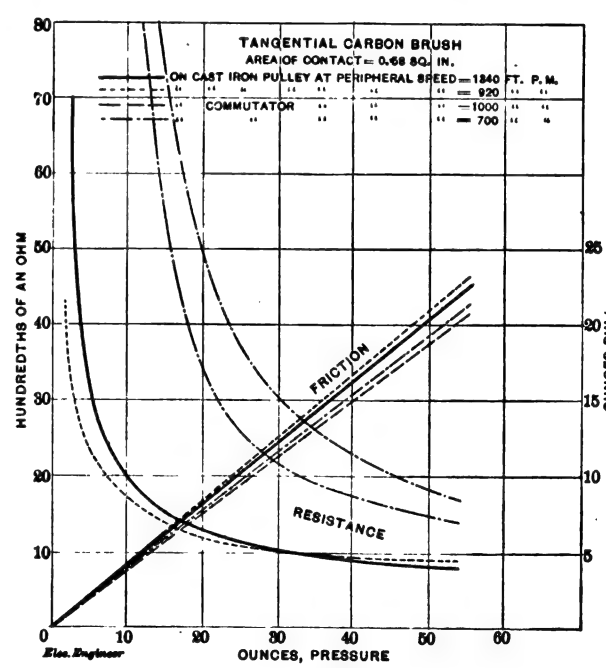

FIG. 3.

In the diagram, P represents the position of the various commutators and other cylinders experimented upon, which were mounted upon the shaft of a one horse power motor, where the pulley is ordinarily placed. The cylinder was thus caused to revolve, giving a sliding contact to the brush, similar to that existing in ordinary practice.

The brush B was carried in the holder K which was connected to the lever arm A by a swivel so that the brush could be placed at any desired angle with respect to the

1. Electrical Engineering Thesis, Columbia College, New York.

surface. The arm A was suspended at the point q by means of the cross bar C and the four wires w, w, from a rectangular frame work F which was fastened to the floor. This arrangement enabled longitudinal motion of the arm to take place with minimum friction, and at the same time effectually prevented all twisting of the brush through rotation of the arm about its axis. To prevent the brush from moving laterally on the surface of the contact cylinder, two guys G, G, were placed horizontally on either side of the arm A. The scale S and thumb-screw T were used to produce the various pressures on the brush; the lengths of the lever arms $q\,j$ and $q\,h$ being considered in calculating the actual pressure on the cylinder. To balance the weight of the arm A and attachments, the weight W was placed on the arm and adjusted until there was no pressure on the brush. By means of the thumb-screw T the pressure could therefore be varied from zero to any desired number of pounds. The two pins p and p_1, on either side of the cross-bar C, limited the longitudinal motion of the arm A to a tenth of an inch. They were so adjusted that with zero pressure on the brush the cross bar just touched the pin p_1. When pressure was applied to the brush, a tangential pull resulted, due to the friction between the brush and the revolving cylinder. The pin p_1 prevented

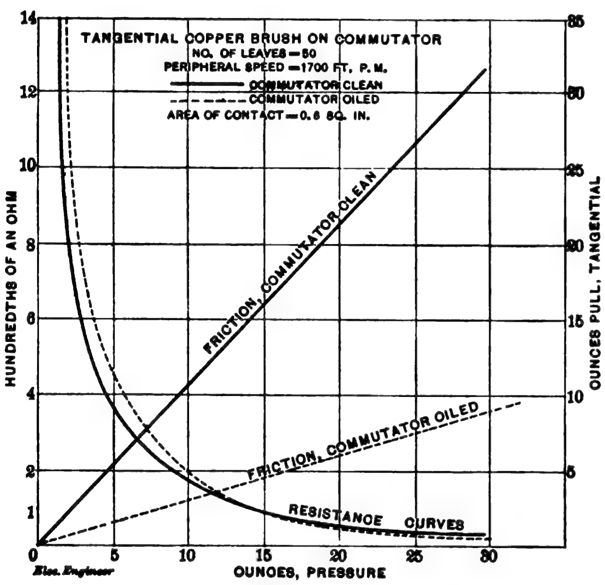

FIG. 4.

this pull from displacing the brush. The force just necessary to draw back the bar C from the pin p_1, was the value of this tangential pull and was measured by means of the scale S and thumb-screw T.

The electrical resistance of the brush contact was found by the fall of potential method as follows: the current through the brush, measured by an ammeter A m was furnished by the generator G, the circuit being completed as shown by the dotted line in the diagram, H being a mercury contact. The drop between the brass brush holder, which was one quarter of an inch from the point of contact, and the revolving cylinder, was given by a voltmeter V.

The accompanying curves represent the simultaneous relations existing between the normal pressure of the brush on the cylinder, the electrical resistance of contact and the tangential pull due to friction, abscissae measuring pressure in ounces and ordinates resistance in ohms, and in the case of the friction curves the pull in ounces. Each curve is plotted from the average of four curves taken under similar conditions; the curves agreeing within a few per cent. and each of which was obtained from ten observations taken between zero and four pounds pressure; hence the curves shown are each the result of forty observations. Fig. 2 shows a comparison between the resistances of a radial carbon brush on a cast iron pulley and on a commutator, the diameter of the commutator being 3 inches and that of the cast iron pulley 3.6 inches. Fig. 3 shows the same comparison for a tangential

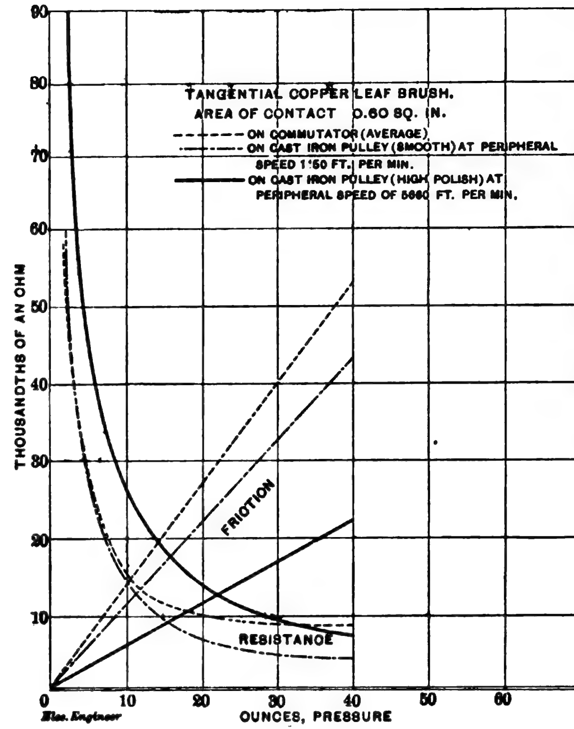

FIG. 5.

carbon brush. Fig. 4 shows the result of oiling the 3-inch commutator when a tangential copper brush is used. Fig. 5 shows the comparative resistance of a tangential copper leaf brush on a commutator and on two cast iron pulleys of different diameters. The diameter of the commutator was 3 inches; that of one cast iron pulley

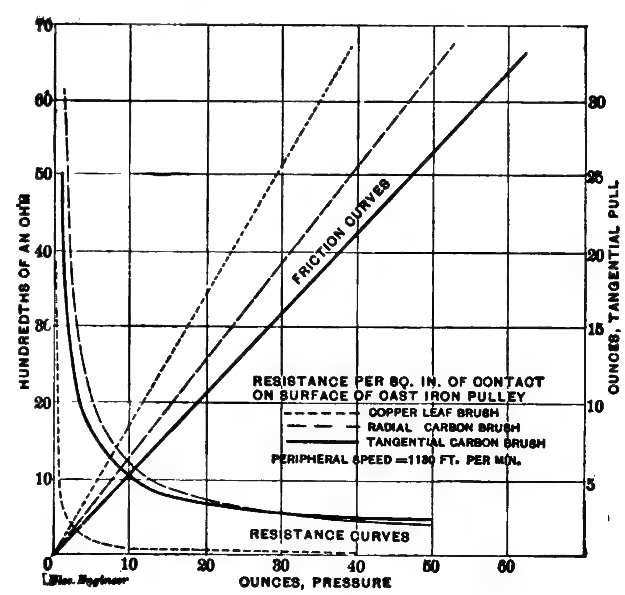

FIG. 6.

was 3.6 in. and that of the other 10 in. Fig. 6 shows the resistance per square inch of contact for three different brushes on the same cast iron pulley the diameter of which was 3.6 inches. Fig. 7 shows the same comparison when a three inch commutator is used. From these curves, the following conclusions can be derived:

1. The resistance of the brush contact does not vary

inversely as the pressure, for beyond a certain point a great increase in pressure produces only a slight diminution in resistance.

2. The critical point in the various resistance curves occurs at different pressures for different brushes.

3. The contact resistance of carbon is much higher than that of copper.

4. The contact resistance of all brushes is less on a cast iron pulley than on a copper commutator.

5. Slightly oiling the cylindrical surface only slightly increases the contact resistance.

6. The tangential pull due to friction is directly proportional to the pressure on the brush.

7. Slightly oiling the cylindrical surface greatly diminishes the friction.

8. For the same brush the friction is less on cast-iron pulley than on a copper commutator.

9. The friction of a copper brush is greater than that of a carbon brush at the same pressure.

10. The friction of a radial carbon brush is greater than that of a tangential carbon brush at the same pressure.

11. The friction of all brushes is slightly less at high than at low peripheral speeds.

The most advantageous pressure at which to work any

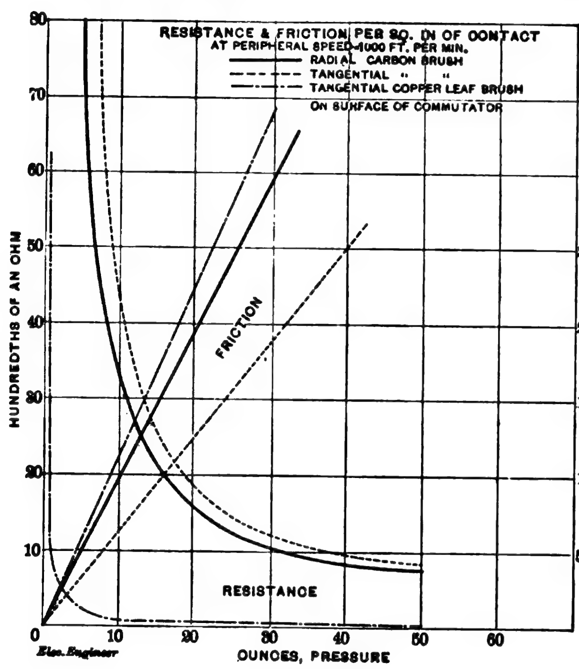

FIG. 7.

given brush will depend largely upon the relations existing at the different pressures between the loss of electrical energy due to ohmic resistance and the mechanical work consumed by the friction of the brush. The former can be found in watts for any point on one of the resistance curves by multiplying the resistance given for that point by the square of the current passing through the brush; and the latter, in horse-power, by multiplying the tangential pull in pounds, due to the friction of the brush, by the peripheral speed in feet per minute and dividing this product by 33,000.

For instance, in Fig. 7, take the resistance of the radial carbon brush at 24 ounces ($1\frac{1}{2}$ lbs.) pressure and assume that 20 amperes are passing through it. The ohmic resistance at this point is .13 ohm which multiplied by 20^2 gives 52 watts $=$ .07 H. P. At this same pressure the tangential pull is found to be 23.5 ounces $=$ 1.47 pounds. This, multiplied by the peripheral speed, 1,000 feet per minute, and divided by 33,000, gives .042 H. P. as the mechanical power lost in friction, being in this case about two-thirds of the electrical loss.

MY EXPERIENCE WITH INTERIOR WORK.

BY

A. E. Dobbs

CONDUIT work, at one time expected to supersede all other forms of wiring, has not in all respects fulfilled the conditions exacted of it. It has led to many improvements in wiring and also to the introduction of some methods that are not at all desirable.

When Mr. E. H. Johnson first introduced his system, he, as a practical man, elaborated it even to very small details under the supposition that his plans would be carried out; which, unfortunately, they were not. The first fault to be found was with the tube itself. It was not strong enough or flexible enough to stand all the rough usage to which it would naturally be subjected. Neither was it waterproof when exposed to dampness. The original single tube system was soon frowned upon by the Fire Underwriters and the double tube system had to be substituted, doubling the cost all round. Then while the price of the tube itself was reasonable enough, the cost of the fittings, elbows, junction boxes, etc., was enough to make a contractor stop and think. Result,—a discarding of most of the fittings and the adoption of the loop system.

Now the weak spots in all wiring systems are the outlets, both as to insulation and resistance. In all my experience I have known but few cases of trouble upon the lines. It has nearly always been either at the outlets or in places where wires were bunched to reach the outlets; and in loop wiring we have four wires to deal with where we formerly had two. The ends of the conduit chafe the wires, if nothing worse, and it often happens that four ends are difficult to dispose of. Again, in moulding or concealed work you could always depend upon finding the joints soldered

In the loop system the ends are not always soldered together by any means. The ends are left hanging until the plasterers get through. Then along comes the fixture man who cuts them off to suit himself and proceeds to connect up his fixtures. He will not solder the connections; that, he contends, being the wireman's work. The wireman throws the responsibility on the fixture man with the result that it is not done at all and the inspector is so anxious to boom conduit work that he never seems to look at the outlets. Thus we see that the loop system may not only greatly increase the distance between some lamps and the centre of distribution, but that bad joints may cause quite a perceptible falling off in candle power in the more distant groups of lamps.

But in spite of all this, the conduit system proved a good thing. It protected the rubber insulation of the wire in a great measure from the surrounding air, insuring longer life. The tube itself was a good insulator under all ordinary conditions, thus affording double protection against leaks; and lastly mice and vermin let it alone, an important point where rubber insulation is insisted upon.

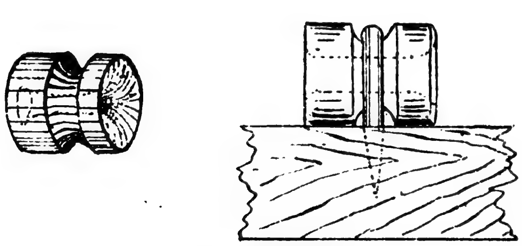
Of course the Interior Conduit & Insulation Co. soon had rivals in their particular field, and we quickly had several kinds of tube, among which Vulca, and the American Circular Loom have become the most prominent. Vulca tubing is a good insulator, an excellent substitute for hard rubber, and is not apparently affected by dampness, but it is so very brittle that it has to be handled with great care, and its low cost is offset by the extra time and care required in handling it. If a piece falls on the floor it breaks. A contractor must, therefore, buy considerably more than he actually needs, and if after the conduit is in place a piece should become broken, as often happens, is that piece taken down and replaced? Well, hardly; that would often mean taking down a hundred feet of conduit.

It is said that mice sometimes attack this tubing but I have never seen a case of that kind. It is easy to fish

through, having a hard smooth surface on the inside. But there is not a great deal of fishing done in conduit work. Fishing is impracticable in a great many cases owing to the length of the lines, numerous angles, etc.; besides, men who take contracts are not willing to do two or three days' extra work, to say nothing of the fact that larger tubing would be required, adding still more to the expense, the original idea of using a single tube and very thin insulation having to be abandoned. Specifications and rules calling for fished work are calmly ignored and plasterers find the wires hanging in their way as they did in the days before conduit was brought out. The Fire Underwriters are largely responsible for this in forbidding the use of strings for drawing in the wires. Doubtless they wanted to make sure of a continuous conduit, but I cannot see how they are any more sure of it under the present methods. And as to pulling wires out and renewing them without breaking the tubing; well it *may* be done *in some cases.*

So much for plain unarmored conduits. Almost simultaneously came "brass armored" and American Circular Loom conduits. There was not the least doubt about the brass armored conduit being a decided improvement over all previous kinds. But the Underwriters still objected to the single tube, twin wire system, so that while the cost was greatly increased, the contractor received but a small portion of it for his work. Moisture would get into it when the walls were freshly plastered and seemed unable to get out again; and I have seen conduit taken from damp places that was almost pulpy from moisture. Then men will not always take time to crimp the joints; besides in many cases it is very troublesome to do so. There is no use in arguing what the system would do if properly installed. The most specific directions and lectures as to the proper mode of installation will not help a careless wireman or alter the financial aspects of the case to the contractor who has been compelled to "figure close" and who tries to save all he can on the labor account.

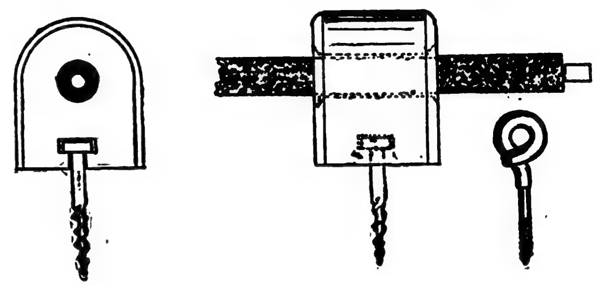
The American Circular Loom sprang into popularity among contractors and insurance men alike from its toughness, flexibility and ease of installation. There are no extras, such as elbows, sleeves, or junction boxes, no special tools to buy and weight down the tool bag; its inside surface is smooth, making it easy to push wire into it; if crushed, it can be straightened out. A wireman can run three or four hundred feet of it while getting ready to run any other kind; so that notwithstanding its comparatively high price it is found for small installations at least to be as cheap as, if not cheaper than, any other. Of course it would not do in very damp places and where you had to look out for cement, but that seems the only objection



FIGS. 1 AND 2.

to it. Both "brass armored" and "Circular Loom" conduits had their partisans among engineers, contractors and inspectors.

The Interior Conduit people, however settled the matter by bringing out their now famous iron armored conduit, which is undoubtedly the best thing yet in conduit work. As this conduit can be installed on the single tube plan the cost of material is but slightly more than the brass armored or flexible. The cost of labor will be somewhat greater, and the wireman has to buy about twenty-five dollars' worth of tools to get started in this kind of work. Another tube lately brought out consists of flexible hard rubber sheathed by lead armor, thus protecting it from the air and dampness. It seems to me almost as flexible as the Circular Loom and possesses the advantage of being moisture proof; the inside is as smooth and hard as Vulca making wiring easy. The price is about the same as the Circular Loom. The Underwriters, however, have never to my knowledge, endorsed it, though I cannot see why not. Still I have never had any experience with it, and it may develop faults not apparent from an examination of samples. I should think it would have to



FIGS. 3, 4 AND 5.

be handled with considerable care, and it might be easily crushed.

Now for another system or rather a modification of an old system. Outside of our largest cities the majority of houses in this country are built of wood, or at least with lath and plaster walls so constructed as to leave plenty of space inside the lath for wires, and the demand in such houses is for cheap and safe wiring. As to wire. If one can get the local inspector to agree to it, what is commonly known as weather proof wire triple braided can be used. While this wire will not stand the laboratory tests of rubber insulated wire, it will last longer in dry places. I have seen so much rubber wire get hard and crack after four or five years' use that I have very little confidence in it for this class of work; while I have seen "K K" wire exposed for years to the trying conditions of overhead work in New York city apparently as good as ever, except that the outside braid showed some effects of the weather.

In ordinary cases wires are not called upon to meet the tests laid down by the Board of Underwriters. They do not have to carry current under water; they do not get soaked in lime water, and they do not carry 500 volts. On the contrary they are generally so run that if the wire were bare it would still be safe and it is well to remember that mice let all asphaltum compounds alone. When threading between joists and partitions, I generally use the ordinary porcelain circuit breakers and staple, or tie them to the joists or studding, Figs. 1 and 2, and draw the wires through from outlet to outlet as in the conduit system. When going through joists I use porcelain bushings; they are nearly as cheap as any other, and I have them large enough for the wire to pull through easily or if there is a long run one can use flexible conduit tied to the ceiling between the lath and avoid boring holes. At the outlets I use porcelain tubes with at least a ⅜ inch hole and pull both wires belonging to the same loop through one tube; this prevents the wires getting mixed and saves testing everything to match the ends. In case any other tube is used for the outlet than porcelain, such as Vulca or hard rubber tubes, at least ½ inch in size should be used.

Figs. 3 and 4 show an insulation which would be good for this kind of work and which ought to be sold for about $30 per thousand. It is made of porcelain with a screw in the bottom which may be moulded in the insulator or afterwards set in with lead. I have never seen exactly such an insulator on the market; it probably is not manufactured, and manufacturers are welcome to the idea. The

nearest approach to it is the Fletcher insulators which are made in several parts, are not so strong, are high priced and not nearly as good. Another resembles it in having a hole in the top but it takes two screws in the base. Fig. 5 shows the Seely pigtail insulator which would be simple, cheap and good if the insulation could be made of porcelain instead of hard rubber. Mr. Seely is welcome to this suggestion also. Both insulators Figs. 3 and 5 could be turned in by hand and thus lighten the burden of profanity upon the wireman who has to work a ten inch screw driver in a six inch space.

A job of this kind will satisfy customers, satisfy the inspectors, and enable one to make some money on the contract. And, where a regular conduit job is called for, one should work in iron armored conduit if one can; if not, the flexible kind is to be preferred.

ROUNDABOUT NOTES IN ELECTRICAL EUROPE.—I.

STREET CAR TRAVEL IN ANTWERP.

BY

E. J. Wessels.

It is a surprise to find that electricity in Antwerp has not been utilized for light and traction to anything like the extent it has been used in many smaller cities. The traveler who studies the shop windows observes that gas and the Welsbach light are to be seen in many places, while the incandescent light is not so largely used.

In the Banque d'Anvers there are a dozen Welsbach burners to one incandescent lamp and the latter cannnot be said to give as satisfactory results as the former. To one accustomed to the brilliant electrical displays in the streets of New York, there is a feeling of disappointment over the dimly lighted streets of this old city. Antwerp is a place of surprises owing to the marked contrast it presents alongside of our American seaboard cities. For a city of at least 240,000 inhabitants, it possesses poor facilities for handling traffic. The electric motor here is quite unfamiliar. One looks in vain for motor cars and trailers.

The old time slow horse car still holds sway and seems to satisfy the public. When asked why electricity isn't used, the average man replies "We don't do things so fast here. We go slow and sure." One of the book stores has in its window an illustration of an accident to a trolley car, in which numerous passengers are shown in all stages of injury and fright. The people look on and remain satisfied. They prefer to have their neighbors use electricity meanwhile, but it is only a question of time when the electric motor will come here to stay.

It is curious to observe the open cars running here. They are 14 to 16 feet long, have eight seats and when fully loaded hold but few passengers. Perhaps the most peculiar thing about them is the low foot (or running) board. These foot boards are suspended by cross braces and only have a clearance of an inch and a half, being nearly even with the pavement. There is no danger of turning an ankle or being thrown when entering, or alighting from, the car.

The driver is in uniform, likewise the conductor, and they resemble soldiers, minus guns. Some of the cars start when the conductor's whistle is blown, but others are started by the blowing of a horn. There is not much adherence to schedule, as it is a sort of "Go as you please." There are cars enough for present demands, as the people are inclined to walk. They haven't been educated to ride. Fares are low and for 10 centimes (2 c.) one may travel a considerable distance. The open cars are mounted on single trucks and the wheels rise above the floor over a foot. This trips the passengers and is most objectionable. The ordinary hand brake is used and closely resembles the American type. As this part of Belgium is very flat, there are no grades. A tee rail is used in many places and the rest is a girder rail such as your readers are familiar with. Single track with turnouts will be found, although in certain districts there is a double track. The paving is good and mostly the well-known Belgian block. Wood is scarce and the telegraph poles are of iron, raised considerably above the low houses. In numerous places the track, instead of being at the side or in the middle of the street, runs diagonally across and very near the curb. It often happens that when a sharp turn is made, the rear end swings around and brushes against the sidewalk pedestrians. They take it good-naturedly and seem to expect such a result. When fares are collected the conductor issues a printed receipt therefor. Advertisements are few and are on the sides above the roof. Instead of several, there usually is but one in large white letters on a blue background.

There are several lines, the Tramways Maritimes and Nationaux leading to the quays and prominent stores and parks. There is an omnibus company which operates the 'busses and also a company which controls carettes such as abound in Philadelphia, with the exception that one horse here hauls a load that two or three are required to handle in America.

It is unlikely that the great electrical companies on the Continent will rest content with equipping systems elsewhere. They must sooner or later get an entrance into this ancient town and there is likely to be a good field. Operating expenses will be light, as coal can be landed cheaply. When the electric light comes into greater use there will be profit in central stations for furnishing light and power under one roof.

THE ELECTRICAL PROPERTIES OF SELENIUM.

In a paper read before the London Physical Society Mr. Shelford Bidwell gives the following conclusions as the results of his investigations:—(1) The conductivity of crystalline selenium appears to depend principally on the impurities which it contains in the form of metallic selenides. It may be that the selenides conduct electrolytically, and that the influence of light in increasing the conductivity is to be attributed to its property of facilitating the combination of selenium with metals in contact with it. (2) A selenium cell having platinum electrodes, and made with selenium, to which about 3 per cent. of cuprous selenide has been added, is, even though unannealed, greatly superior, both in conductivity and sensitiveness, to a similar cell made with ordinary selenium and annealed for several hours. (3) Red selenium in contact with copper or brass is quickly darkened by the actions of light, owing, it is suggested, to the formation of a selenide. (4) Crystalline selenium is porous, and absorbs moisture from the air, and it is this moisture that causes the polarization of selenium after the passage of a current. (5) The presence of moisture is not essential to sensitiveness, but appears to be in a slight degree favorable to it. (6) If cuprous selenide is made the cathode in an electrolytic cell, and a strip of platinum the anode in water, red selenium, mixed with detached particles of the selenide, is deposited in the water. (7) The photo-electric currents, sometimes set up when light falls upon selenium, are dependent upon the presence of moisture, and are no doubt of voltaic origin. (8) Perfectly dry selenium is below platinum in the thermo-electric series.

ELECTRIC TRANSPORTATION DEPARTMENT.

THE DEY-GRISWOLD HYDRAULIC GEARING FOR ELECTRIC CARS.

The economy to be attained by a motor run continuously at constant speed in electric railway work has given rise to a number of devices in the way of gearing to make this possible; and among these the hydraulic gear has received some attention. More recently Mr. Harry E. Dey, of the Dey-Griswold Co., has devoted his attention to this subject and his work is embodied in the new hydraulic gear and motor arrangement illustrated in the accompanying engravings.

In the Dey system, the single motor used is suspended by springs at the centre of the truck. Both field and armature revolve, the former having ten poles, but only one coil, and being shunt wound. The armature is series drum wound, the coils being wound on a lathe and slipped over the teeth on the inner surface of the cylinder. Four brushes are used. These bear on the end of the commutator for the prevention of the unequal pressure caused by centrifugal force. The spider extends out over the brushes and protects all parts from dust. Slides provide for the inspection of brushes, etc.

The armature and the field have separate shafts, and on each of these is placed a pump having four cylinders arranged radially, as shown in Fig. 1. The pistons are single-acting and all four are attached in the same plane to one crank-pin by adjustable rings A A, Fig. 2. This crank-pin may be said to be the key to the whole problem. It is adjustable while in motion, moving 1½ inches either side of the centre. This gives a variable pumping capacity from maximum to zero in one direction, and from zero up to maximum in the opposite direction, without steps or reversing valves.

On the axles are placed what are known as the gear type of fluid motors, Fig. 3. Flexible pipes connect these with the pumps which are arranged in series with the fluid motors,—pumps and motors alternating. The pipes, pumps, and fluid motors are filled with oil. It is evident that when the pumps are operated, they will force the oil through the pipes to the fluid motors on the axles and cause them to revolve. The greater the capacity of the pumps, the greater will be the speed of the car; and the axle motor will in turn act as a pump and drive the pumps themselves as fluid motors, and the motor as a dynamo whenever mechanical power is applied to the axles as in the case of descending grades, etc. It is also apparent that when the crank-pin is at the centre, the pistons will be held rigid, and it would then be utterly impossible for the wheels to turn, although the motor be running continuously. If the pin is moved from the centre, one-sixteenth of an inch, for example, a stroke of one-eighth inch will be produced. The motor would then have an immense leverage or torque for starting, as the ratio of reduction would be twenty-four times as high as at maximum speed. To this would be added the fly-wheel capacity of the continuously revolving field and armature. There is, therefore, absolutely no danger of ever being stalled when it is possible to get a grip on the rails. Besides this, as the whole apparatus is piped in series, if one set of wheels is inclined to slip, the power is applied to the other axle; that is, both axles are practically geared together.

As the crank-pin is moved further from the centre, it increases the length of the stroke, and, consequently, the pumping capacity and speed of the car. If the pin be moved back, the axle will immediately have to decrease its speed, or the pump and electric motor increase theirs. An increase in the motor will instantly convert it into a dynamo as the counter E. M. F. will overcome the applied E. M. F. This would act as the best of electric brakes until the car comes to its proper speed. If the pin be carried past the centre, it will reverse the direction of the flow of oil to the axles, because of the change in the relative positions of the valve B and the pin. This would immediately start the wheels revolving in a direction opposite to that of the car. There are only two valves in the whole apparatus,—one on each pump,—and they are entirely automatic. The construction is simple, there being one casting with two plain ports keyed to the shaft.

The governing of the crank-pin is as follows: The crank-pin and the beveled plates D and E form practically one piece. Though made in two parts, one part threads into the other. These plates slide in the dove-tailed grooves of plates F and G. Plate E has a rack which meshes with the pinion H; the latter is keyed to shaft I which has four parallel high pitch threads cut upon it. The nut J threads on these, and also slides in a groove in K which is an extension of the main shaft, with which all of these parts revolve. L is normally a stationary nut threaded on the

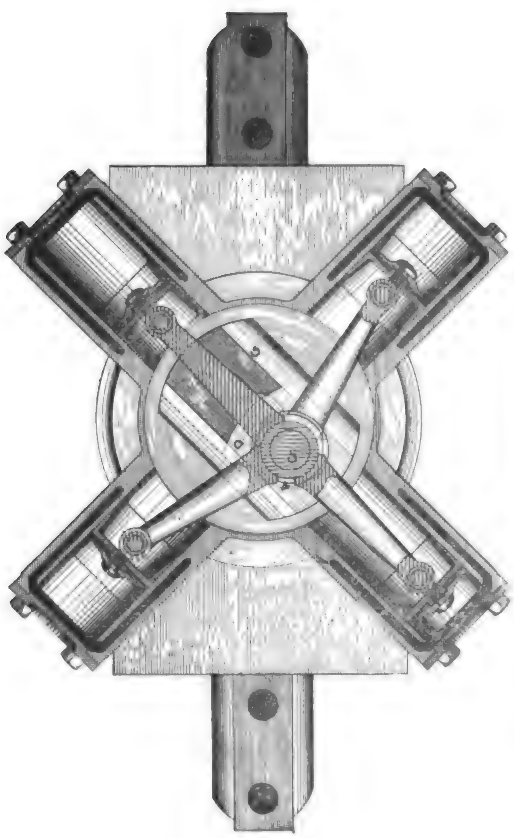


Fig. 1.—Section Through Pump.

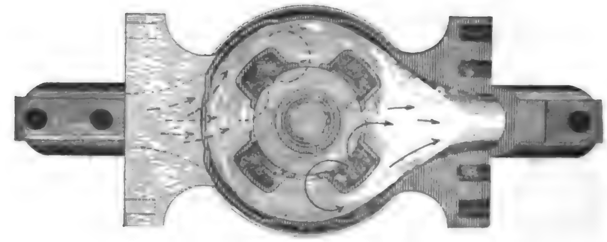

Fig. 4.—Section Through Valve.

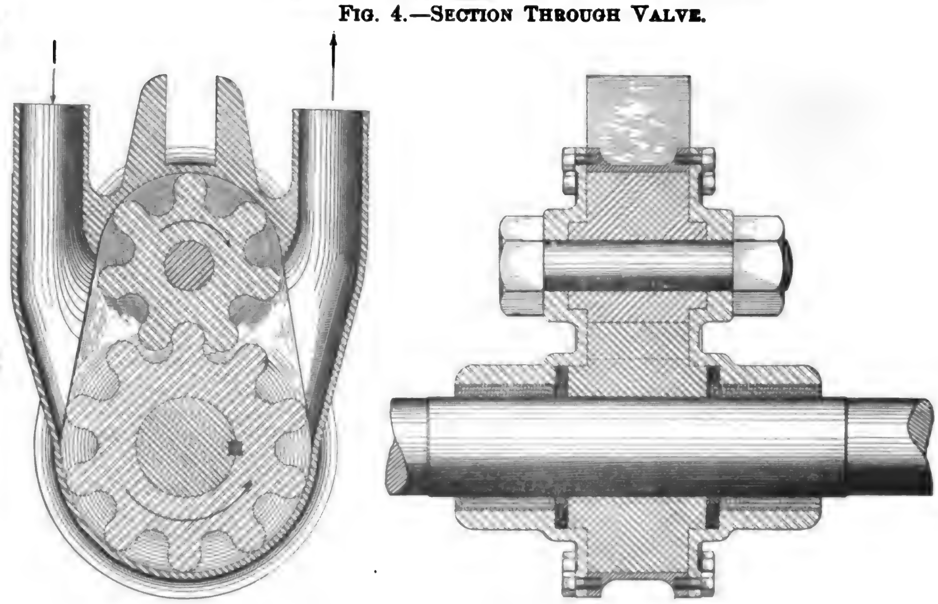

Fig. 3.—Sections of Fluid Motor on Car Axle.

outside and having the nut J freely revolving inside of it. These keep their relative positions by means of the collar shown. Working in the thread of nut L is the sprocket nut M which is connected by a chain to a sprocket and crank-handle on the platform. The turning of this handle turns the nut M which draws L in or out. This in turn draws K in or out, revolving I and H to move the crank pin. It will be seen that in any position the crank pin is locked.

The fluid motor will be readily understood by an inspection of

Some of the advantages claimed for this system are: A very high efficiency, saving in many cases 50 per cent. of the current. The largest saving would be made on streets like Broadway, New York, where the stops and starts are so frequent and the running is so slow; also where there are many hills. In places like Kansas City, St. Paul, and Pittsburg this saving would probably be exceeded. These results are accounted for on these grounds: First, the very high efficiency of a shunt motor, governing the amount of current in almost direct proportion to the mechanical load,

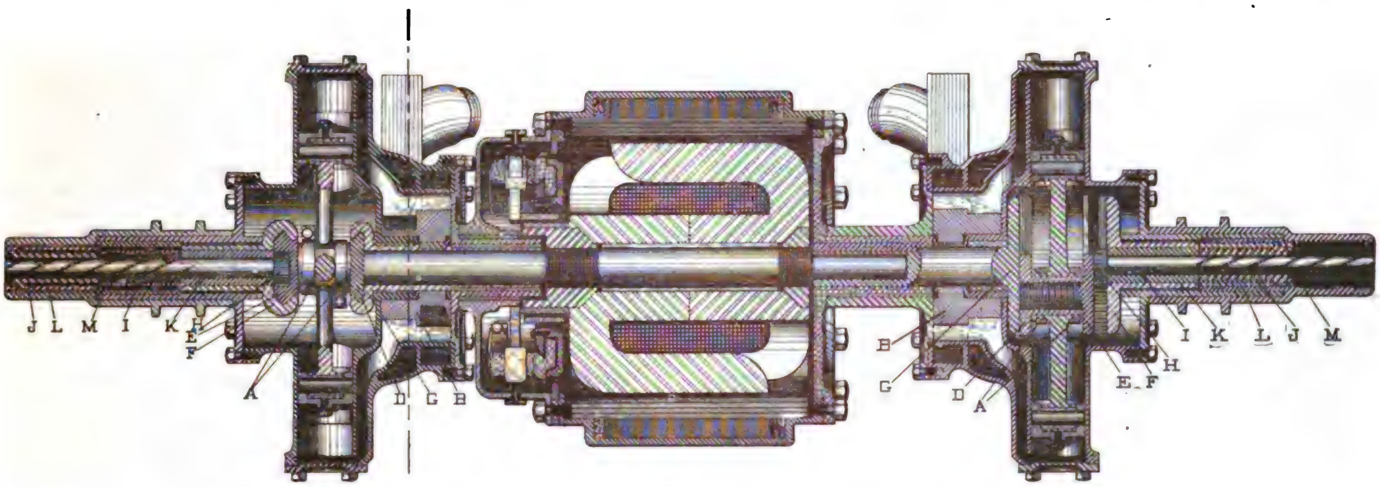

FIG. 2.—DEY-GRISWOLD SYSTEM.—SECTION THROUGH ELECTRIC MOTOR AND PUMPS.

Fig. 3. The direction of the arrows should be carefully noted. Fig. 4 shows a section through the valve.

It is a well known fact that several times the requisite motive power is placed on a car in order to obtain the necessary torque to start, for the rated horse-power is not delivered until regular speed is reached. Take, for example, a motor designed to run at 600 revolutions and furnish 20 horse-power. In starting up, a speed of 6 revolutions delivers only $\frac{1}{100}$ of 20 or $\frac{1}{5}$ horse-power, unless overloaded. The shunt motor described, always running

instead of wasting it in resistances or over-saturated field coils. Second, the large percentage returned to the line on down grades or whenever overcoming the momentum of the car; on the Brooklyn bridge it is claimed the amount returned to the line would be just 33 per cent. of the total current required. Third, a reduction of one and a quarter tons in weight, because there is only one 20 horse-power motor whose weight is only half that of the usual type of motor of the same power, on account of the revolving field and armature. Practically, the weight of one and

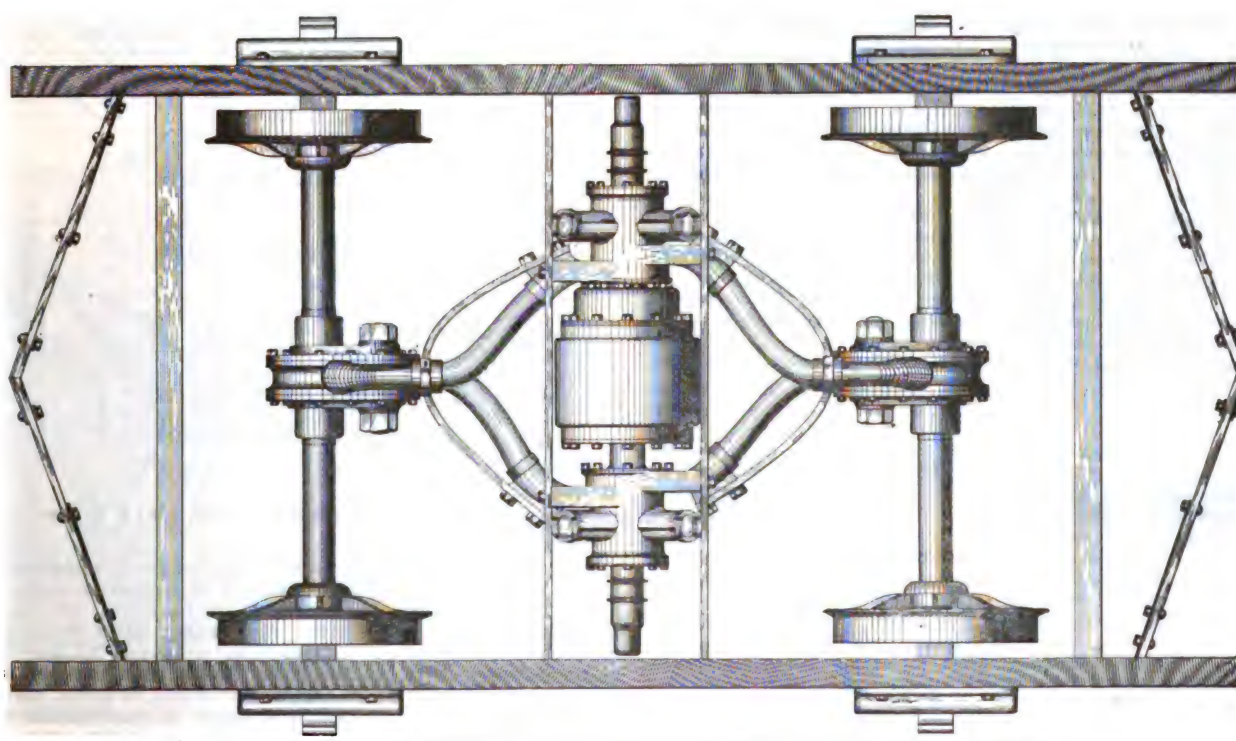

FIG. 5.—DEY-GRISWOLD SYSTEM.—PLAN VIEW OF MOTOR AND HYDRAULIC MECHANISM.

at a constant speed, will always deliver its rated power, and, if necessary, triple it for a short time.

Fig. 5 shows a plan of the motor and pump mounted on the truck.

The company proposes to build a 20 horse-power outfit to begin with, and will experiment downward, expecting to stop at about 10 horse-power. Twenty-four inch car wheels will be used. The 20 horse-power motor has an outside diameter of 17 inches.

one-half motors, or 3,000 pounds, is dispensed with; against this comes the weight of the pumps, 350 pounds. The fluid motors counterbalance the weight of gears which they displace. The cumbersome controllers, rheostats, and brakes are also unnecessary. The revolution of both field and armature also adds a small gain in efficiency, the $C^2 R$ loss being divided by two, approximately. If a fifty per cent. saving is made in coal, it follows that a corresponding saving is made in cost of power-house, feed

wires, and many other minor items. The car is under absolute control with one handle. It can be started very quickly, yet easily, and stopped much more readily than with hand or air brakes. The braking begins simultaneously with the beginning of the movement of the handle. A fraction of a second so saved would, in many cases, have prevented loss of life in the past. The motor is spring mounted, and the inertia blow of axle-mounted motors is prevented.

By using a synchronous motor, the alternating current would be available, and the problem of utilizing the alternating current for railway purposes, it is believed, be practically solved.

When used on trains, a fluid motor can be placed on each axle throughout the train, utilizing the traction of all. This would permit very quick starting and stopping without jerks. A broken coupling-pin would be unknown; indeed, coupling-pins could almost be dispensed with entirely.

As a financial competitor, this system, it is claimed, can readily hold its own. About sixty per cent. of the motor cost is saved, and the expensive controllers, rheostats, and hand or air brakes are not required.

The motor may be built for any desired maximum speed, beyond which it would be impossible for the motorman to run it, regardless of down grades, etc. If, however, the chief engineer should wish to increase that speed, he may do so indefinitely by placing a small resistance in the field circuit. There is no danger from burnouts as the motor is never started with a load. The brushes and the commutator will last longer, because they may be placed with their proper lead. The car floor will be very low, and there will be very little noise aside from the hum of the brushes.

Mr. Dey also claims that this system affords the best of brakes, disposes of the separate brake handle, and provides a dynamo, a reverser, a governor and other adjuncts without adding a single piece of mechanism.

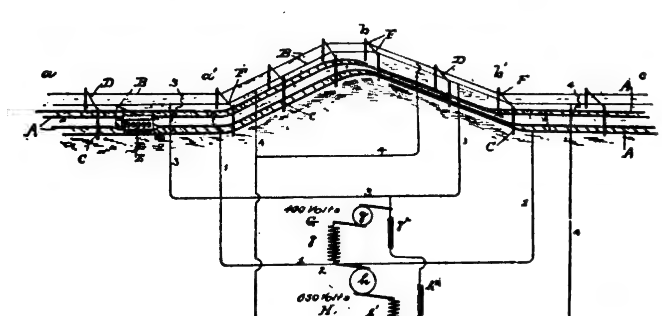
The Dey-Griswold Co. has been recently incorporated, with offices at 108 Fulton street, this city. Harry E. Dey is president and general manager; Fred. B. Griswold, vice-president; W. C. Thacher, secretary and treasurer; and Charles A. Gaines, superintendent. The directors include the above named and Mr. Franz Nemo Roehrich. The company will do a general electrical manufacturing business including the system described above, and modifications for elevators and electric carriages. They are also developing an induction system for street-cars which has a complete magnetic circuit.

THE HENRY COMBINED THREE-WIRE AND BOOSTER SYSTEM FOR ELECTRIC RAILWAYS.

Where heavy grades exist on the routes of electric railways, or where congested traffic throws a heavy load on a particular portion of the system, special heavy feeders are now provided and it has been proposed to reduce the expense of these by employing boosters, or auxiliary machines to supply the heavily loaded section with an increased potential.

To accomplish the same object but without the use of an extra generator, Mr. John C. Henry has devised a system consisting of a three-wire circuit fed by two generators of different constant potential, the line being divided into insulated sections, each of which is connected with that one of the generators which produces the potential suitable for that section. The rails of the track form the neutral conductor.

The portion of road shown in the accompanying diagram is



Henry's Combined 3-Wire and Booster Railway System.

supposed to be divided into sections requiring different voltages. The section from a to a' is a congested part of the city, where the cars E must run slowly. The section from a' to b is an up and down grade; that from b to b', a down and up grade; that from b' to c, a suburban district where the cars may run rapidly. On the sections where it is desired to run slowly the maximum voltage is fixed at, say, four hundred, and this may be the voltage, also, on all downgrades. On the upgrades and also in the suburban portions the voltage is arranged at six hundred and fifty. The sections of the working conductors on which these different voltages are used are electrically separated by insulating connectors F.

Current is supplied to this system by two constant potential generators G H, the former giving a voltage of four hundred and the latter of six hundred and fifty. These machines are compound wound, the armature g h and series-coils g' h' being connected in series, and the shunt-coils g^2 h^2 being also connected in series, forming a single shunt for the two machines. The neutral conductor 1 is connected with the series-field-coil circuit between the two machines at 2, and also with the rails of the track A, which are electrically continuous. The positive brush of the dynamo G is connected by the feeders 3 with those sections of the working conductor on which a potential of four hundred volts is to be maintained, while the negative brush of the dynamo H is connected by the feeders 4 with those sections of the line on which the potential is to be six hundred and fifty.

It will be seen that this system operates substantially in the same manner as a three-wire system of the usual construction, and that it also supplies different portions of the line with different voltages without the use of an auxiliary dynamo. The peculiar connection of the shunt-coils is of especial importance, and has been found to be essential where constant potential dynamos of different voltages are connected together in series.

WIGHTMAN'S STREET RAILWAY MOTOR.

It is generally acknowledged that the introduction of the series-parallel controller for regulating street railways was one of the most important advances in the art and has resulted in a marked economy of current consumption. This method is of course confined to cases where double motor equipments are

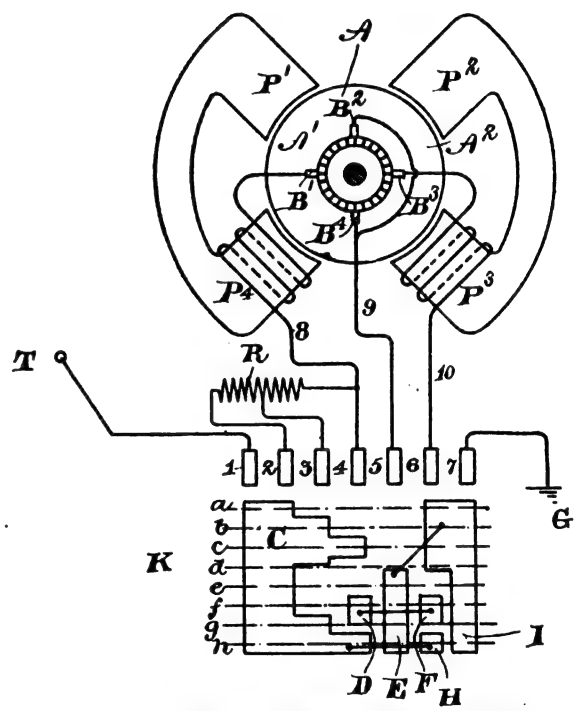


Fig. 1.—Wightman's Street Railway Motor.

used, but single equipments are still called for in some cases and with a view to affording a like method of regulation on a single motor car, Mr. Merle J. Wightman, of Scranton, who has done much original work in electric railroading, has devised a most ingenious arrangement. The method employed by Mr. Wightman consists in first operating the motor as a two-pole motor with the two halves of its armature running in series, and then, by the interposition of suitable resistance in combination with a shunt around one-half of the motor, changing this arrangement to one in which the motor operates as a four-pole motor with the two halves of its armature in multiple.

The accompanying illustration, Fig. 1 shows the arrangement diagrammatically. A^1 A^2 are the two halves of the armature; B^1 B^2 are the two brushes which are always active and B^3 B^4 those used as negative brushes when the motor is operated as a four-pole machine.

P^1 to P^4 are the field magnet poles, two of which are wound poles and two unwound or consequent poles. The direction of winding upon the poles P^3 P^4 is such that when the current passes in

series through the two halves of the armature, both of these poles are magnetized in the same sense, either north or south. The two upper poles P^1 P^2 are then of consequent and opposite polarity to the two lower ones. When the current, however, is reversed in the pole P^3, this pole becomes of opposite polarity to P^4, and the four poles then alternate in polarity around the armature, converting the machine into a four-pole motor. At this time the brushes B^3 B^4 become active, having been open-circuited before. A resistance R is provided and furnishes further means of regulating the speed and torque as well as preventing undue sparking incident to the changes of connections.

K is the controller, the cylindrical contacts of which are shown

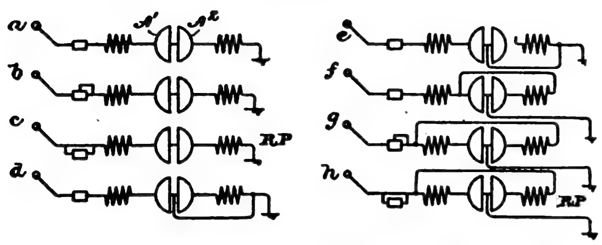

FIG. 2.—CONNECTIONS OF WIGHTMAN REGULATOR.

developed in plane. The controller is provided with contacts C, D, E, F, H, and I, and with cross-connections, and also with fixed contacts or brushes 1 to 7. The dotted lines represent the different working positions of the controller corresponding to the diagrams *a* to *h* in Fig. 2. In the latter diagram the positions marked R P indicate running positions, the others only being used while the motor is changing its speed.

COAL-HANDLING MACHINERY IN ELECTRICAL PLANTS.

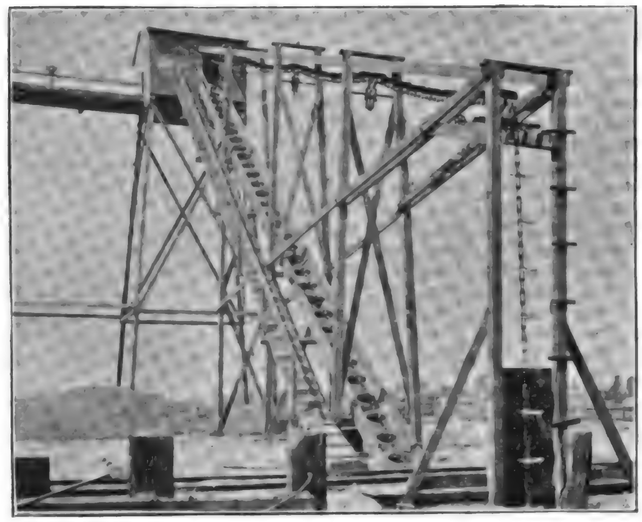
THE development of electric power for the operation of railways, as well as for use in industrial plants all over the country, has called for the installation of many large power houses, in which the consumption of fuel for the production of electricity is concentrated. In nearly all cases large units of power being employed and the growing tendency being toward even larger, the designing of these power plants involves, as a very important consideration, the most economical method of handling coal in large quantities between the carts, cars or boats and the boiler room floor. The cost of handling fuel in large quantities has become quite an item in the operating expenses of power plants, and labor-saving machinery for this purpose has consequently received a great deal of careful study by mechanical engineers. Many of the largest equipments of this class have been designed and erected by The Link-Belt Engineering Co., of Nicetown, Philadelphia, and among them that of the Hestonville, Mantua & Fairmount Park Passenger Railway Co., of Philadelphia, which, as it differs from other power plants in that city, by receiving its coal from boats, we have selected for illustration in this issue

COAL CONVEYER, HESTONVILLE, MANTUA & FAIRMOUNT PARK R. R., PHILADELPHIA, PA.

The road itself was very fully illustrated and described in THE ELECTRICAL ENGINEER of January 9, 1895.

The power plant is situated upon the Schuylkill River front, about 100 feet back from the pier line. The coal, brought to the wharf by canal boat, is automatically conveyed to the storage bin, which extends the entire length of the boiler house and has a capacity of 300 tons. From this bin the coal is tapped by chutes, which deliver it directly in front of the boilers.

The machinery employed for the coal-handling consists of a dock-leg elevator, inclined conveyer and horizontal conveyer,



COAL CONVEYER, WELLMAN IRON AND STEEL CO., THURLOW, PA.

which operate as follows: The elevator, suspended at the end of a boom, consists of two strands of Ewart link-belting, to which strong buckets are bolted, the whole being housed in a wooden casing and arranged for raising and lowering as may be required. The coal after being elevated to a proper height is discharged into a chute, which by gravity delivers it into the foot of an inclined trough, in which a scraping conveyor works. By this conveyer it is carried to the top of the incline and at that point delivered into a short chute, which feeds into a horizontal trough extending over the top and entire length of the storage bin. In this horizontal trough, a scraping conveyer also works. The discharging from this horizontal trough into the storage bin is effected by means of a number of gates in the trough bottom, which latter can be opened and closed by small hand wheels. In both of these conveyers the well known "Dodge" chain is used. The troughs are of the standard form always employed in this kind of work and are made up of sections of wrought-iron with depressed lap-joints, thus insuring a continuously smooth trough; and as the flights are provided with wearing shoes, the working of the conveyer is attended with but little noise. On the inclined conveyer the supporting of the return chain is effected by a continuous guide consisting of two angle-irons supported over the entire length of trough and upon which the flights slide, the latter being at their edges also fitted with wearing shoes. This construction contributes to smooth running and reduces the wear on the chain.

The accompanying illustration shows clearly the driving gear. The entire machinery is driven by a small vertical engine, which is located upon the floor of the power house and below the head of the inclined conveyer. The power is transmitted through an 8 inch belt to a countershaft, which carries a "Link-Belt" disc friction clutch and a spur pinion, which latter drives a spur gear, upon whose shaft are also fixed the driving sprocket wheels of the inclined conveyer and horizontal conveyor. Thus the pull on the inclined conveyer is at the delivery end of the loaded chain. The friction clutch is so arranged as to act upon the spur pinion, and hence makes it possible to run the machinery independently of the conveyors.

The power necessary for driving the elevator is taken from a rope sheave located upon the countershaft referred to above and transmitted by means of a manilla rope to a similar sized sheave located in the dock-leg tower. The shaft of this latter sheave carries a spur pinion, which, by means of an intermediate wheel, drives a spur wheel, upon whose shaft is a Ewart sprocket wheel. From this Ewart sprocket wheel the necessary power for driving the elevator is transmitted through a No. 88 chain to the head shaft of the elevator. The intermediate wheel just referred to, driven by the spur pinion, has upon its shaft a sprocket wheel which, by means of a No. 88 Ewart chain, drives a spur

pinion and wheel, upon whose latter shaft is a drum. Upon this drum the crane chain is wound which supports the dock-leg elevator, so that the raising or lowering of the elevator is effected by the revolving of the drum, and its motion is given to it through a "Link-Belt" disc friction clutch.

This plant was designed to provide for the handling of 40 tons of coal per hour, which it easily accomplishes. In all of this machinery, the capacity has a large margin, so that it can always be increased by a slight acceleration in the speed at which it operates, without unduly taxing the driving gear. The power required for this plant is comparatively small, and, with the exception of the small amount of handling required to feed the coal into the foot of the elevator, is entirely automatic and shows such good results as to forcibly suggest the adoption of similar systems elsewhere.

Another plant for the storage of coal which has attracted considerable attention, is one which was also constructed by The Link-Belt Engineering Co. for the Wellman Iron & Steel Co., of Thurlow, Pa. This will handle upwards of 40 tons per hour, and although somewhat similar to the one described above, presents some features not included in the foregoing. In most cases the power required to drive this machinery is furnished either by an independent engine or from a countershaft, but here an electric motor is used, which adds one more to the many uses to which these motors have been put. The use of an electric motor in this case presented advantages over a small steam engine, inasmuch as it is placed on the top of the tower, which is at some distance from the steam plant and does not involve the loss attendant upon condensation in long steam pipes. The motor was furnished and installed by the Wellman Co., and makes 500 turns per minute.

The view here given shows the inclined conveyer and head, or driving end, of the horizontal conveyer. The system employed is covered by patents controlled by The Link-Belt Engineering Co. and is a simple one. From the time the car is run over the hopper, into which it is unloaded, until the coal is stored there is no shovelling whatever. The plant consists of an inclined trough and a horizontal distributing trough, in both of which scraping conveyers work, operated by means of Dodge chain.

The system of storing is effected in the following manner: Beneath the entering track there is a hopper, into which the cars are dumped. By referring to the accompanying cut it will be seen that the inclined conveyer runs under the tracks and below the hopper, its foot wheel being located just below the bottom of the hopper. A discharge door in the bottom of the hopper delivers the coal by gravity into the foot of the inclined conveyer that leads to the head of a horizontal conveyer. The chain then starting with its load at the bottom of the hopper between the rails, carries it up the trough to the top of the incline and there discharges it into a chute, which in turn delivers it into the horizontal distributing conveyer. This latter conveyer is 100 feet long and the coal is discharged from it through doors located at intervals of ten feet throughout its length. Its trough is supported upon wooden framing at a distance of 35 feet from the ground. Starting at the foot of the incline, under the hopper, the chain moves to the top of the incline, returns over the bends, by passing over idle pulleys, and thence travels in a vertical direction back to the foot of the incline. The return chain of the horizontal conveyer is supported by similar idle pulleys.

The power required for driving the conveyers is transmitted from the motor through a train of gear wheels consisting of two spur pinions and wheels and a bevel pinion and wheel, the bevel pinion and wheel driving the head wheel of the inclined conveyer. All of the driving gear is at the top of the framing of the inclined conveyer, where the electric motor is also located, and as the driving sprocket wheel of the inclined conveyer is at the head of the incline, the pull is at the delivery end of the chain. The troughs are of the standard form and constructed of wrought-iron with lap joints.

TROLLEY CAR BUSINESS IN ST. LOUIS.

Notwithstanding the increase in bicycle riding here, says a St. Louis paper, our street car companies continue to do an immense business. Their reports for the second quarter of the year show a total of 26,826,083 passengers carried in the three months, as compared with 24,778,660 in the corresponding period of last year. This is an increase of over 8 per cent. One company gained over a million passengers, and another nearly a million. Each, however, operates several lines. The largest gain in percentage was made by the Broadway cable road's extension, the old bobtail, double-fare, mule line from Lowell to Baden. It is operated now with electricity, and in connection with the Broadway cable road, passengers being transferred from one to the other without extra charge. The worst showing of all is that of the Jefferson avenue line. Instead of increasing its business, it lost 57,000 passengers. Fortunately for the company's receipts, this horse car line—the only one in the city—is now being converted into a first-class electric road. Its patronage, too, will be doubled as soon as the change is made.

CAN LIGHTNING RUN TROLLEY CARS?

The following story which we reproduce in all the effulgence of the reporter's vocabulary emanates from Norwich, Conn.—

"The latest prank performed by Nutmeg lightning was starting motorman Harlow Ladd's trolley car and whizzing it ten rods along the track without any help from the rumbling dynamos that were grinding out refined electricity in the company's works half a mile away. Harlow had reached the end of the Greeneville route, switched the electric current from the motor, and, brass handle bars in hand, stepped across the street upon the side-walk. The trolley was still connected with the wire. Right overhead a big, round thunder cloud, black and threatening, spun slowly about, portentous with muttering thunder. The rest of the firmament was serene and blue, unsullied by a patch of vapor.

"Suddenly the frowning cloud mass was riven by a zigzag shaft of glittering flame that was shot straight downward against the car motor and made it ring like a bronze bell smitten with a hammer. The report, said Motorman Ladd, was far louder and stronger than a pistol shot. Then, with surprise, amounting almost to awe, the motorman beheld his car, impelled by crude electricity from the clouds, shoot forward eight or ten rods along the track. It did not move very rapidly, and by running he overtook and boarded it just before it came to a halt on the rather stiff grade. The bolt had quickly exhausted itself. In the opinion of motormen and other street railroad operatives, the thunderbolt, heavily charged with electricity, acted on the car motor momentarily in precisely the same way as the regular electric current from the company's works.

"In the same storm a trolley car operated by Motorman Ed Ladd, a cousin of Harlow's, was touched up in a similar lively way on Franklin square in this city. The car was in motion at the time. A long, zigzag tongue of flame was shot like a javelin straight through the open car. Luckily there were no passengers aboard. Conductor John Cousins, who was on the rear platform and had his hand on the brass railing, received a considerable shock. Motorman Ladd was still more severely shocked. Most of the bolt went into the platform switchbox with a ringing report."

Admitting that a car standing still was actually set in motion on being struck by lightning, it would be interesting to inquire just to what extent and in what manner the energy of the discharge itself contributed to the movement of the car. Perhaps some of our readers may have some light to throw on the subject.

CUTTING STEAM FARES IN NEW JERSEY.

It is reported that there is to be a decided cut in the suburban rates of the Central Railroad of New Jersey, on account of the loss of business due to the competition of the trolley line from Elizabeth to Newark. It is said also that the business of the company has been injured by the establishment of a trolley route from Bayonne to Jersey City and New York. The rumor was to the effect that the reduction was to be made this week.

PUSHING THE GETTYSBURG RAILROAD PROJECT.

The new electric railroad from Washington across the state of Maryland to Gettysburg, Pa., a distance of seventy-five miles, is now being pushed by a company of Washington capitalists headed by President Frank Brown of the Baltimore Traction Company. The plan includes three important branch lines aside from the main road. The first of these is from Cooksville eastward on the Frederick turnpike to Ellicott City, and thence to Baltimore, a distance of twenty-two miles; the second is from Eldersburgh to Gwynn Oak Park, about an equal distance, and the third branch is from Westminster to Reisterstown, connecting with Baltimore, twenty-eight miles away. "The idea of connecting the nation's capital with the nation's greatest battlefield," says President Brown, "is a splendid one. Encampments and reunions of many military organizations are held there every year, and besides the thousands that go there from Washington now, there would be thousands of others if a direct route could be built which would take passengers through at a good speed at all seasons of the year without causing them the inconvenience of changing cars. The number of Southerners who visit the battlefield is increasing rapidly each year, and the proposed electric line would give them a good route with only one change of cars at Washington. The legal authority under which this network of new railways would be constructed is found in an amended charter granted by the last Legislature of Maryland to the Maryland Immigration and Trust Company of Baltimore, formerly called the Southern Real Estate and Trust Company. The company is given the right "to construct, equip, and operate steam, electric and other railways in this state." The Pennsylvania rights and the county commissioners' permits to use the public turnpikes must be secured, but as the proposed road will furnish means of transportation in a section which has suffered for the lack of such facilities, it is believed that the necessary charters will be secured without difficulty.

TROLLEY PARTIES IN PHILADELPHIA.

The latest "trolley party" in Philadelphia was that organized for the benefit of the German Hospital. It comprised 61 cars loaded with 3,000 people, and then there were 500 left behind. The parade was headed by a car bearing the Gambrinus band.

"THE electric road is bringing down the price and rentals of city residence property. The country is growing at the expense of the city." So says the Annapolis, Md., *Capital.*

THE CAST-WELDED RAILJOINT.

THE results achieved with the cast-welded railjoint seem to have placed this method in considerable favor, due to the fact that the joint so welded is not only held in a viselike grip but also bonded at the same time.

The Falk Manufacturing Company, of Milwaukee, is turning out as rapidly as possible, in its own shops, several duplicate outfits for putting in its so-called "cast-weld" rail joint, as described in the technical journals. One of these outfits, ready for shipment, is illustrated in Fig. 1, for which we are indebted to the *Street Railway Journal*. The portable cupola, as shown on trucks of any of the machines in case of sandy or muddy roads. Each outfit is equipped with three ladles, one or two for use and one for reserve. The cupola handles 8,000 to 9,050 lbs. of metal in one heat, and this makes approximately eighty joints. Two heats are run in one day where the workmen are not interrupted by traffic on the road, it requiring about three hours to run a heat and about an equal length of time for the cupola to cool sufficient for recharging. When work is confined strictly to the night time, after traffic hours, but one heat can be run.

In casting joints, large iron moulds are used. These moulds are in pairs and are heated hot before clamped in place at the joint. In the illustration is shown, back of the cupola truck, an auxiliary

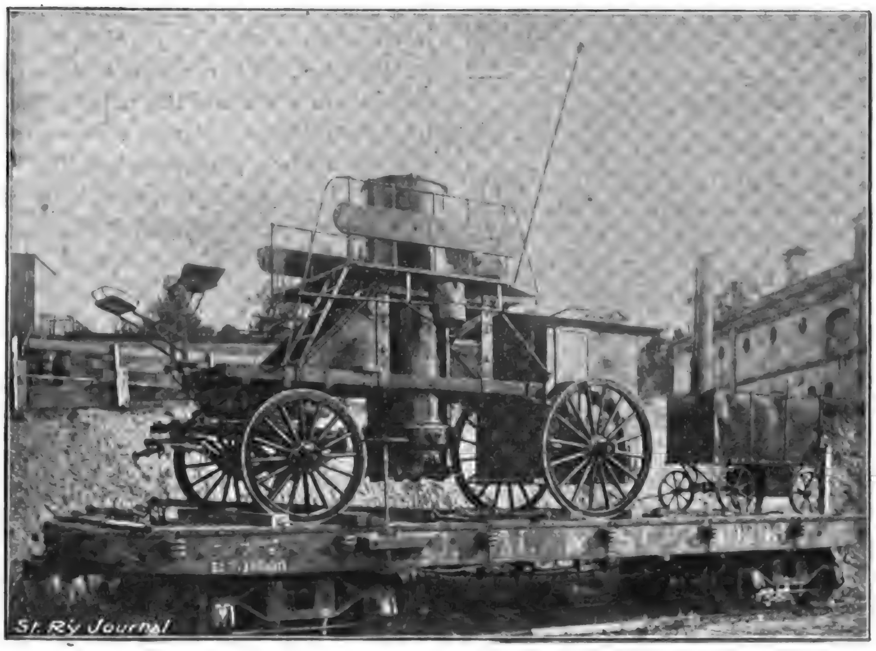


FIG. 1.—PORTABLE CUPOLA AND MOULD HEATER FOR CAST-WELDED RAIL JOINTS.

the car for shipment, is pivotally suspended on the large truck like a mariner's compass, so that it always hangs perpendicular no matter how rough the road may be.

Coke is carried in the box in front of the cupola, and the pig iron for the heat is piled in front of the coke, under the driver's seat and on the platform surrounding the top of the cupola. Mounted on the same truck and back of the cupola is the blower. The blower on the machine illustrated is operated by an electric motor, with a fan on the motor shaft. Power for the motor is conducted from the trolley wire by a regular trolley pole. The outfits heretofore turned out have a steam engine in place of the motor for operating the blower, and the outfits now under construction will also be equipped with engines instead of motors, so that they will be entirely independent of power from a street railway company, and can be used equally as well on cable roads, where there would be no power for an electric motor.

All of these outfits are built standard, with all principal parts interchangeable.

The weight complete before charging is about 12,000 lbs., and they are handled by three horses abreast. The company has sets of wheels having ten inch tread, and which can be used on the outfit, termed the mould heater. This wagon has a fire box below, and has three layers of grates arranged inside the box and on which the moulds are placed for heating. Fig. 2 shows the method of filling the mould and Fig. 3, the complete joint.

It is very natural that many improvements would be suggested as the company progressed with its work. One of the most notable and important of these is a clamp so arranged as to insure a perfectly level and straight joint when welding new rails with the ends abutting.

FIG. 2.—CASTING THE RAIL JOINT.

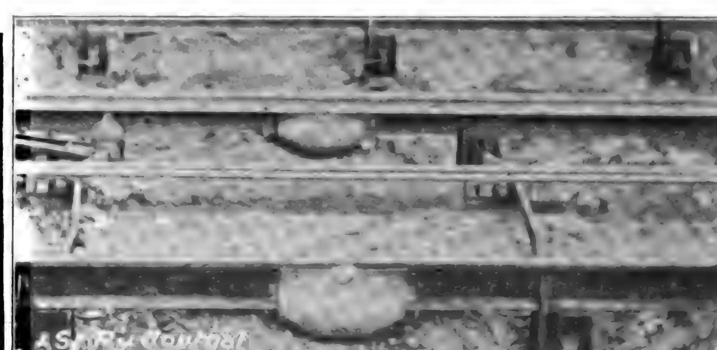

FIG. 3.—THE FINISHED CAST RAIL JOINT.

A LONG ELECTRIC RAILWAY IN FLORIDA.

It is said that an electric railroad from Jacksonville to St. Augustine will be in operation by Jan. 1, 1896. The road will be constructed by the Jacksonville and Tampa Bay Improved Railway Company. This company was chartered by the Legislature to construct and operate a line of railway from Jacksonville to some point on Tampa Bay, with branches running to several important interior towns of the State. The company was promised a grant of 7,000 acres of land per mile for every mile actually built.

SUPPLEMENT.

MUNICIPAL "GAS" AND THE PEOPLE'S LAMPS.

It is perfectly safe to assume that "municipal plants" is one of the subjects of discussion that will not down, but it is deeply to be regretted that some partisans of municipal ownership should be so utterly and so frightfully reckless in the statements they make. When there are so many interesting new things to be paid attention to, it is really a serious pity that scant leisure and valuable space should have to be given up to the correction of grave misstatements that cannot help the cause they are intended to advance and which, nevertheless, prejudice the public mind. There seems to be no help for it, however, and just now we find the papers flooded with wild yarns by "Prof." Frank Parsons, who might well be called the Prince of Liars, if he were not likely to take it as a compliment. This gentleman, to whom we would gladly attribute honest purposes, has, it appears, been expounding his arithmetic of electric lighting in the *Arena*, and an article of his in the August number on "The People's Lamps," is presumably a fair sample of his average effort in this particular branch of fiction.

We may premise our remarks by saying that we have ourselves no prejudice against municipal plants as such. We take pleasure in describing good ones when found, and it will not be forgotten that we made recently a most impartial study and exhaustive digest of the subject with the co-operation, as expert, of Mr. H. A. Foster. The subject is a broad one, and needs all the evidence on it that can possibly be secured, but it has already had too much of the flagrant and violent misrepresentation in which "Prof." Parsons permits himself to indulge.

Mr. Parsons has so many pages of absolute falsities, it is hard to pick out any as worse than the others, but we will take one of his tables as a little sample of his exuberantly imaginative figuring:

TABLE X.

Cost per lamp per year before and after public ownership, the "after" service being the same as or better than the service it replaced.

	Before.	After.
Bangor, Me.	$150	$48
Lewiston, Me.	182	55
Peabody, Mass.	185	62
Bay City, Mich.	110	58
Huntington, Ind.	146	50
Goshen, Ind.	156	77
Bloomington, Ill.	111	51
Chicago, Ill.	250	96
Elgin, Ill.	266	43
Aurora, Ill.	326	70
Fairfield, Ia.	378	70
Marshalltown, Ia.	125	27
Jacksonville, Fla.	24	5

Mr. Parsons may well call these "marvellous facts." We have seen nothing so marvellous since reading "Munchausen's Travels." Time is too short to expose all the lies in this table. We will simply remark that in Chicago the city plant has been supplying light to itself not at $96 per year per light, but at nearly $170. Fairfield, Ia., gets from itself 285 c. p. per hour for one cent. or about half what the great private companies in New York City give. Moreover the Fairfield plant itemizes no repairs although it has been shut down from damage for two weeks at a time! Moreover, again, Fairfield *never* paid a private company $378 a year per light! Aurora, Ill.,

buys coal at $1.80 per ton, and yet it only gets 447 c. p. per hour for one cent; while San Francisco, where the private company has to pay $5.90 per ton, gets 400 c. p. per hour for one cent, or as much as vaunted Huntington, Ind., which charges the salary of its superintendent to the fire department. Bay City instead of getting its light at $58, is in reality mulcting itself at the rate of $140, or more than Buffalo, where the private company gets only $127.50 for 4,000 hours per year.

It is natural that "Prof." Parsons should be paralyzed by astonishment at his own results. Such charlatans usually are. It is part of the show. "Imagine a city," he says "one year paying a private company $200 or $300 for a street lamp and the next year making the light itself at a total cost of from $40 to $70." Yes, indeed, imagine it, for that is all that anybody was ever able to do. It never was seen yet, and we do not think it ever will be seen.

Another piece of enterprise is shown in Table XI, where we are coolly informed that Bangor and Lewiston are on a parity with Boston, the former at $34 and Lewiston at $43 while Boston pays a private company $139. As a matter of fact, when all expenses are figured in, Bangor is spending about $104½ per year per light; while in Lewiston a private company has offered the city service at .02 dollar per hour, while it is spending .0291 dollar itself. But the value of the comparison is seen in the fact that Boston is getting 645 C. P. per hour for 1 cent while Lewiston, with water power, is only getting 687—a good showing for Boston where every expense is far beyond what it could be in Lewiston. The same defence applies to the absurd comparison of Dunkirk, N. Y. with New York City. Here is what Mr. Parsons says:

"Turn to Dunkirk and New York. Both use 480-watt lamps burning all night every night. In both the motive power is steam; coal is $2 a ton in Dunkirk, $3 in New York, a difference of $5 per arc in favor of Dunkirk. But this is more than overcome by the volume and density of business in New York. The Dunkirk plant is confined to the business of lighting 75 street arcs, while the New York plants run 2,625 street arcs, and an enormous commercial system that gives them a heavy load all day as well as all night. If New York owned her electric system, and managed it with honest efficiency, she would get her light for less than the Dunkirk cost."

Merely prefacing our comment with the fervent prayer that New York may have no additions to its municipal enterprises, we would point out that even on its own showing, with many items of expense left out, little Dunkirk only gets 718 C. P. per hour for one cent, while New York, which everyone knows to be the costliest city in the country to do business in, gets its electric light from private companies at the rate of 555 C. P. per hour for 1 cent; which is a good deal better than Herkimer, N. Y. pretends to do, and more than twice as good as the performance of Jamestown, N. Y.

To be brief, these municipal figures of "Prof." Parsons and others of his type are "gas," and prove nothing except the unreliability of their authors. But they might well be expected from a man who puts forth the following as his creed:

"It is all a very simple matter. If the people acquire a business that M owns, the people will get the profits that M now gets."

That leaves nothing to be said.

COMMUTATOR AND BRUSH FRICTION.

We are pleased to present elsewhere in this issue what we believe to be the first definite information concerning brush friction and resistance. It is strange, indeed, that in spite of the very advanced state of dynamo and motor design, such an important factor is practically ignored or at best is not considered quantitatively. Eddy currents and hysteresis do not consume much larger percentages of the total energy, nevertheless they are determined with the greatest care and accuracy.

The experiments and resulting data given by Messrs. Cox and Buck in their thesis will now enable engineers to treat brush friction and resistance as a quantitative part of the design of dynamos, and the surface and pressure of brushes corresponding to a given amount of power lost by friction and resistance may be definitely specified.

Results are given for a smooth cast iron pulley as well as for the ordinary copper commutator. These show that the heterogeneous surface of the latter gives greater friction and resistance, as might be expected. This is interesting as a comparison, but we suspect that the experiments with iron surfaces were due to Professor Crocker's influence, and that he intends to apply the results to unipolar dynamos which he advocated in his Institute paper a year ago. From this point of view the results are encouraging, since the friction and resistance are low as we have seen, and *contrary to the very generally accepted idea the contact resistance is only slightly increased by oiling the surface,* whereas the friction is enormously reduced. The data given must certainly be of great assistance in designing a unipolar dynamo.

CONSTANT SPEED RAILWAY MOTORS.

RAILWAY motor regulation has occupied much of the attention of electrical engineers and still claims it, and rightly so, for there are few details in connection with railway work that have a greater influence on the coal economy at the central station than the operation of the motors themselves. However the station superintendent may strive at perfection in his department, his efforts will be largely nullified by heavy fluctuating drafts of current carrying with them irregular and wasteful action of the engines. The series parallel controller, has, it is true, done much to mitigate this evil, but even at the present time the starting current taken by electric railway motors and when running at slow speed is greater than ideal conditions would call for. To reach these ideals, it has been proposed to operate by means of a continuously revolving constant speed shunt motor with variable gearing, and a number of plans have been brought forward with this end in view. The hydraulic gear seems to have a strong fascination for inventors in this department and it certainly presents advantages not to be met with in rigid mechanical gears. We present on another page the latest work in this field due to Mr. Harry E. Dey, which will well repay study. With the alternating current gradually tending towards practical railway work such a system of gearing permitting the employment of a single-phase synchronous motor, might find an immediate application.

TELEPHONY.

THE CALLENDER AUTOMATIC TELEPHONE EXCHANGE SYSTEM.

OUR readers will recall the detailed and illustrated description of this system which appeared in our issue of January 9th. Since then the apparatus has been much improved and the demonstration lately given of the perfected system has attracted considerable attention.

The system, it will be recalled, is founded upon a percentage basis, the "calls" being the units of work. A subscriber on turning in a call to the exchange has there assigned to him a signal registering mechanism. The numerical value of his signal or call for connection with some other telephone is then indicated and immediately afterwards it is registered in the numeralizing division of the apparatus. The signal registering mechanism then passes out of his control for use by other subscribers. These mechanisms, as well as all others in the system, are present in exact proportion to their use as determined by the statistics showing the maximum number of calls likely to be received at the busiest part of the day.

The calling subscriber having registered the number of the telephone with which he desires connection has then assigned to him one of the connecting and signaling mechanisms not then in use. He is then connected to the telephone called, if that telephone is not in use at the time, and a "connected" signal of one long ring is sent from the exchange over the lines of both telephones. The lines are then left connected through a percentage connecting mechanism, all other apparatus previously in use for obtaining the connection and for signaling the telephones when connected having reverted automatically to the normal condition, free for the common use of other subscribers. The connecting mechanisms constitute the largest percentage group found in the system—ten per cent. of the total number of subscribers—allowing twenty per cent., or one fifth, of the telephones to be interconnected at one time. The other mechanisms form groups of lesser percentage proportions, the signal registering group, for instance, being only one per cent. of the whole number of telephones connected to the exchange.

The improvements recently effected are as follows:—The numeralizing apparatus with its system of fractional circuits has been eliminated entirely and its functions are now performed by other circuits in use at other times for other work. The separating apparatus for automatically separating the various series of impulses constituting the "call" has been improved and simplified, its cost being reduced to a minimum and its action made positive in every way.

The system as now constructed can be installed at only a fraction of the cost of installing the ordinary hand-operated switchboard. It is claimed for this percentage system that, unlike any other, it becomes cheaper per capita as the size of the exchange is increased, thus making it an important factor in obtaining much lower rates than are possible with any other system. Our engraving shows the Callender exchange apparatus required for 100 subscribers, as exhibited in operation in the Decker Building, Union Square, this city.

THE CALLENDER 100-SUBSCRIBER AUTOMATIC TELEPHONE EXCHANGE.

THE STANDARD TELEPHONE AND ELECTRIC COMPANY.

THE recently published circular of the Standard Telephone and Electric Co., of Madison, Wis., describes the characteristic features of the Standard loud speaking telephone, which embodies the Mildé long-distance transmitter. This type of instrument has been adopted by the French House of Parliament, the Admiralty and War Offices, Post-office telephone exchange, railway companies, etc., by the British, Italian, Spanish and South American Governments; some of the telephone companies of Italy and Egypt, and in the United States by railway companies and other corporations. It is claimed that the "Mildé" transmitter does not pack or get out of order, does not require adjustment, and is "as sensitive as a Blake, and as powerful as a solid-back."

These telephones have been operated successfully over upwards of 500 miles of ordinary telegraph wire, with numerous relays in circuit, run on poles in parallel with other wires over which telegraph messages were being transmitted and where the induction was very great. Under all these conditions the "Standard"

telephone has proved itself equal to the best instruments made for long distance work, and admirably adapted for ordinary use.

The company is now actively pushing its business, especially in the automatic exchange system outfits. These are complete with switches, and adapted for use in towns, villages, interior plants, and all purposes where a limited number of telephones are installed in a circumscribed area. Another instrument which has been well received is their Standard No. 2, or "Warehouse" telephone, for connection between different departments. No exchange is necessary. Each instrument having its switchboard, instant communication is secured by turning the switch to the desired number. The lines can be used by more than two persons at one time. For instance, with a system of nine instruments, Nos. 1 and 3, 2 and 8, 5 and 7, 4 and 9 can converse simultaneously without interfering with one another.

A TELEPHONE ROMANCE IN MAINE.

Here is a little romance that occurred recently in Portland. He was a clerk in a large wholesale house and used the telephone constantly. At certain periods his calls were answered by a sweet voice, which seemed to sooth his tired, worn-out nerves and strengthen him wonderfully. He grew to listen for that voice, dreamed of it, and finally it became a part of his life. One evening in the theatre he heard it behind him and recognized it at once. For a long time he sat as one dazed and dared not look at the possessor of the voice for fear he would be disappointed. But he wasn't, and now they're engaged.

BELL TELEPHONE.

The Bell Company is doing, says the *Boston Journal*, what all corporations of the kind working under broad patents, must do to insure their stability. It is coming to rely on its strength as a manufacturing corporation and its ability to meet any future competitor by offering the best service at the lowest rate. The reduction of its charges to subordinate companies enables these to extend their business and swell their receipts, gains which will ultimately appear in the net results of those subordinate companies. It is an appreciation of this that has led to the buying for investment of the stocks of those companies. The Bell figures for the month ending July 20 are :

	1895.	1894.	Inc.
Gross output	13,837	6,430	7,407
Returned	7,518	5,754	1,759
Net output	6,324	676	5,648

TELEPHONE NOTES.

GREAT FALLS, MONT.—The Great Falls and Lewistown telephone line is now complete.

CLARKSVILLE, TENN.—A project is on foot to have Dover, Erin and other points connected with this city by telephone, and a subscription list to this end is now being circulated.

FORT DODGE, IA.—The city council has granted a franchise to the Phoenix Telephone Company, of Indianapolis, to operate in this city.

MIDDLETOWN, N. Y.—At a meeting of the Board of Directors of the Orange County Telephone Company Mr. A. R. Pflaum was selected as general manager of the company.

SAVANNAH, GA.—The erection of the building for the Southern Bell Telephone Company will begin Oct. 1, and it will be ready for occupancy by January 1. It will cost $25,000.

BRAZIL, IND.—A company of Lebanon capitalists, headed by Frank C. Reagan, have secured a franchise from the city of Brazil and will put in a telephone system at that place.

HOUSTON, TEX.—Mr. Ben Kiam, one of the directors of the Texas Telegraph and Telephone company, left recently for the East. The purpose of his visit was to contract for instruments to be used by the new company.

MIDDLETOWN, N. Y.—The Sullivan County Telephone Co. has about seventy-five telephones in operation on its lines. The system is now being extended to Callicoon Depot by way of North Branch and Hortonville.

DECATUR, ILL.—The stockholders of the Decatur Mutual Telephone Company are trying to get possession of the plant, which was sold under chattel mortgage to John A. Brown for $9,000. It is worth $25,000 and the receipts have been $17,000, with expenditures $16,000 and $700 not accounted for.

SYRACUSE, N. Y.—Plans for the new telephone building have been submitted by Henry Wilkinson and approved.

MT. VERNON SPRINGS, N. C.—J. M. Foust will establish an exchange.

FRANKFORT, IND.—A rate war is on between the Frankfort Telephone Company and the Central Union Telephone Company.

STOCKBRIDGE, MASS.—The promoters of a telephone exchange for Stockbridge have thus far secured thirty subscribers, and the work of putting up the wires will begin immediately.

VINEYARD HAVEN, MASS.—Dr. C. F. Lane has made a contract with P. H. Carr of Waterbury, Conn., to complete his Island telephone system and put it in first-class condition, with all the newest improvements.

WAUSAU, WIS.—The Wausau Telephone company, which was recently organized with a capital of $10,000, has engaged as manager F. P. Crocker, for years the manager of the Wisconsin Telephone company in Wausau.

SIMSBURY, CONN.—The Southern New England Telephone Co. is preparing to connect the towns of Granby, Canton, East Granby, Avon and the village of Tarriffville with Simsbury, the above places forming the Simsbury exchange.

TRENTON, N. J.—If the present plans of the New Jersey Standard Telephone Company are carried out, Trentonians are to enjoy the benefits of a telephone service at less than one-half the present rates.

ALICE, TEX.—The Alice, Wade City & Corpus Christi Telephone Co. has been organized with a capital stock of $10,000; John Wade, president; George Newberry, vice-president, and L. G. Collins, secretary and treasurer.

MEMPHIS, TENN.—The Memphis Telephone Company has filed its charter in the register's office. The names of the charter members are : J. T. Jefferson, J. C. Neeley, Fred Orgill, E. G. Robinson and J. C. Neeley, Jr.

ANDERSON, IND.—F. W. Bradbury has sold out his interest in the local American Telephone Construction Company, of this city, to his partner, C. M. Harriman, who thus becomes owner of the New Castle plant and the franchises at Memphis, Tenn., and Winchester, this State.

UNIONTOWN, PA.—The Home Telephone company of this place, which secured a charter a year ago, have decided to go ahead with the construction of an exchange. The local Bell Telephone exchange has more than doubled its list of subscribers since it reduced the yearly rental 50 per cent.

WHEELING, W. VA.—Mr. M. R. Wolff, general manager of the Central District Telephone Company, of Wheeling, has completed arrangements for the erection of a line from Morgantown to Uniontown, Pa., which will be the means of connecting the interior of West Virginia with Pittsburg.

CLEVELAND, O.—The movement to secure better service and cheaper rates from the telephone company or else to get a new company in the city has been most favorably received and a large number of subscribers have indorsed the agitation. The leader in the movement is Mr. W. H. Gobielle.

PENDLETON, WASH.—This city will soon be connected with Long Creek by telephone. Crews of men are now at work stringing and laying poles, and telephones are in operation for a distance of about 20 miles. When Long Creek, 100 miles distant, has been reached, the extension to Burns will be made, and Grant county will have its first telephone line.

HAMILTON, O.—Articles have been filed with the secretary of state for the incorporation of the Hamilton, Hughes and Monroe Telephone Co. The capital stock is $5,000, divided into 500 shares of $10 each and the incorporators are F. M. Hughes, C. E. Griesmer, A. E. Schenck, J. E. Hughes, D. S. Rose, J. P. LeSourd and L. C. Shafor.

INDIANAPOLIS, IND.—The Phoenix Telephone Company had a hearing before the Board of Works, and made a proposition that the company would pay 5 per cent. of its gross income four years from the date of beginning business, and would continue to pay that rate of special tax the rest of the term of the contract.

ELIZABETH, N. J.—The New York and New Jersey Telephone Company has secured a temporary injunction against the Elizabeth Mutual Telephone Company, which it was shown had not organized under the State law, and had failed to deposit with the State Treasurer $10,000, being one-third of its capital. The company will be compelled to reorganize entirely.

LONG DISTANCE TRANSMISSION AT 10,000 VOLTS.

(The Pomona Plant.)—III.

BY GEORGE HERBERT WINSLOW.

Some curious conditions met with in the operation of the plant are shown in the ampere curves in Fig. 4, which were taken during very wet weather. Taking the maximum load measurements at 7 P. M. for March 14th and 8th, we note that the total apparent energy delivered by the sub-stations is 78 per cent. and 75 per cent., respectively, of that delivered by the generator, while for a smaller load at 9 P. M. the respective percentages decrease to 47.6 per cent. and 48.6 per cent. in spite of the fact that the apparent energy delivered by the generator is in the latter case only half as great as in the former. The results are due to changes in the angle of lag caused by changing the load.

In the cañon curve of March 8th, the load at 9.30 P. M. is seen to have increased considerably, although the sub-station loads were decreasing. This increase was due to the fact that the rain which had previously ceased to fall at Pomona, began again.

The electrical resistance of the Pomona circuit is 74.9 ohms and that of San Bernardino 156.4 ohms at about 90 degrees F.

The insulation resistance of the circuits varies from far beyond the limits of an 11-megohm bridge in dry, hot summer weather to as low as 0.65 megohm during light rain. The latter value is that obtained with the two San Bernardino wires in series, and represents an insulation-resistance per mile of over 37 megohms. On a clear, sunny day the insulation-resistances of one Pomona wire and of one San Bernardino wire were respectively 11 megohms and 5½ megohms, which are in the exact relation which would be expected.

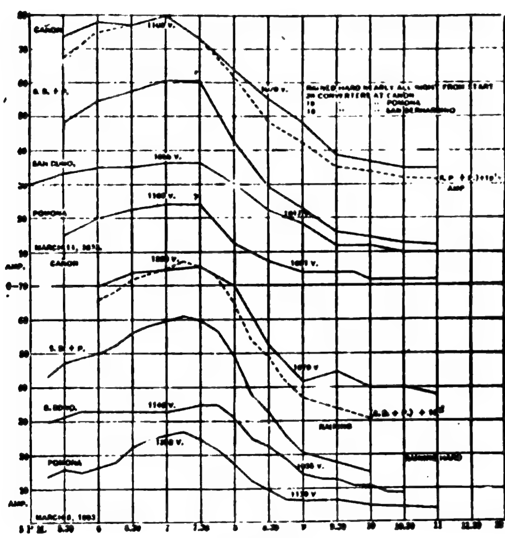

Fig. 4.

The lines cannot be tested for grounds or for continuity with a magneto bell, as their capacity is such that the bell will ring loudly when the wire is perfectly insulated and the circuit open. This capacity also prevents the use of the ordinary converter test for line leakage, as the lamp on the secondary will burn as though there were a ground even when the line is perfectly clear. By adding lamps, however, the light may be cut down until the last lamp added extinguishes them all. This would not occur if the light of the first lamp was due to a difference of potential on the primary caused by a ground, as then the added lamps would become as bright as the first. The primary current is thus seen to be limited, and to be due to the capacity of the line. If the proper number of lamps has been added to just secure darkness when the line is known to be free from grounds the converter may be used to show grounds on that line, since the presence of a ground will cause all the lamps to brighten. The line test should only be made after ascertaining with one lamp that the generator is not grounded, as otherwise the leakage current for the greater number of lamps might burn the insulation of the generator.

A very good example of Prof. Fleming's "condenser effect" was met with in the Summer of 1893, while the engineer was trying this converter test for measuring line leakage. The primary of a 1000—100 volt converter was connected between the ground and one terminal of the generator, the other terminal of the latter being connected to one wire of the Pomona circuit. The resulting secondary pressure was 30 volts, which made one lamp burn dimly. When ten lamps were turned on, the pressure dropped to 14 volts. When all lamps were turned off the pressure became ten times as great, or 140 volts. One generator brush was then raised, and the second leg of the circuit was connected to the first. On completing the circuit again there was a sudden flash of the armature, followed by a crackling noise and a brush discharge which lasted until the circuit was broken. The Pomona wires were then disconnected from the dynamo terminal, which was left free. With this arrangement faint sparks and a glow were noticed, as though the armature winding were grounded on the core, but a Wheatstone bridge test showed an insulation resistance of over 10 megohms. Since then the machine has been used regularly and has not broken down, so it is evident the spark must have resulted from a sudden increase of the potential of the armature winding above that of its core, which latter was permanently connected to earth.

This sudden increase may be explained as follows. On closing the circuit the condenser formed by the line and the earth began to discharge through the metallic circuit afforded by the armature and converter windings, but the inductance of this circuit checked the discharge so quickly as to produce an excessive pressure which could only be relieved by the discharge taking place through the insulation of the armature-winding to the grounded core, which is what happened.

A comparison of the San Bernardino switchboard voltmeter was made with a Weston instrument and gave important results.

1st. With *no load* the San Bernardino instrument was about 14 volts (11.2 per cent.) low at 125 volts, while at 97 volts it was only 11.7 volts (12 per cent.) low.

2nd. With a *city load* (inductive, consisting of lightly loaded converters) of 7½ amperes it was 11 volts low between 107 and 96 volts, while for 15 amperes it was only 8 5 volts low. Further increase in load caused further reduction in the difference, until for 40 amperes the instrument was only 5 volts low.

3rd. With a *tank load* (non-inductive) of 9 amperes it was only 9 volts low at 99 volts, and as the load was increased the difference decreased until for 97 amperes the instrument read the same as the Weston.

It is evident from these observations that a voltmeter which consists essentially of a solenoid and a movable core, is not the proper type of instrument for circuits such as those used in the present case, in which transmission circuits of great length are used in conjunction with transformers. The voltage at San Bernardino during the tests was therefore measured with a Weston portable voltmeter.

THE NEW CONSOLIDATED POWER HOUSE FOR TOLEDO, O.

It has already been announced in these pages that all the electrical plants and companies in Toledo have been consolidated, and that a new power house is to be built for the whole service. The work has been entrusted to Mr. F. Sargent, M. E., of Sargent & Lundy, whose central station designing is to be seen in several of the largest plants in the country.

The new station will have many new features, and so far as steam economy goes, that is, the indicated horse power in the cylinder of the engine as compared with the coal burned, will, it is expected, be lower than any station yet built. In fact, if the engine builders carry out their contract successfully the chances for ever building a station to beat Toledo on steam economy will be very slim. The only way to beat it will be by increasing the steam pressure. The electrical features of the station are not altogether in the line of the highest economy, although the margin is small. Mr. Sargent, as consulting engineer, is combining the old Western Electric station, which was purely an arc lighting station, the Toledo Electric Company, which ran arc lights, incandescent lights and stationary power service, and the Toledo Consolidated Street Railway Company, which operates eighty miles of railway. The new station will be located at the corner of Water and Madison Streets on the river front. The engine room will be 70 feet wide by 200 feet long, and the boiler room 40 feet wide by 200 feet long. The plans for the station are being prepared by Messrs. D. H. Burnham & Company, the Chicago architects. All the old engines and electrical railway station apparatus will be abandoned. The arc light machines from both stations, the alternating current incandescent machinery, and the stationary power machinery will, however, be used in the new station, to be driven from a line of shafting. Contracts for the new machinery have been awarded as follows: Four engines to carry an economical load of 700 H. P. each, and a maximum load of 1200 H. P. of the cross compound type, have been awarded to the American Wheelock Engine Company, the engines to be built at Wm. Cramp & Sons Ship & Engine Building Company's works, Philadelphia. These engines are guaranteed to produce an indicated horse power on 13 lbs. of steam per hour, including such steam as may be used for jackets and reheating coils. Three of these engines will have General Electric Company, 500 kilowatt direct coupled railway generators on the shaft for operating the railway service. The fly wheel of each engine is also provided with grooves for rope drive to the line of shafting operating the lighting machinery, the arrangement being such that the engines can be used jointly or

separately for either the lighting machinery or the railway work. This arrangement admits of a comparatively small investment in engines, considering the large amount of work and variety of work to be done.

The fourth engine has no railway generator on it, but otherwise it is exactly like the other engines, the intention being to equip it with a railway generator at a later date. The boilers have been awarded to the Heine Boiler Company of St. Louis, and the Green Economizer Co. have secured the contract for economizers.

The heart of the city is to be equipped with an underground system, and it has been decided to use the Edison three wire system for this purpose, so that the plant when finished will be arranged as follows:—Municipal arc lighting by series arc light system; arc and incandescent lighting and stationary power service for the centre of the town by Edison three wire system; incandescent lighting for the outskirts and suburbs by the alternating current system using the old machinery for the present; railway service by direct coupled General Electric generators; and a special service of 500 volt direct current for operating elevators and heavy power work, such as would be liable to interfere with the lighting service, if operated from the three wire system, for the centre of the town. All of the apparatus outside of the railway generators will be driven from the line shaft, for the present, but it is expected to put in direct coupled generators for the Edison three wire system as soon as the load will warrant using units of 500 H. P. capacity.

THE MINERAL INDUSTRY, ESPECIALLY ALUMINUM AND COPPER.

The *Engineering and Mining Journal* has issued in a carefully prepared statistical supplement some valuable facts from "The Mineral World," Volume III of which is now issuing, in regard to the mineral and metal production of the United States in 1893 and 1894.

The total value of the mineral products of the country, as given in a table prepared by Mr. Richard P. Rothwell, editor of the *Engineering and Mining Journal*, was $615,887,108 in 1893, and $553,352,996 in 1894, showing a decrease in values (not quantities) last year of $62,534,112, or 10 per cent.

To arrive at the net value of the mineral and metal production in each year, a deduction is made from the total for that of substances, the value of which has necessarily been duplicated in the tables. Such, for instance, are the antimony ore used in making the metal; the bauxite used in making alum and aluminum; the coal—chiefly slack—used in making coke; the copper used in making sulphate; most of the lead used in making white lead; the manganese ore used in making spiegeleisen and ferromanganese, which are included in pig iron, zinc used in making zinc oxide, etc., etc. A careful estimate of the proper amount of these deductions gives $13,000,000 in 1894, and $15,000,000 in 1893, which would leave the net total value of our mineral production in 1893 equivalent to $600,887,108; and in 1894 equivalent to $540,352,996.

To make a fair comparison between the two years, the quantities of the several articles produced should be examined. It is impossible, of course, to give any total in quantities when so many materials and different units of measure are taken into consideration. The only total that can be given is that of values and the decrease in this amount is in most cases very much greater than the falling off in actual quantities produced. The year 1894 will long be remembered as one of low prices and in almost every industry values were brought down to a point lower than had ever been before known. It was a repetition of the experience of former panic periods, only intensified in our own case by the general distrust provoked by the condition of the currency. It seems to be an unavoidable result of the concentration of capital and the continual improvement in processes which characterize the present age, that production should increase in a greater ratio than consumption, and that at greater or less intervals there should be a period when a halt must be called until the demand can again increase to the level of the supply; and 1894 being one of those periods the producers suffered accordingly.

Specially interesting from an electrical point of view in the comprehensive table are the data on aluminum and copper. These are given as:

Products.	Customary Measures.	1893. Quantity. Customary Measures.	1893. Quantity. Metric Tons.	1893. Value at Place of Production.	1894. Quantity. Customary Measures.	1894. Quantity. Metric Tons.	1894. Value at Place of Production.
METALS.							
Aluminum.	Pounds	a312,000	142	202,800	817,600	371	490,560
Copper	Pounds.	327,255,788	148,441	35,504,314	353,179,997	110,483	33,540,489

To illustrate what has been said with regard to the comparison of values, it will perhaps be well to take a few instances from the table. Thus, while our total production of copper showed an increase of 26,250,000 lbs. the estimated value at the place of production was lower by $1,640,000 in 1894 than in 1893. Again, the production of zinc decreased only 2,250 tons or about 3 per cent., while the value reported was less by about $1,000,000 or 16 6 per cent. The decrease in the production of pig iron was 386,000 tons or 5.5 per cent. while the decrease in value was $21,-900,000 or nearly 24 per cent.; many similar instances might be taken from the table to show that the total reduction in value of the mineral production of $62,534,112, or 10 per cent. represented very much less than that proportion—probably not over 5 or 6 per cent.—in actual quantities produced.

To sum up the matter briefly, the table given shows a moderate decrease in production, a much larger proportional decrease in the value or prices, but in both cases a decrease upon the whole less than the general expectation of its amount. It shows also that in a year of extremely unfavorable conditions the mineral production of the United States by its extent and variety still gives the country the foremost place among the nations of the world—a place which is, above all, surprising, when we consider the comparatively brief period in which the industry has been built up.

The conditions under which the year closes were far more favorable than those with which it opened. The year 1895 is already beginning to show a very great improvement over its predecessor, and there is warrant for believing that 1896 in its turn will show a development exceeding any which has yet been seen in the history of the mineral industry.

THE THERAPEUTIC ACTION OF CURRENTS OF HIGH FREQUENCY.

It is known, *L'Eclairage Electrique* remarks, that M. d'Arsonval has introduced into electrotherapy new processes of electrization based on the employment of currents of high frequency. MM. Apostoli and Berlioz have been experimenting for over a year with one of his methods, self-conduction, upon 65 invalids, and they have come to the following conclusions: Currents of high frequency, when they completely envelop the patient and act by self conduction, are inefficacious and impotent against the majority of hysterical troubles and against certain neuralgic complaints, but the same currents exercise a powerful influence on the nutritive energy.

ANOTHER TELEGRAPH LINE TO ALASKA.

A special dispatch from Seattle, Wash., of July 26, says:—"John W. Mackay will leave on the steamer *Queen* to-morrow morning for Alaska. He is accompanied by C. R. Hosmer, general manager of the Canadian Pacific telegraph, and it is believed his visit north has something to do with the early construction of a telegraph line to Alaska from Vancouver, B. C."

ELECTRIC POWER TRANSMISSION IN VIRGINIA.

A special dispatch from Danville, Va., says: "One of the most gigantic enterprises ever undertaken in Danville is the organization of the Dan River Power and Electric Company, which was effected by the election of the following officers: President, Thomas B. Fitzgerald; vice-president, William P. Bethel; secretary and treasurer, R. A. James. Directors, Frank X. Burton, John H. Schoolfield, James E. Schoolfield and R. Addison Schoolfield. The charter provides for a minimum capital stock of $75,000, with a maximum of $750,000.

TESTING THE ELECTRIC LAUNCHES FOR THE ATLANTA EXPOSITION.

A trial trip was made on July 31, of the first of the six launches contracted for by the Electric Transportation Co., with the Atlanta Exposition authorities. These launches are a portion of the famous World's Fair fleet, of which Gen. C. H. Barney, the president of the new company, was commodore. It is almost needless to say that the trip was made smoothly and successfully, with a party of about a dozen, at a speed varying from 6 to 10 miles an hour on the waters of the upper Harlem River. The boats are to be shipped to Atlanta early this month, all ready for work. The lake at the Exposition is about 1 mile in circumference, and the boats will carry passengers twice around for 25 cents. There are five landings, and the charging station is in Machinery Hall, near the boat house. The boats will themselves constitute a very interesting exhibit, and the Electric Storage Battery Co. will have a fine display of batteries, for all classes of work, in the boat house. The Electric Transportation Co. pays 18 per cent. of its gross receipts for the franchise. Its New York offices are at 27-29 Pine street.

Letters to the Editor.

THE NIAGARA PLANS FOR CANADA.

I have just seen the account of the Niagara work in your journal. There seems to be something wrong about the account of the Canadian proposals. I do not know what plan has been finally decided on. But the plan I submitted was very like if not identical with that on page 571, of your issue of June 26, which you call the plan adopted. It certainly was not the plan with underground chamber which you seem to attribute to me.

W. C. Unwin.

London, July 18, 1895.

[Our attribution of the plan referred to to Prof. Unwin was due to a misunderstanding, and we are, therefore, glad to give space to Prof. Unwin's letter. The plans are correct, however, as printed.—Eds. E. E.]

THE ECONOMY OF CONSTANT POTENTIAL ARC LIGHTING.

Members of the electrical profession are not usually to be accused of running too much in a groove, or of not being open to the reception of new ideas. But the statement that constant current arc lighting is much cheaper than constant potential arc lighting is so often made that it has come to be received as electrical gospel. This statement is again repeated in the Engineer of July 17 by Mr. E. R. Knowles. It seems to be assumed that the loss in resistance on a constant potential circuit is the only factor in the calculation, without considering others which may enter into the sum total of cost. Will Mr. Knowles oblige a seeker after light by considering the following propositions affecting arc lighting, and then put a little of his well-known mathematical skill into working out a correct solution?

Admitting that his proposition is correct, viz., that two 7 ampere arc lamps require 330 watts on a constant current circuit and 385 watts on a constant potential circuit, let him consider the following questions: Has or has it not been determined that a large multipolar generator of the constant potential type is a much more efficient generator than the customary (or any) type of constant current machine? Silvanus P. Thompson in his well known book on "Dynamo Electric Machinery" gives the efficiency of a standard type of constant current machine at 86 per cent. when new. What is it when old? The better class of constant potential machines give an efficiency of 95 per cent. or higher, and retain it. How much does the superior efficiency of the generator help the constant potential lamp?

In a plant of 1,000 arc lights, it would be necessary to run 10 constant current machines of 100 lights each, if the best modern machines are used. With a constant potential system, one machine would easily do the work. Query, what would be the difference in cost of driving the ten machines over the one, either by belting and countershafting from one large engine, or by ten engines direct connected to dynamos? Calculate difference in friction, oil, labor, interest on cost of real estate and building, wear and tear of belting (if any used), and increased depreciation on high speed machines in place of slow speed.

Constant current armatures have been known to burn out. What is a fair allowance per annum for this item, over wear of a good constant potential armature?

If 100-light machines are used on the constant current system, a potential of 5,000 volts or over must be used. What is the danger factor on this class of wiring, and what is the extra risk worth per annum to the company using it?

How much will it cost yearly to maintain good insulation on lines carrying 5,000 volts over the cost of the same work on circuits carrying 220?

Out here in the wild and woolly West some of our college professors are teaching us that as much light can be had from a cored carbon at 8 amperes as is usually obtained from the common carbons with 9½, and at about the same cost per hour for carbons. We are building stations, using constant potential arc lighting for streets and stores, and operate our incandescent circuits from the same direct connected dynamo. We think that results show lower operating expenses and better lighting from these systems than from the old style stations containing several types of dynamos. If we are so very wrong in our conclusions, and Mr. Knowles will show us just where we are wrong, we will repent in sackcloth and ashes and go back to the good old way. We will admit that we use more wire by doing things in this manner, but by running four lamps in series on 220 volts with iron line wire in place of the usual resistance coil, it is surprising how little wire can be made to go a long way, with properly proportioned feeders.

We think that good carbons mean less cost for current, that one big slow speed generator is better than a number of small ones, and that the resistance loss is more than saved in the absence of belting and shafting, in the superior economy and efficiency of the generator, in saving of employees and absence of danger, while the first cost, after paying for more copper, is no more, because we save in machinery, building, real estate, and many other items. If we are so woefully wrong, won't some one please show us just how much we are wrong?

W. N. Stewart.

Minneapolis, Minn., July 24, 1894.

THE FORBES-ROWLAND NIAGARA CONTROVERSY.

In a card supplementing the letter of Prof. Forbes, which appeared in our last issue, that gentleman says in a note to London *Lightning*:—

"It has been pointed out to me that in answering Prof. Rowland's letter on 'Niagara' last week I may have left some people with the impression that he had made recommendations about dynamos which had been adopted. Let me point out that when he says there is to be iron in the armature, and over 25 tons weight, he is saying nothing more than that the Siemens or Ferranti type is not to be used, as all of the designs sent in, about twenty in number, agreed on these features. He never thought of making the external fields revolve, and he wanted the armature to be the revolving part. My design opposed his views on both points. In fact, he had nothing whatever to say that could be of assistance to us, and when he gave in about alternating currents, the directors of the company wanted nothing more."

THE SELF WINDING STOCK TICKER.

BY A. A. KNUDSON.

Having read the article referring to recent improvements in the Stock Quotation Instrument or "Ticker" (so called) in The Electrical Engineer of July 31st, I am reminded of my own early attempts in this direction, a brief statement of which may be of possible interest to some of your readers, as the instrument I produced years ago contained the very principle which is now being so very universally adopted. The improvement referred to, is simply doing away with the weight, used to give power to the train of wheels, and also doing away with most of the wheel train itself, substituting in place of all this a small spring wound by the action of the press magnets, and controlled by a ratchet wheel and pawls. As the instrument is operated, this small spring is continually being wound and can never entirely run down, other magnets in the instrument being employed to actuate or release the escapement.

During the year 1873 while employed as an inspector in the company furnishing printing telegraph instruments for stock quotations in New York—then known as the Gold and Stock Telegraph Co.—a patent was granted me containing this self-winding principle, numbered 140,148 and dated June 24th of that year. This patent however represented an instrument with a separate pair of magnets in the same circuit with the press magnets to do the winding, or as then constructed strained out a spiral spring, the relaxation of which gave power to the escapement wheel. A machine was made however to do the winding, as now, direct from the press mechanism.

The brief history and ultimate fate of this patent may be of some interest. The officers of the Company to whom the instrument was first shown at that time failed to see any particular merit in it, and declined to make an offer for the patent. Later on this instrument was brought to the notice of Hon. Levi P. Morton, the present Governor of New York State, who at that time was interested in the old Atlantic & Pacific Telegraph Co. and with the foresight which has always characterized that gentleman, he saw sufficient merit in the performance of the instrument to purchase the patent on behalf of that company, the intention being to establish a competing system with the company then in the field. Through various causes, however, the scheme fell through, and the patent was finally bought by the Western Union Telegraph Co. in 1876, consigned to a pigeon-hole, where with many others it slept out its natural life of 17 years, expiring in 1890.

Although 23 years have passed since this invention was first made, it is to me no little satisfaction to see it even at this late day coming into such general use; and while much credit is due to those who have applied this principle to the present instruments, I think the records will show that I am entitled to what little credit there may be, of being the first to devise and patent a self winding printing telegraph instrument.

As now made and operated it would be difficult to find a more simple and efficient instrument of its class in the wide field of electro-mechanics. The statement in your article referred to that "some 900 of the 'tickers' in New York City have already been changed from weight machines to self-winders and a large number of new ones are in process of construction," demonstrates the success of the resurrected idea so long buried in oblivion.

Mr. Augustus Noll writes: "I am very much interested in the Data Sheets as arranged by Mr. Albert B. Herrick, which are published as a supplement to The Electrical Engineer."

LITERATURE.

Street Railway Investments: A Study in Values. By Edward E. Higgins. New York. Street Railway Publishing Co., 1895. Price, $2.

THE professed object of the author of this work is to furnish intending investors in and owners of street-railway securities with a trustworthy compilation of statistical information respecting this class of property, and as complete an analysis as may be of the signification of the figures thus far obtainable. While the author is compelled to admit that many of his generalizations and predictions of the probable limits of gross and net earnings of these properties, under different conditions, have unavoidably been based upon data in many respects insufficient, and hence that it is "far from being a satisfactory treatment of a difficult subject," yet it must on the other hand be said unreservedly that it was a work which needed to be written, and also that, under existing conditions, it would hardly have been possible for any one to have achieved a greater measure of success than that with which the author must be credited by a candid and competent critic.

There is a great difference in different States of the Union as to the trustworthiness of the published statistics obtainable. The uniform system of accounting and reports required in Massachusetts secures results, the substantial truthfulness of which is hardly open to question, and the same is measurably true of New York. As to the returns published in some other States, of which New Jersey and Pennsylvania may be mentioned as conspicuous examples, the less said, the better. They are chaotic, misleading, and not infrequently fraudulent. Extensive use has evidently been made by the author of the information gathered by H. C. Adams for the federal census of 1890, which, as he observes "was admirably planned and patiently followed up by detailed correspondence."

The figures thus gathered have been compiled and arranged in great detail upon a large tabular sheet, which folds into a pocket at the back of the book, thus rendering it extremely convenient for reference. This exhibit gives information respecting 189 different centres of population, and the local street railway systems by which they are served, varying in population from 15,000 to a million and a half, and also, in a class by themselves, 12 interurban systems. The presentation is so arranged as to provide for giving full details of the physical characteristics of each case, the population served, the capitalization, indebtedness, gross and net earnings per mile and per capita, etc., while the text is in fact nothing more than a running commentary on the facts exhibited in the tabular schedule. Probably no one would be more ready than the author to admit the various imperfections which must necessarily arise, not merely from the insufficiency in too many cases of the returns as above adverted to, but also from the fact that the majority of the electric systems discussed have been in complete running condition for so short a period that the actual cost of operation, and especially the depreciation figure, is yet largely a matter of guesswork, even in the largest and oldest systems. Nevertheless, in justice to the author, it must be said that in no case has he undertaken to be more positive in his deductions and predictions than the accessible facts appear to justify, and for this reason, his cautiously expressed opinions are justly entitled to much weight.

The plan of treatment which has been adopted, and which appears to be an eminently judicious one, is to group the properties in a number of classes, the divisions between which are determined by the population served, these divisions being fixed, for convenience, at 15,000, 25,000, 50,000, 100,000 and 500,000 inhabitants; the interurban roads being, as they should be, in a class by themselves.

Without seeking to enter into the details of the peculiarities distinguishing each group of cases, much less those of the individual cases cited in illustration of particular facts, some of the general conclusions reached by the author may be briefly adverted to. He points out that the majority of roads in localities of less than 25,000 inhabitants have been capitalized at figures much in excess of the present cost of duplicating their tangible assets, and hence that they will frequently fail to permanently earn the interest on their mortgage indebtedness. As investments, none of them are regarded as worthy of consideration by other than local capitalists, who are able to give personal time and care to the management of the properties. The systems throughout the United States falling within this category number nearly 400. The author expresses the opinion, which seems to be amply justified by the figures of his table, that in cities of from 25,000 to 35,000, and from that up to 50,000 inhabitants, with systems constructed according to the best engineering practice of to-day, an electric line can rarely be operated for less than from 70 to 75 per cent. of the gross passenger income. A construction and equipment cost of $12.50 to $15 per capita of population served, is regarded as the highest amount that can be regarded as safe in communities of this size. For example, a 12-mile system in a town of 30,000 can be built for $250,000 at current prices, and ought to be able to earn $75,000 gross and $18,750 net per annum. The return on the investment would therefore be about 7.5 per cent. which, according to the author, is roughly the average intrinsic earning capacity of this class of properties. In larger communities, up to those of say, 100,000 inhabitants, the same considerations apply, although the increasing gross earnings per mile of track without materially greater first cost, make it possible in many instances to earn from 10 to 15 per cent. net on the actual value of tangible assets. In cities of from 100,000 to 500,000 inhabitants, in which the magnitude of the interests involved insure the continued employment of the best obtainable managing ability, a net earning power of from $2.75 to $3.50 per capita is not an unreasonable estimate. The actual cash cost of building and equiping a new system in these cities will rarely be less than $50,000 per mile of track, so that while liabilities of from $15 to $25 per capita are not excessive, larger amounts may well be regarded with suspicion. Most of the interurban systems reported in the tables appear to be very good properties, although the author points out that many schemes of this kind of very doubtful value are being urged upon capitalists in more recent days.

If the deductions of the author in reference to the admissible capitalization of street railways per capita of population served are anywhere near correct, and it certainly does not look as if they were unnecessarily conservative, there would seem to be abundant reason for uneasiness in financial circles as to the safety of the vast sums of money which have been diverted into this field of investment during the past five years. A table published in the *Street Railway Journal* of July, 1895, presumably compiled by Mr. Higgins from later returns than those embodied in the work under review, reveals some tendencies of street-railway financiering which are, to say the least, somewhat startling. While the capital liabilities in the state of Massachusetts, amount to no more than $56,300 per mile of track, which, under the conditions there prevailing, perhaps cannot be regarded as excessive, those in Rhode Island are put at $146,800, New York, $207,100, and New Jersey, $129,400. The average of all the roads in the United States, good, bad, and indifferent, is no less than $95,600 per mile of track, an amount which must be certainly three or four times the actual value of the tangible assets. Of course, it is obvious that in a business in which the operating expenses amount to something like 75 per cent. of the gross-earnings, such an extensive inflation as that above indicated cannot but ultimately bring about disastrous results. In setting forth the conditions which determine the profitableness or the reverse, of a street-railway system, and in giving information which shall enable the ordinary investor to distinguish the good from the bad, we think Mr. Higgins has performed a notable service to the public; a service which, moreover, has fortunately been rendered in good season, inasmuch as there is good reason to believe that a large proportion of the securities heretofore issued upon the class of properties under consideration have not yet come into the hands of the ultimate small investor, but still remain in more or less speculative channels, awaiting more favorable conditions for marketing than those which have prevailed for the past two or three years. The new stock issues, few of which represent actual cash investment, are chiefly held by promoters, "syndicates" and "traction-companies," as a source of future rather than present profits. The grave question is, to what extent has there been an actual over-capitalization of earning power, necessitating ultimate reorganization and a ruthless scaling down of nominal values? The information given in this work will in many cases, enable the intending or actual investor to determine this point for himself, in respect to any particular system.

Although it is scarcely six months since this work was written, the rapid progress of events has thrown much new light on the condition of some of the particular properties discussed by the author, and hence it is much to be hoped that the present edition may meet with sufficient appreciation and favor to encourage the author to prepare a revised and extended edition at no distant day.

F. L. P.

MORE PRAISE FOR THE "DATA SHEETS."

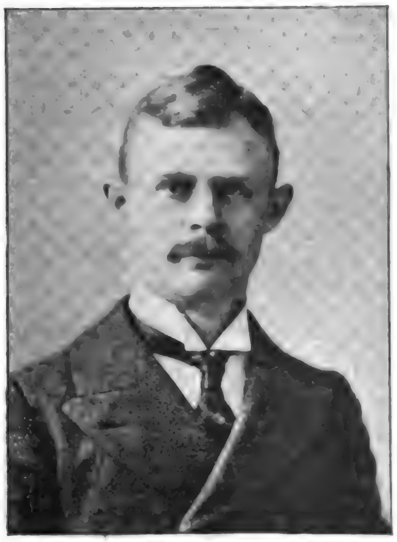
Will N. Eichberg, Superintendent Mutual Light & Power Co., Chicago, Ill., says: "I consider your 'Data Sheets' of the greatest value to all in the business, and would take one years to accumulate the same." Chas. Timberlake, with the Indianapolis Electric Co., telephone manufacturers, remarks: "I think it is a good thing."

THE TROLLEY IN BERLIN.

The Municipal Council of Berlin, Germany, have sanctioned the building of a trolley road and have specified the Thomson-Houston system to be used. The line to be equipped is part of the Grosse Berliner Pferdeisenbahn Gesellschaft, and the work will be done by the Union Elektricitäts-Gesellschaft of Berlin, who are the agents for the Thomson-Houston apparatus.

PERSONAL.

H. T. EDGAR.



Harry T. Edgar.

It may be doubted whether any younger man than Mr. Harry T. Edgar has ever been made general manager of a large electric light company, in a leading city. Mr. Edgar was appointed general manager of the Georgia Electric Light Co. of Atlanta, Ga., on Jan. 1, 1893, and became secretary and general manager in 1894. He was born in New Jersey in 1869, was educated at New Brunswick, N. J., and began work in the electrical field at the Edison station in that city, under Mr. Wilson S. Howell as superintendent. In 1886 he joined the Engineering Department of the Edison Electric Light Co. of which Mr. J. H. Vail was then general superintendent. He was transferred to the various similar departments of the Edison United Mfg. Co., the Edison General Electric Co. and the General Electric Co., enjoying opportunities for a singularly large and wide experience. He was a meter expert for the Edison Electric Light Co. and installed chemical meters in New Orleans, Erie, Pa., Easton, Pa., Scranton, Pa., Canton and Dayton, O., Winnipeg, Man., and Toronto, Can. In New York City he was employed for two years on the local Edison underground system; and he also installed the meter system and built the boards for Cincinnati and Milwaukee. Another important branch of work intrusted to him was that of making a technical canvass of the cities of Omaha, Sioux City and Buffalo, with a view to the introduction of the Edison system. It was as a result of all this work, faithfully and intelligently done, that Mr. Edgar was selected for Atlanta.

A few words as to the station under Mr. Edgar's care will not be out of place. The plant of the Georgia Electric Light Company consists of two McIntosh and Seymour engines 500 H. P. each, one Harris-Corliss 700 H. P., one Greene 900 H. P., and one Armington & Sims 125 H. P. engine; total 2,725 H. P. There are 19-50 light arc dynamos, T. H., 2-125 light arc dynamos, Wood, 3-2000 light alternators, 1-1300 light alternator, 1-1000 light alternator, 2 M. P. 100 K. W. power, 1 M. P. 200 K. W. power. The plant, in addition, furnishes power to the Atlanta Consolidated Street Railway Company from 4 M. P. 80 K. W. power generators; and has a contract for power with the Atlanta Electric Railway Company. The company is operating 625-2000 C. P. street arc lamps, 560-75 C. P. street incandescent lamps, 90 commercial arc lamps, 125 alternating arc lamps, 14,000 incandescent lights, and 500 horse power in motors. It has just bought one new 800 H. P. cross compound Greene engine and one 9,000 light alternating current machine from the General Electric Company. It expects to have same installed and running by November 15th. The company has orders on its books to wire for 2,500 additional lights.

Mr. Ernest Thurnauer, the well-known manager of the French Thomson-Houston Co., is again a visitor to the States. Mr. Thurnauer's stay on this occasion is a short one, as he is seeking rest and recreation in a trip around the world. We can only hope that Mr. Thurnauer will be everywhere received with that open hearted hospitality which he lavishes on all who have the good fortune to meet him in Paris.

Mr George K. Hooper, for three years agent and engineer of the Abendroth & Root Mfg. Co., has resigned, to accept a responsible position with the Deering Harvester Co., of Chicago.

Dr. Leonard Paget, late electrician and chemist of the Electric Power Storage Co., has severed his connection with that company and will now devote his attention to electrical contracting work and to all matters relating to electro-chemistry and electro metallurgy, in both branches of which he has had an extended experience. His offices are at 166 Elm St., New York.

LEGAL NOTES.

A BRIEF HISTORY OF THE DOUBLE CARBON LAMP LITIGATION.

In view of the recent decision on double carbon lamps, in Chicago, by Judge Showalter, in favor of the Western Electric Co. in the suit brought against it by the Brush Electric Co., it may not be inopportune to give a brief recapitulation of the history of double lamp infringement suits.

The first suit brought upon the Brush double carbon lamp patent No. 219,208, was that against the Fort Wayne Jenney Company upon the Cain lamp, which was then manufactured by the Fort Wayne Company. This suit was decided in the latter part of 1889, and was begun, we believe, in 1886 or early in 1887. A decision in favor of the complainant was rendered by Judge Gresham at Indianapolis, the only defense in this case being the invalidity of the patent. Infringement was practically admitted. Suit was also brought against a user of the Indianapolis Jenney Electric Company's double carbon lamp, which was also practically admitted an infringement, and as a matter of course a decision was reached in favor of the complainant.

In 1887, suit was begun against the Western Electric Light Company, of Toledo, Ohio, which used the Scribner lamp manufactured by the Western Electric Company, under patent No. 418,758. Here an entirely new question was brought up, but the Court notwithstanding reached a decision finding the defendant's lamp to infringe. This was in August, 1890. Prior to that time suit had been begun in the Northern District of Illinois against the Western Electric Company, and upon the finding of the Court in the suit at Toledo, Judge Gresham granted a preliminary injunction upon this same Scribner lamp which had been found to infringe in the Toledo case.

In getting the Brush double carbon lamp patent sustained, the Brush Company's counsel and experts had limited the claims to a single lamp controlling two sets of carbons. After the decision in the Toledo case, and after Judge Gresham had granted a preliminary injunction in the suit against the Western Electric Company in Chicago, the Western Electric Company began the manufacture of double lamps which, instead of being single lamps each controlling two sets of carbons, were two separate lamps enclosed in one case, each separate lamp controlling one set of carbons. The Brush Electric Company attempted to get a judgment of infringement against these devices by making a motion for attachment for contempt of court. This motion was made and argued before Judges Gresham and Blodgett in February, 1891, and denied. After this motion for attachment for contempt of court had been dismissed, a new bill was filed by the Brush Electric Company against the Western Electric Company upon the two forms of lamp above described, in which each set of carbons was controlled by a separate electro magnetic mechanism; and the proofs in the two cases, the one involving the original lamp which had been adjudged to infringe at Toledo and the other involving the so-called twin lamp above described, have been proceeding for the four or five years since that time. The two cases were finally brought to hearing on May 1st last, and resulted in the decision of Judge Showalter limiting the Brush patent and finding that neither the original Scribner lamp involved in the Toledo case nor the twin-lamp involved in the subsequent suit, infringed the Brush patent.

The Brush Electric Company has filed bills against a large number of users of double carbon lamps, which, however, have not yet been brought to trial. There are some fifteen or more of these cases, some of them municipalities in various parts of the country.

Other litigation against other manufacturers of double carbon lamps has been proceeded with in other circuits, and in some instances settlements have been made, the defendants being influenced thereto by the opinions of the courts in the various cases which had been contested. The Brush double carbon lamp patent expires September 2, 1896.

A RESULT OF THE PENNSYLVANIA TROLLEY DECISION.

A curious and natural result of a recent decision of the Supreme Court with regard to electric railways was shown in the case of one of the suburban lines of Philadelphia. The line was built, but the Supreme Court, having decided that electric railways could not be constructed without the consent of all the property owners adjoining, five property owners in a stretch of 12 miles have objected and prevented the operation of the road. In this dilemma the managers have purchased dummy steam cars, and are going to operate it in that way. This method is cumbersome and most objectionable, furnishing the minimum accommodation with the maximum of nuisance, and yet, under the decision of the Supreme Court, it is perfectly legal to run the noisy, clumsy dummies, with or without the consent of property owners, while cleanly, handsomely equipped, swift electric cars cannot be moved over the line until the last objector withdraws his opposition.—*Reading, Pa., Herald.*

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JULY 30, 1895.

Accumulators:—

Secondary Voltaic Battery, L. Epstein, London, Eng., 543,680. Filed Jan. 5, 1895.

A negative plate made of wire gauze electrolytically coated with zinc, positive plates inserted between the negative plates, and revolving agitators of insulating material interposed between the opposed surfaces of the positive and negative plates.

Alarms and Signals:—

Railway Signalling System, T. B. Dixon, Henderson, Ky., 543,591. Filed November 17, 1893.

Electrical Railway Signalling System, T. B. Dixon, Henderson, Ky., 543,592. Filed October 5, 1893.

Register, T. B. Dixon, Henderson, Ky., 543,593. Filed February 14, 1894.

Relates to that class of registers which are used in connection with automatic railway block-signal systems to register each wheel of a train as it passes into the block, and to cancel the record as the wheel passes out of the block.

Electrical Railway Signalling System, T. B. Dixon, Henderson, Ky., 543,594. Filed July 10, 1894.

Electrical Railway Signalling System, T. B. Dixon, Henderson, Ky., 543,595. Filed August 20, 1894.

Electrical Railway Signalling System, T. B. Dixon, Henderson, Ky., 543,596. Filed August 20, 1894.

Track Instrument, T. B. Dixon, Henderson, Ky., 543,597. Filed August 20, 1894.

Relates to a signalling system.

Signalling on Railways and Means Therefor, Edwin Blakey, Bradford, Eng., 543,721. Filed June 11, 1894.

Designed to be employed in conjunction with the ordinary single needle block system.

Railway Signalling, J. G. Schreuder, Edgewood Park, Pa., 543,785. Filed March 28, 1894.

Switch and Signal Mechanism, J. V. Young, Boston, Mass., 543,798. Filed August 29, 1894.

Distribution:—

Manhole for Underground Conduits, J. F. Cummings, Detroit, Mich., 543,613. Filed November 6, 1894.

Details of construction to afford safe and convenient connections.

Dynamos and Motors:—

Starting or Stopping Device for Electric Motors, J. P. B. Fiske, Alliance, Ohio, 543,523. Filed November 14, 1894.

The torque of the movable field magnet frame automatically operates a shoe, and causes it to pass over the contacts of the rheostat.

Device for Automatically Operating Brakes and Rheostats, J. P. B. Fiske, Alliance, Ohio, 543,524. Filed December 6, 1894.

Similar to above.

Electric Motor and Brake Mechanism Therefor, J. P. B. Fiske, Alliance, Ohio, 543,525. Filed February 9, 1895.

The counter torque of the field is utilized to operate a brake.

Electrometallurgy:—

Process of and Apparatus for Treatment of Precious Metals, Edwin J. Fraser, San Francisco, Cal., 543,546. Filed Nov. 25, 1893.

Process of Extracting Precious Metals from Their Ores, M. Crawford, Colorado Springs, Colo., 543,673. Filed October 29, 1894.

Consists in exposing a cyanide solution to the action of an electric current in the region of the anode only, until considerable portion of said solution is converted into cyanate by electrolytic action, and employing said solution as an agent for lixiviating the ore.

Process of Extracting Precious Metals from Their Ores, M. Crawford, Colorado Springs, Colo., 543,674. Filed December 8, 1894.

Similar to the above.

Apparatus for Extracting Precious Metals from Their Ores, M. Crawford, Colorado Springs, Colo., 543,675. Filed December 14, 1894.

Relates to above.

Electrodeposition of Alloy, H. J. Altman, New York, N. Y., 543,824. Filed April 12, 1894.

Consists in forming a bath or solution containing a chloride of platinum and the sulphate of the other metal, and an anode composed of an alloy of the metals to be electrodeposited.

Lamps and Appurtenances:—

Electric Arc Lamp, S. E. Nutting, Chicago, Ill., 543,502. Filed April 5, 1894.

A constant potential alternating current lamp. The magnet and armature are so related that the induced counter electromotive force of the magnet varies with the changes of position of the armature.

Electric Arc Lamp, C. E. Harthan, Lynn, Mass., 543,729. Filed November 21, 1894.

A spring is arranged to progressively assist the action of the core when the arc is first struck. Intended for alternating arc lamps.

Miscellaneous:—

Electrical Controlling System for Elevators, C. O. Mailloux, New York, N. Y., 543,495. Filed May 28, 1895.

Arranged so that it is impossible for any one to run the car so long as any of the landing doors are open or to open any of the doors so long as the car is running. No one can obtain control of the car while it is being operated by another.

Reactive Coil, E. E. Stark, New York, N. Y., 543,564. Filed February 21, 1894.

Details of construction

Internal Illuminator and Probe, W. E. Dow, Braintree, Mass., 543,616. Filed February 16, 1895.

Electric Soldering Iron, F. B. Rae, Detroit, Mich., 543,654. Filed September 18, 1894.

An electric soldering iron for cans, etc., comprising a fixed standard or rod, upon which the soldering iron is pivoted and turns, with means for revolving it about the fixed standard in the circular path.

Electric Clock Winding Mechanism, W. E. Scales, Everett, Mass., 543,707. Filed November 12, 1894.

Hot Box Indicator for Railway Cars, Lyndon, Athens, Ga., 543,743. Filed December 13, 1894

A mercury thermostat arrangement.

Electric Heating Rug, J. R. Davis, Parkersburg, W. Va., 543,800. Filed July 11, 1894.

Watchman's Time Recorder, George F. Ransom, Milwaukee, Wis., 543,655. Filed Sept. 4, 1894.

Elevator, Norton P. Otis, Yonkers, N. Y., 543,680. Filed March 2, 1893.

Overhead Travelling Crane, Thomas R. Morgan, Sr., Alliance, Ohio, 543,557. Filed Sept. 10, 1894.

Railways and Appliances:

Electric Brake, W. B. Potter, Schenectady, N. Y., 543,851. Filed March 23, 1895.

Couples the cars so that by the rupture of the coupling a circuit will be completed through the brake magnets upon the portion of the train separated from the motors.

Electric-Brake Shoe, William B. Potter, Schenectady, N. Y., 543,653. Filed March 30, 1895.

Electric-Car Brake, George B. Damon, Lowell, Mass., 543,544. Filed April 9, 1894

Electric Trolley, G. W. Hooper, Rochester, N. Y., 543,539. Filed September 11, 1894

Four-Motor Reversing Switch, F. E. Case, Schenectady, N. Y., 543,670. Filed May 15, 1895

Improvement on patent No. 524,396. Intended for electric cars.

Telephones:—

Signalling Apparatus for Telephone Exchange Circuits, J. J. O'Connell, Chicago, Ill., 543,559. Filed May 14, 1895.

A clearing out signal, consisting of an incandescent lamp, which lights up and extinguishes.

Transmitting and Receiving Attachment for Telephones, H. W. Libbey, Boston, Mass., 543,626. Filed October 9, 1894

Telephone Exchange, W. Y. Shibata, San Francisco, Cal., 543,708. Filed November 24, 1893.

Details relating to an automatic exchange.

Telephone, N. L. Burchell, Washington, D. C., 543,798. Filed October 29, 1894.

The arrangement is such that the carbon granules are agitated whenever the instrument is used.

AUTOMATIC BASEBALL BY ELECTRICITY.

One of the most ingenious and interesting of the recent applications of electricity is its use in the reproduction on the stage of a theatre exactly as played at the same time on the regular grounds, of a baseball game between any two of the National teams contesting for the pennant. Curious as it must seem to all steady playgoers, the first series of performances of this character is now being given on the classic boards of Palmer's Theatre, this city; but while the thing strikes one at first as rather curious, it is certain that heartier applause could not possibly greet any "legitimate" production. "Automatic Baseball by Electricity" is the invention of Mr. Frank M. Chapman, long time connected with Mr. Joseph Jefferson's Company, and his three financial associates are the three sons of the famous actor, Thomas, Charles and Joseph, who are giving the inventor also their active co-operation in matters of management and detail.

The whole stage at Palmer's is set out as a baseball field, with green baize turf and a strictly accurate "diamond," whose only novelty is that it abounds in vampire traps, through which the players disappear when put out, instead of returning to the bench with dust on their clothes and loud protests on their lips. This innovation is a decided improvement. The path of the diamond from base to base is grooved, for travel, and the spot for the catcher is also grooved in order that he may close in after two "strikes." All the players have their proper positions on the big field, and are represented by dummy marionettes, true to the life and about 3 feet high. Besides the fielding team, and the man at the bat or those on bases, three men of the in team are seen on a bench waiting their turn; two coaches gesticulate wildly on right and left field, and back of the pitcher's box is an umpire who calls game and waves his arms quite à la mode. Moreover the batter at the home plate is provided with a bat which he flings down with a genuinely "sickening thud" when he starts for first base. Around the field is a drop representing a big fence, with the usual advertisements, and at the wings is the grand stand of which the real spectators in front are supposed to be occupying a portion. The field is sloped gently upward so that it is in full view. Along the footlight edge runs a scoring board, which gives the figures not only of the game in progress but of the other League contests.

But where is the ball? The answer to this discloses Mr. Chapman's further ingenuity, which is of a very high order. Each fielder, including pitcher and catcher, has a white incandescent lamp in his hand, which lights up only when he has the ball, so that one always sees and knows where the ball is. When it leaves the pitcher's hand, his white light goes out and the white light is seen in the catcher's hand. If the pitcher's hands are above his head, it is "one ball." If the light shows with his hands at his waist it is a strike. If the batsman hits the ball foul, it is shown within the foul line by a green light at the spot. If the batsman does his duty, and hits the ball plumply, its track across the sward is shown by a series of white lights bursting into momentary gleams one after the other across the baize. If the ball is a "fly," its course through the air is marked by a series of white lights strung from the flies. If a fly drops safely in a fielder's hands, his white light breaks forth boldly. If he fumbles, the light flickers, and when the ball drops a red light shows at his feet, indicating the "error." It will be readily understood that a batter can thus be followed around the diamond until his course is stopped by the white light breaking forth in the fielder's hands at the base he is striving to reach. If he gets there safely, the light goes out. If he is too late, the light stays, and he can realize to the eye the wish that the earth would open and swallow him. Each batsman follows the grooved track on wheels which

move his legs so that he seems to be running, and of course he can be seen in the very act of trying to steal the next base.

Nor is this all. The umpire has a white light, so that when a ball is hit out of play, he is seen to furnish a new one which, of course, shows up in the hands of the pitcher just as quickly as the circuit can be switched. The actual movements seen on the field are supplemented by the work of an elocutionist who repeats the messages coming directly from the game and received by an ordinary sounder set. It is no exaggeration to say that one sees or feels the whole game, except the rows with the umpire—which are not part of the game and can well be dispensed with.

The whole process is governed and operated from a simple central switchboard in the wings, and supplemented by two large billboards at the side of the game, giving a list of the players and their positions. By means of a series of multi-point switches and snap push buttons, all the lights are flashed and all the movements are indicated; the same means also serving to change the color of the teams at the close of each inning. At the present time, Mr. Chapman has his men on bases and the catcher manipulated by boys under the baize field, to whom he signals by concealed flash-light code; but he has worked out the whole method of automatically moving each figure by electric motor. The regular street lighting 110 volt circuit is used on all the lamps, with the utmost ease. The switching and control board is not three feet square, and can be carried comfortably by one man, so that the governing mechanism has evidently been reduced to a minimum. The umpire and coachers are also moved by strings so as to go through actions that are natural. All told, 50 incandescent lamps are used in the game.

The prices of admission to this spirited and really exciting electric pantomime are only 25 and 15 cents, and we heartily recommend our readers to take in the show, whether baseball cranks or merely electrical enthusiasts. They will be well repaid for their time and trouble, and will see in operation an invention which is so clever and full of applicability, it cannot stop short even at the thrilling simultaneous reproduction of the National Game. We are glad to note that the show has been drawing large crowds.

TERMS AND CONDITIONS OF THE HORSELESS VEHICLE RACE, CHICAGO TO MILWAUKEE.

We give below, in response to a great many inquiries, the full terms and conditions of the great horseless vehicle race, organized for next November by the *Chicago Times-Herald*:

First prize—$2,000 and a gold medal, the same being open to competition to the world.

Second prize -$1,500, with a stipulation that in the event the first prize is awarded to a vehicle of foreign invention or manufacture, this prize shall go the most successful American competitor.

Third prize—$1,000.

Fourth prize—$500.

The third and fourth prizes are open to all competitors, foreign and American.

It must not be supposed that in this contest the question of speed is the only requisite to be considered. It would be possible for an ingenious mechanic to construct a machine with which he could easily outstrip all others in this contest, and yet that device would be of no utility and the outcome of no value to the world from a practical point of view.

It is the earnest desire of the paper that this contest shall add to the sum of our mechanical knowledge in this, the new branch of the science of transportation. In this spirit the following rules are laid down for the guidance of all who may desire to enter into the competition:

1. The date of the contest will be Saturday, Nov. 2, 1895. The judges may postpone the contest if in their judgment the state of the weather or the condition of the roads will not permit a fair trial.

2. The contestants will start at some point in or near the City of Milwaukee and will finish at some point in or near Chicago, not farther south than the south limit of Lincoln Park.

3. The contest is limited to automatic carriages, or, as they are more commonly known, "horseless carriages." There will be eligible to competition any and all vehicles having three or more running wheels, and which derive all their motive power from within themselves. No vehicle shall be admitted to competition which depends in any way upon muscular exertion, except for purposes of guidance. Competing vehicles which derive their power from petroleum, gasoline, electricity or steam, and which are provided with receptacles for storing or holding the same, will be permitted to replenish the same at Waukegan, Ill., and at Kenosha, Wis., but at no other points.

4. No vehicle shall be admitted to competition unless it shall comfortably carry not less than two persons for the entire distance, one of whom may have charge of the vehicle and the manipulation of the same.

5. No vehicle shall be admitted to competition except that it be free from danger, not only to its occupants but to spectators and the public users of the highway. The judges at their discretion may debar any vehicle which from its construction gives evidence of defects which would render the adoption of its type an evident impossibility.

6. For the purpose of limiting the contest to vehicles of practical utility a preliminary test of all vehicles entered for competition shall be held by the judges on or about Saturday, Oct. 26, under such rules as the judges may determine on, and for such a distance as they may decide. At this test the judges may debar such constructions as in their opinion do not possess features entitling them to further consideration. It is stipulated, however, that all motor vehicles which won prizes or honorable mention in the Paris-Rouen contest of 1894 or in the recent race between Paris and Bordeaux shall not be compelled to compete in the preliminary test, but shall be admitted upon proper application to the final competition on Nov. 2.

7. In making awards the judges will carefully consider the various points of excellence as displayed by the respective vehicles, and so far as possible select as prize winners those constructions which combine in the highest degree the following features and requisites, rating them of value in the order named:

A. General utility, ease of control and adaptability to the various forms of work which may be demanded of a vehicle motor. In other words, the construction which is in every way the most practical.

B. Speed

C. Cost, which includes the original expense of the motor, and its connecting mechanism, and the probable annual item of repairs.

D. Economy of operation, in which shall be taken into consideration the average cost per mile of the power required at the various speeds which may be developed.

E. General appearance and excellence of design. While it is desired that competing vehicles present as neat and elegant an appearance as possible, it should be assumed that any skilled carriage-maker can surround a practical motor with a beautiful and even luxurious frame.

8. All vehicles must be entered for competition not later than Sept. 15, 1895. All applications should be addressed "Editor Horseless Carriage Contest, Room 511 Times-Herald Building."

The date of the contest will not be changed from Saturday, Nov. 2, except for extremely bad weather or condition of the roads.

In answer to many inquiries as to how the carriages will be started it may be assumed that the judges will start them one or two at a time, keeping accurate record of the exact time each carriage passes the starting point, the same as is the rule in a yacht race. The various vehicles will be designated by numbers conspicuously displayed and a record will be kept of the time at which they pass various points along the road. Other less important rules will be formulated and officially announced by the judges at the proper time.

While two persons are fixed as the minimum number of passengers carried, the judges will undoubtedly take into consideration the handicap imposed on vehicles conveying a greater number.

MANUFACTURING ELECTRIC MEN AT TONAWANDA, N. Y.

And now Niagara Falls will probably be the location of a factory for turning out electric men; not mesmerists or svengalis, but automatons that will run by electricity. They have built one up at Tonawanda at the Gillie, Goddard & Co.'s plant where they turn out merry-go-rounds. This man has been on the streets of that town. It is an invention of Philip Perew, who has secured a patent. The idea is by no means perfected. At present all the man is good for is to pull a cart about the streets of a city. The model that has been exhibited in Tonawanda to the delight of the populace and the honor of a certain soap is but a crude thing. The man clothed in continental uniform drags a heavy cart with some ease, while on the sides of the cart flaring signs exalt the glory of soap or pills, as the case may be. The model has been on the streets of Tonawanda, and it worked well. It was so alluring that the small boy flocked in such dense swarms that the policeman was summoned to chase him away. The man was about seven feet tall, and was modeled after William F. Sheehan. The cerulean of its eyes matches that of its famous counterpart exactly. The men, though, that the firm will make will be run by storage batteries, and have a phonograph. The phonograph can say whatever is desired. It can expound the virtues of patent medicine or be used for political campaigns. So, at present, the only form of labor threatened by the invention is that of the sandwich man and that of the campaign speaker. The men and carts that are used to extol medicines will be very fine pieces of mechanism, and can be geared to go as fast as anyone desires. By simply turning on a current, the man, his eyes still fixed on eternity, can hump down the street at a rate far exceeding any bicycle. The limit has not been reached. In course of time it may be that men can be constructed to do almost anything, and the laboring-man can sit around and smoke 25 cent cigars while a multitude of electric men do all the work. This will not occur for some years yet, but, no one can say where it will stop.—*Niagara Falls N. Y. Gazette.*

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

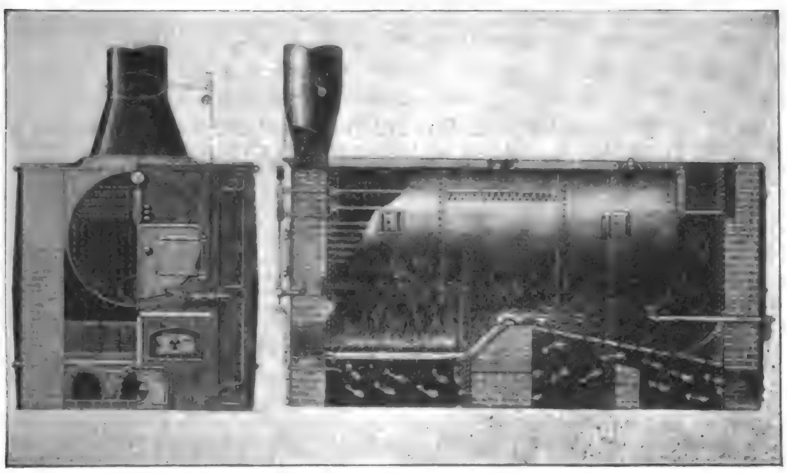
THE WEITMYER STEAM BOILER FURNACE.

We have received from the Harrisburg Foundry and Machine Works, of Harrisburg, Pa., a neat little catalogue descriptive of the Weitmyer steam boiler furnace, manufactured by them. The furnace can be applied to existing boiler setting without expensive changing, and is claimed to reduce the expenditure of fuel at least 15 per cent. The appliance is inexpensive and simple and gives almost perfect combustion.

As the accompanying engraving shows, its arrangement is such that all air for combustion is taken in at the rear of the setting and under the flame-bed, and thus, becoming heated before being introduced to the furnace, aids combustion and also prevents the chilling of the boiler, which occurs when the draft is taken at the front end.

A portion of the heated air, after passing through the bridge wall arches into the ash pit, and is allowed to pass to the top of the bridge-wall through suitable passages. It is this air which supplies the necessary oxygen to ignite the gases, the very pith of the fuel, which would otherwise escape unconsumed. In addition to the stated economy of 15 to 20 per cent. in fuel, an inferior grade of coal can be advantageously used; although the setting does not insure the consumption of dirt. This furnace is highly spoken of in letters from a large number of manufacturing firms, who are unanimous on the score of its economy and easy firing

At a test of the steam plant of the New Bedford and Fair Haven Traction Company, New Bedford, Mass., for the determination of working conditions and economy, the following results were obtained: Engine: Harrisburg "Ideal" tandem compound, 14 and 24 x 16 in.; indicated average horse power, 170 95; pounds of water per pound of coal, 12.19; pounds of water from and at 212°, 13.12. This shows remarkably high evaporation per pound of fuel.



The Weitmyer Steam Boiler Furnace.

THE MICHIGAN ELECTRIC CO. TO REPRESENT GENERAL ELECTRIC.

The Michigan Electric Company, of Detroit. Michigan, has recently completed an arrangement with the General Electric Company, and the Edison Illuminating Company, of Detroit, covering the selling agency of General Electric machinery and supplies in Michigan. This arrangement covers the entire line of General Electric manufactures, including lighting generators, motors, incandescent lamps, and all their various lines of machinery and supplies.

The Michigan Company which was incorporated about two and a half years since has during that period grown rapidly, and today has one of the largest and best equipped supply houses in the country, and is making itself felt as a strong competitor for the supply business.

The Michigan Company has, however, made an exception in the matter of overhead railway material in which line it will continue to manufacture and sell the "Michigan" hangers, etc. which have obtained a most satisfactory recognition among the street railway companies. The Michigan Company has recently engaged Mr. H. E. Baldwin, formerly representing the General Electric Company in Kansas, Missouri, and Oklahoma, who will look after the State trade, and Mr. L. J. Baldwin will hereafter be in charge of the sales at the Company's headquarters.

PROPERTY OWNERS AS STOCKHOLDERS AT ORANGE, N. J.

The recently-organized Freeman Street Improvement Company of Orange Valley, proposes to improve the street, and incidentally to build a trolley road from the Highland Avenue Station of the Morris and Essex Railroad, in a stright line, through Freeman Street, up the side of the Orange Mountain, with a temporary terminus at St. Cloud.

The capital stock of the new company is placed at $100,000, and all the stockholders will be property owners along the line of Freeman Street, no other persons to be eligible for membership in the corporation, and the stock to be divided on a pro rata basis, according to the benefit conferred in building the road. The incorporators of the company are Victor N. Savale, Christian H. Heckel, J. Henry Fieldler, and John J. Barry, and the officers are: President—John Davis; Vice President—Frans Berg; Secretary and Treasurer—Robert D. Colins.

ADAMS MOTOR AND STURTEVANT BLOWER.

We illustrate in the accompanying engraving a direct connected electric motor designed by Mr. Alton D. Adams, and a steel pressure blower built by B. F. Sturtevant Co., both of Boston.

The motor delivers 4 H. P. at a speed of 500 R. P. M. to a 60 inch blower, the blast wheel being mounted on the extended armature shaft. This motor explodes the idea that slow speed at moderate cost can only be attained by means of multipolar magnets and toothed armatures, as its field magnet is of the bipolar, forged iron type and its armature has a smooth core, while the total weight of the machine is only about 600 lbs.

Adams Motor and Sturtevant Blower.

A large number of machines of the above type have been designed for general and special purposes and have proved very economical to build and satisfactory in operation. Mr. Adams makes a specialty of the design of electrical machinery for manufacturers, particularly when unusual or exacting conditions are to be met.

NEW YORK NOTES.

Noll & Sibley, of the Postal Telegraph Building, have dissolved partnership, Mr. Noll retiring from the firm to engage in another line. The business will be conducted as before, at the same office, under the firm name of C. C. Sibley & Co.

Newburgh, N. Y.—The Edison Electric Light Company of this city has been consolidated with the opposition company, the Newburgh Electric Light and Power Company. The agreement includes the capitalization of the new company at $350,000. It is to be known as the Consolidated Gas, Electric Light, Heat, and Power Company of Newburgh.

Ford & Bacon, the electrical and mechanical engineers, of 208 Broadway, New York, have taken into partnership Mr. G. H. Davis, M. E., well known in the electric railway field. He is now in New Orleans in connection with the important railway work that the firm has in hand there. In addition to their New York office, and that at 421 Chestnut street, Philadelphia, the firm have now opened an office at 106 Camp street, New Orleans.

"THE AMERICAN FLAG."

The Electric Appliance Company report something startling in the dry battery line, having taken the General Western Agency for the American Flag dry battery.

The American Flag is claimed to be a decided step in advance in the manufacture of dry batteries, and is claimed to be superior in the volume of current and staying powers to the best open circuit batteries wet or dry. For telephone work it is said to be without an equal and is being extensively used. It is made in three sizes, filling the demand for a small pony battery or for a cell of extra large volume.

"A VERY HANDY THING."

Mr. E. T. Pardee, Mgr. Fort Wayne Electric Corporation, Omaha, Neb., writes: "Enclosed find 60 cents in stamps for which please mail me a morocco filing case for the Data Sheets. They are a very handy thing."

SALES OF GOULDS POWER PUMPS.

The Goulds Mfg. Co., Seneca Falls, N. Y., report the following sales of their Power Pumps: Archibald Rogers, Hyde Park on Hudson, N. Y.—one 8½" x 4" triplex pump for water supply. Capital Electric Light, Motor & Gas Co., Boise, Idaho,—one 1¾" x 2½" triplex pump for water supply. F. S. Blackhall, New York, —one ¾" x 2½" triplex pump for water supply. N. O. Railway & Mill Supply Co., New Orleans, La.,—four 5" x 3" triplex pumps. These pumps are operated by electric motor direct geared, all being mounted on one bed plate.

BELKNAP MOTOR CO.

The Maine State College electric light plant contract has just been awarded the Belknap Motor Company of Portland. The entire plant when completed will embrace one 15 and one 30 K. W. generater and several motors. The grounds will be supplied with four arc lights and the buildings with some 350 incandescent lamps. The Belknap Motor Co. have also just been awarded the contract for the new Rumford Falls Sulphite Paper Mill Co. electric light plant, calling for one 300-light dynamo and 250 lights installed.

THE TROLLEY SYSTEM IN ST. LOUIS.

A special correspondence of the *Evening Post* says:—A street railway president in this city remarked to-day: "The general introduction of electricity as a motive power has brought the officers and men of the street roads into closer relation than that they sustained under the old system. The primary cause of this is that it takes a higher order of intelligence to manage a trolley than it does to drive a mule. We have regular schools of instruction now which the men must attend, and this has brought the best of them forward. Ability is quickly detected by the questions asked and the interest taken, and wherever ability is found it is marked for promotion. One result of the school of instruction is that it is steadily reducing the percentage of accidents, and we expect to get this average below the old average on horse-car lines. Under the régime of the trolley drink has been absolutely prohibited among employees, and the well-remembered mulewhacker, whose capacity for whiskey was only exceeded by his versatility in profanity, is of the past. He has been weeded out. It is an indisputable fact that a far better class apply for the position of motorman and conductor than were in the habit of seeking employment as driver or conductor. It is a sort of scientific job now, and not a few fare-collectors have by dint of study and observation become pretty well-informed electricians."

A mammoth generator and twin engines are being placed in the power-house of a local company. Mr. Scullin, Vice-President of the line, when asked if it was made necessary by increased traffic, said: "Not altogether. In the winter we expect to use it as a stove. We intend to heat all our cars by electricity in future, doing away with the unsatisfactory coal-stove altogether."

NEW YORK NOTES.

Mr. G. E. Emmons has become the general manager of the Schenectady works of the General Electric Co.

Mr. J. T. Hambay, the general manager of the Beacon Lamp Co., of Boston, was in New York last week making many arrangements for the new business of this progressive concern.

A. De Ronde & Co. are meeting with marked success with their imported "Ship" cored carbons. Inquiries and orders are coming in fast, and all users seem to appreciate their sterling worth. The "Ship" carbon gives a steady, brilliant and economical light, and all users of carbons should procure a sample and give them a trial.

Mr. James G. Biddle, of Philadelphia, was a caller at this office last week. He reports an excellent inquiry and increasing demand for the instruments, batteries and other specialties he is handling.

Mr. M. E Baird, of the Eddy Elec. Mfg. Co. was in New York last week attending to some important new contracts. Eddy motors and generators are in great demand, and the company is making another increase in wages on September 1.

Messrs. Warren S. Hill and F. A. Wyman were two good Bostonians who found their way into the Engineer office last week and gladdened it with a budget of gossip and scores of new ideas, each worth at least $10, on electrical subjects.

In our recent description of the Baltimore tunnel power plant it was stated that the two fans used were of the Sturtevant pressure pattern. It seems that this was a slight error and we have been requested to state that the entire mechanical draft system including the two fans was designed by Mr. G. C. Hawkins.

The Anchor Electric Co., of Boston, have opened a New York branch office in the Havemeyer Building, New York, room 1105, in charge of Mr. A. B. Field, who has been connected with this company since its organization, and who is widely known to the electrical trade.

The Gold Street Car Heating Co., has been formed with a capital stock of $200,000. The president of the Company is Mr. Edward E. Gold, the well known inventor of car heating apparatus. The company will shortly bring out a new electric heater designed by Mr. Gold, which is said to be 25 per cent. more economical than any thus far produced. The company also does car heating on the Gold hot-water-system, having last winter equipped 200 cars on the Third avenue surface road in New York City. The company's offices are located at Bridge Store No. 6, at the corner of Frankfort and Cliff streets, New York.

PHILADELPHIA NOTES.

Francis Bros. & Jellett, incorporated, have taken out a permit for the placing of boilers, engines and dynamos in Horticultural Hall, on South Broad street. The work to be done comprises a complete equipment for heating, lighting and ventilation according to the most approved modern methods and will cost $25,000. The same firm have also secured permit to place tubular boilers, engine and electric light plant in the store and light manufacturing concern at 324 Market street.

WESTERN NOTES.

Morrison, Ill.—The Whiteside Harrison Telephone Company of Whiteside County has been formed at Morrison; capital stock, $6,000; to construct a telephone plant with connections in other counties; incorporators, Aaron D. Hill, Simon S. Greider and John B. Hill.

Kokomo, Ind.—The American telephone manufactured by the Laclede Electrical Company in this city, will be used in Logansport after October 1. The common council of Logansport at their last meeting revoked the franchise of the Harrison company and granted a franchise to E. B. Overshimer, representing the American company. The rates will be $18 per annum for business houses and $12 for residences.

Mr. J. R. Wiley, Chicago manager of the Standard Underground Cable Co. of Pittsburgh, reports that he is kept hard at work, and that his well known company are very busy. Mr. Wiley was recently in some of the other Western cities, and states that in every place he visited the prospects for a large Fall business were plainly visible.

Mr. J. J. Gates, General Manager of the Perkins Electric Switch Co. of Hartford, Conn., has just paid a visit to Chicago for a few days, where he was warmly welcomed by his many friends, who would have liked him to stay longer amongst them. Mr. Gates expects some good business in the near future both from the home end, and the Western territory, which is well looked after by their representative, Mr. G. W. Conover.

The Bryant Electric Co. is at work upon a new catalogue which it will issue this fall. Thos. G. Grier and Edward R. Grier, managers of the western office, Chicago, are busy on some new devices which will be placed upon the market in the near future. The Bryant marine switch, the most recent of the Bryant Electric Company's products, is used upon the two great American steamships, the "St. Paul" and "St. Louis," and, like all of the Bryant specialties, is a good substantial article.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XX. AUGUST 14, 1895. No. 380.

COMMERCIAL PRODUCTS RESULTING FROM ACETYLENE—A NEW USE FOR THE ELECTRIC FURNACE.

BY

R. K. Duncan.

It occasionally happens that the easy synthesis of one chemical compound will unlock the door to the cheap commercial production of a room full of others. Such a statement finds exemplification in the recent remarkable production of the gas acetylene by heating merely a mixture of coal and lime (or charcoal and chalk) in an electric furnace, and throwing the resulting calcium carbide into water.

It is declared that calcium carbide (with water power to run the dynamos) may be made for less than twenty dollars per ton. Now from one ton of calcium carbide we may obtain 812 pounds of acetylene gas, costing less than two cents and a half per pound. This means, with certainty, the cheaper manufacture of innumerable substances used in the arts which may be made from acetylene by processes, which up to this time have been matters of pure chemistry, but which, on account of the lessened cost of acetylene, will now wage war with the older methods.

Acetylene, on being passed through an iron tube heated to dull redness, goes rapidly and completely into benzine, without the formation of any other product. Benzine is a product of prime importance, and is the base of thousands of organic substances, known as the benzine series of compounds. If the resulting benzine vapor be passed into strong nitric acid it is transformed into the oily nitro-benzine, and this, on treatment with hydrochloric acid and iron filings, goes easily into aniline. The ton of calcium carbide, or the 812 pounds of acetylene, results thus in somewhat less than 956 pounds of aniline. With the formation of aniline the road is now clear for the production of the innumerable dye substances whose varied hues have adorned the sisters and wives of the last twenty years, and whose discovery and preparation absorb the energies of an army of chemists.

Instead of passing into the dye substances, however, we may transform our aniline into carbolic acid. Thence it is but a step to picric acid, the foundation substance of many modern explosives. Or again, we may boil the aniline with acetic acid and we have transformed it into acetanilide or anti-febrin, the well-known fever specific. These substances, with their varied properties, come thus primarily from a lump of coal and a piece of lime.

Our protean acetylene, however, is capable of undergoing other changes just as startling. For instance, if it be passed through a tube heated to bright redness, it is changed to naphthalene, and naphthalene again will pass into a multitude of other valuable products. Or again, starting with acetylene, by the action of nascent hydrogen, we may change it into ethylene and finally into ethane. Ethylene, on being boiled with sulphuric acid and water successively, passes into alcohol, which is absolutely necessary to the production of an enormous number of economic substances. Ethylene on treatment with permanganate of potash readily oxidizes, first into oxalic acid, and then into formic acid. If the formic acid so obtained be treated with ammonia, and the resulting product heated to 180 degrees C., it is transformed into the deadly prussic acid. Acetylene in the mere presence of salts of mercucy unites readily with the elements of water to form aldehyde, so much used to-day in the production of essences and the manufacture of mirrors.

Starting with acetylene, by the agency of such cheap commercial products as muriatic acid, sulphuric acid, potash, ammonia, and a few others, it is possible to build up whole systems of dyes, medicines, essences, perfumes, poisons and explosives. The methods by which this may be accomplished are known matters of pure chemistry. They become commercially and economically practicable with the cheap synthesis of acetylene. Since this has been accomplished by the aid of the electric furnace and a mixture of lime and coal, we may expect to see the influence of acetylene ramifying throughout all organic chemistry. It has a utility out of all proportion greater than that derived from its peculiar light giving powers.

STORAGE BATTERIES IN TELEGRAPH WORK.

One is so prone to associate the storage battery with applications calling for heavy currents that one is apt to lose sight of a very important branch of electrical work in which cells of this character have proved of great usefulness. We refer to their use in telegraph, telephone, police and fire alarm and signalling work, in which fields they have already brought about little short of a revolution in the older methods. The advantages of a source of electric current other than the gravity battery were recognized as soon as the continuous current dynamo became a commercial actuality; and we need only recall the equipment of Siemens machines, which the Western Union installed in their New York main office as far back as 1876, to demonstrate the early appreciation of this fact.

Dynamo plants have been installed in a number of the larger central offices in the United States, but it must be evident that there are few places where it would pay to put in a generating plant for telegraph purposes alone. On the other hand, there are a large number of cities, whose telegraph business has heretofore required a large number of gravity cells, the original cost and the maintenance of which has always figured as a considerable item in the operation of the offices. If to this be added the fact that there are few, if any, cities in the United States below 5,000 inhabitants, which are not equipped with a central electric lighting station, it is apparent that a means is at hand for utilizing the storage battery as a substitute for the gravity cell. This fact is being gradually taken advantage of by the telegraph and railway companies doing large telegraph and signalling

work, with the result that we note a rapid increase in the employment of storage batteries.

A very simple calculation will show the advantages which the storage battery possesses for this purpose. Thus, if A = the voltage per cell of primary battery, B = the average working current, C = the cost of maintenance per cell (labor and material), then,

$$\frac{C \times 1{,}000}{A \times B \times \text{no. of hours per year.}} = \text{cost per kilowatt-hour of electric energy furnished by primary battery.}$$

If this figure be compared with the cost per kilowatt hour of the current furnished by local electric light companies (which averages about 20 cents per kilowatt hour), even after adding 15 per cent. for loss of current in the storage battery, the result will in most cases show the economy of using stored energy in place of the primary battery. Besides this, it may not be apparent at first sight that in the majority of cases the cost of primary cells is greater than that of a storage battery equipment of like capacity. If to this be added that the space occupied by the storage battery is $\frac{1}{6}$ of that of the primary, another important advantage will be established.

As regards the electrical superiority the electromotive force and internal resistance of the storage battery remain practically constant, while those of the gravity cell are constantly varying as the solution becomes saturated; again, troubles due to corroding connections, creeping salts, etc., met with in the gravity battery, are absent in the case of the storage battery.

These advantages have resulted in the equipment of some of the largest telegraph offices in the country with storage batteries. We have already in these columns given an account of the equipment of the Postal Telegraph Co.'s main office at Baltimore with storage batteries, which have now been in operation for about two years. The plant consists of 480 Chloride storage cells, none of which, we are informed, has required replacing since the original installation.

In order to give you some idea of the manner in which work of this character is carried out, we illustrate in Fig. 1 the plan adopted in the Western Union Telegraph offices at Atlanta, Ga., where 700 Chloride cells are now doing the work formerly done by 8,000 gravity cells. Of the 700 cells 344 are of 72 ampere hour, 172 of 50 ampere hour, and 17 of 25 ampere hour capacity, all used on main lines. Besides this, there are 12 cells of 250 ampere hour capacity, used exclusively for local circuits. The current from the central station is distributed at 500 volts, and in order to reduce it to 110 volts for the main batteries, a $7\frac{1}{2}$ horse power motor dynamo is employed, while the local batteries are charged by a 1 H. P. motor dynamo, which reduces the voltage from 500 to 16 volts. The two sets of main batteries are charged and discharged on alternate days, being divided up into 8 groups of 43 cells each, which are charged in multiple series, and discharged in series. The locals are also charged and discharged on alternate days.

Another very characteristic plant of this nature is that installed at the Central Railroad depot at Jersey City, N. J., the plan of which is illustrated in Fig. 2. In this

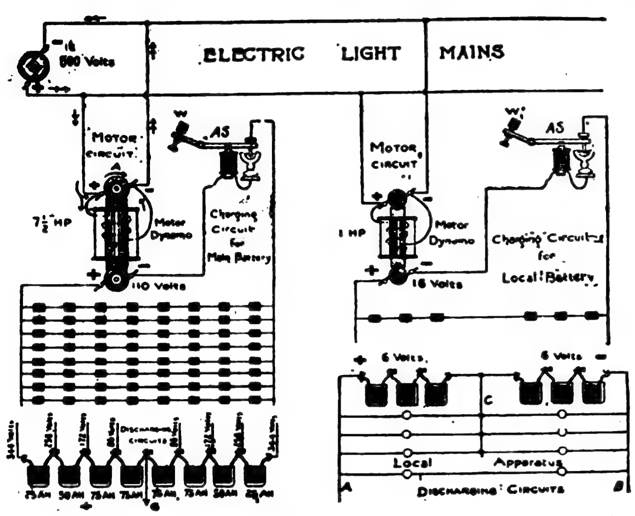


Fig. 1.

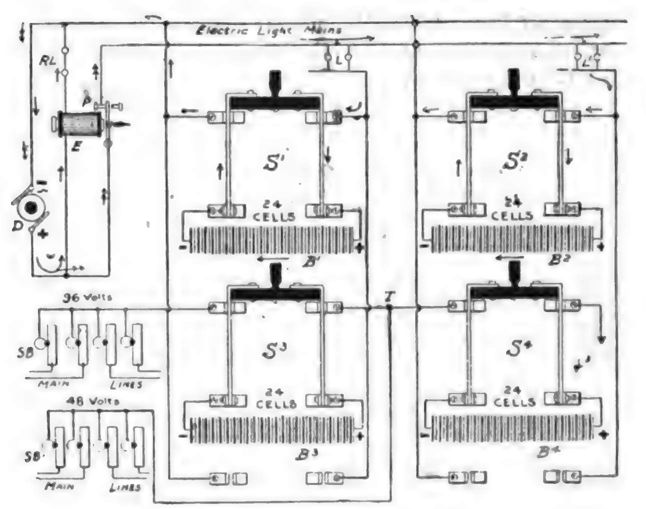

Fig. 2.

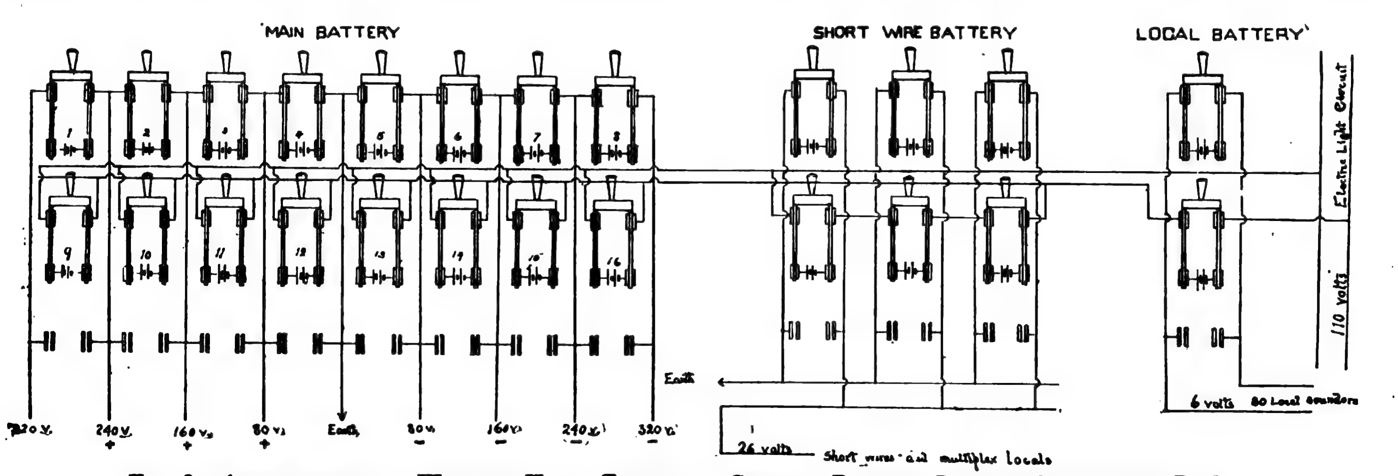

Fig. 3.—Arrangement of Western Union Telegraph Storage Battery Plant, Washington, D. C.

instance the charging is done from 110 volt electric light mains. The potential is reduced to that of the two storage batteries B[1] B[2] by means of the lamps L and L[1]. In this case also there are two sets of batteries and the connections are such that either 48 or 96 volts can be thrown on the main line as occasion requires.

The most important office now in course of equipment is that of the Western Union Telegraph Co. at Washington. Here 724 Chloride cells will be employed consisting of 398 cells of 50 ampere hour, 320 of 12½ ampere hour, and 6 of 125 ampere hour capacity. The arrangement of the installation is shown diagramatically in Fig. 3. As will be seen, the main battery of 640 cells is divided into 16 groups of 40 cells each, shown at No. 1 to 16 in the diagram. The latter also shows batteries 1 to 8 inclusive, discharging in series. Each section of 40 cells is tapped so that four different potentials of each polarity may

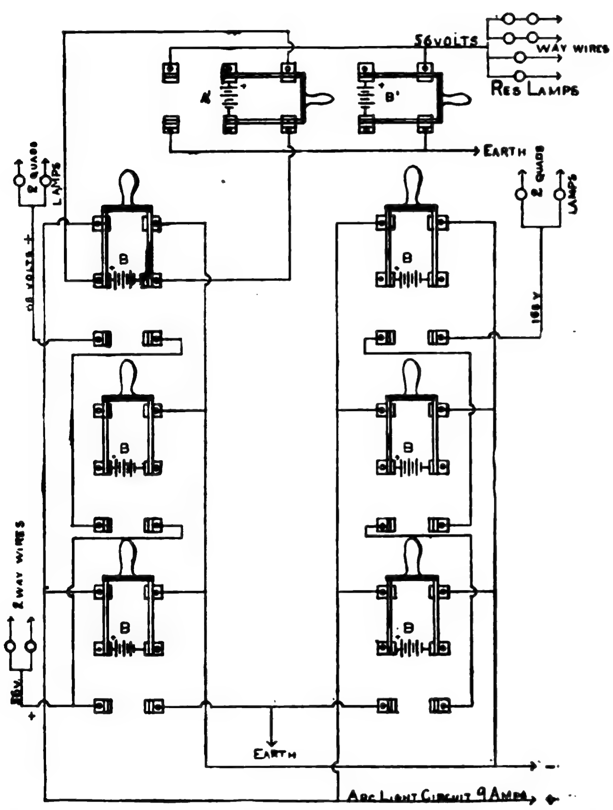

Fig. 4.—Telegraph Storage Battery Arrangement, Long Branch, N. J.

be used for telegraph circuits of various lengths. Batteries 9 to 16 are shown connected in multiple in the charging circuit.

Batteries 1, 2, 7, 8, 9, 10, 15, and 16 are of 12½ ampere hour capacity, while the remainder of the main battery is of 50 ampere hour capacity. The short wire battery consists of 78 cells of 50 ampere hour capacity divided into 6 batteries of 13 cells each, charged in series and discharging in multiple, as shown. The local battery consists of 6 cells of 125 ampere hour capacity. Three of these cells furnish current at 6 volts for 80 local sounders, connected in multiple. The other 3 cells are in the main charging circuit, as shown. It will be observed that both levers of the switches will reach the clips connected with the charging circuit, and that the batteries shown as charging can be discharged, and those shown as discharging, can be charged by throwing over all the levers. In the present instance, the batteries will be changed from charging and discharging every eight hours by means of rheostats. The charging current in each battery will be so regulated that the cells will be replenished in 8 hours. The 724 cells constitute the largest equipment of storage batteries thus far used in any telegraph office in the country, and will replace 7,300 gravity cells heretofore in use.

Another interesting application of a like nature is that recently put in operation at West End, Long Branch, N. J. Here 196 Chloride cells of 6 ampere hour capacity have been installed to take care of the heavy summer business. As shown in the accompanying diagram, Fig. 4, these have been divided into 7 groups of 28 cells each. The batteries are charged in multiple from an arc light circuit every night from 10 to 12 P. M., at the rate of 1½ ampere for each battery. The two batteries, A[1] and B[1], on the double lever switches are charged alternately on succeeding nights, being discharged in series. This arrangement has displaced 450 gravity cells.

Among the telegraph offices not mentioned above, equipped with storage batteries, are those at Allentown, Easton and Scranton, Pa., those at Pittsburg and Hartford, Ct., and Albuquerque, N. M., and various branch offices in New York.

Among the fire alarm systems which have been equipped with storage batteries, may be mentioned that at Philadelphia, where a Chloride accumulator plant operates the police telegraph system, which we illustrate in the accompanying engraving Fig. 5, and which in size

Fig. 5.—Storage Battery on Police Telegraph System, Philadelphia.

presents a strong contrast to the space occupied by the gravity batteries heretofore employed for the same purpose. We may also mention that the fire alarm systems of Hartford, Conn., and Jersey City, N. J., are also equipped with accumulators.

As we have remarked above, it is probably only a question of time when the gravity battery will be relegated to offices of the most minor importance. The work demanded of the storage battery in telegraph work is so uniform that the life of the cell with ordinary treatment ought to be practically indefinite.

ROUNDABOUT NOTES IN ELECTRICAL EUROPE.—II.

BY

E. J. Wessels

FRANKFORT ON THE MAIN.

The only electric road operating in this opulent and beautiful old city is the Frankfort-Offenbacher-Trambahn-Gesellschaft. The road was opened about 11 years ago and has not been extended, owing to the objections on the part of the municipal authorities to overhead wires.

The cars are small and there are few alike. Each seems to differ from its neighbor in some form or other. Contact is made by two sliding shoes which bear against the wire. The wire itself runs underneath a protector closely resembling a gas pipe.

The rail is light and would not stand the pound and rough wear from heavy cars. The road is single track and has numerous turnouts. Siemens-Halske motors are used, one to a car. There is not much power available and cars move slowly. There are no grades, otherwise the cars would often be stalled. The power station is at Oberrad, several miles from the Capital, and is substantially constructed. As in many stations here, much prominence is given to daylight and ventilation. It is very easy to examine all parts of the machinery without artificial light.

The managing director lives over the bureau alongside the powerhouse, and so is in constant touch with everything.

The car wheels are very light and would not answer for American roads. They are chiefly made with spokes. A wheel with a solid face is a rarity. So long as this road is not permitted to reach the heart of Frankfort, its present rolling stock will suffice; but as soon as traffic is heavy, the cars will need to correspond. The road must be regarded as in a transition state and has good possibilities ahead.

The cars are braked with an ordinary hand brake, which answers all purposes since there is an utter absence of speed and grade, and the cars are not overcrowded. Indeed overcrowding is rare The number of seats for passengers is painted on the car, and the number of "standing places." When this number is aboard a placard is hung out announcing that the car is full and thereafter it does'nt stop until some of the passengers alight. This arrangement is excellent for comfort but doesn't improve dividends. This road pays and declares dividends derived from a 10 pfennig fare (2½c.).

Iron and wood poles are used, and these are attractively painted. At places where cars are stopped, attractive porcelain signs appear, which explain that these are halting places.

On this route one cannot find anything which is an improvement upon American practice. Indeed, if some of the methods employed on suburban roads there were practised on the Frankfort road, it is most likely that the riding public would have helped the company to secure further rights and extensions. There is not much to show for an eleven years' existence. Details of generators, motors, etc., are omitted as the system is too small to warrant special mention.

HANOVER.

This most important city is the seat of vast manufacturing enterprises and has a very large population. It is very beautiful, and cleanliness and thoroughness are everywhere apparent. It has the advantage of standing by itself, and its geographical position is unique. It has no large neighboring cities nearer than Braunschweig.

It being progressive, one is not surprised to find that electric traction has here made considerable headway. As in other German cities, the road does not enter the heart of Hanover, so that the riding public is deprived of all-round rapid transit and must patronize the horse cars still in many streets.

All the lines in Hanover (horse and electric) are under one control. The service is cheap and excellent. The cost of construction of the electric road exceeds that in America, as the paving demanded is "gilt-edged." In fact it seems too good, viewed in the light of dividends.

The Hanover electric road has in active service 32 motor cars and 150 trailers. With the horse car routes we need not concern ourselves as the horse is bound to go shortly. The electric road extends from the outskirts of the city, beyond, and the power house is conveniently situated in case the whole system is converted into electric. The motor cars are not standard but are of different types and come from Holland, Belgium, France and Germany. There is great diversity in the trucks also. Few are alike, and the absence of springs is apparent when one takes a long ride. The trucks are rigid and make sorry work when rounding curves.

Apropos of these narrow gauge roads it may be well to state that even if swiveling trucks were used, matters would not be improved, as the roads are so crooked and many of the streets so narrow, that there would not be sufficient clearance for the car bodies.

The electrical equipment was furnished by Siemens & Halske, Berlin. High speed is unusual but there is no reason why this could not be made. The road bed is in excellent condition. The fare is 10 pfennigs, and last year the road paid 3½ per cent. dividends. Clement Adam is chief engineer, and the managing director is Theodore Krüger. The road has only been running since 1893. It has four divisions and is 13 kilometers long (about 8 miles). It is free from grades and on the small motor cars drawing short trailers braking is done by the motorman who applies his hand brake and depends upon his car for the braking of the trailer. This at best is a hazardous performance and bumping is inevitable.

A curious contrivance which exists in Hanover and elsewhere is the bell for warning pedestrians and drivers of the approach of the car. There is no gong worked by the foot, but instead, above the brake handle and attached thereto, is a bell which has a sliding hammer. The motorman raises and lowers this, which makes the bell ring with a sharp clear note. It is preferable to some of our gongs and might be used to advantage.

The controller is of peculiar shape and by no means as compact or convenient as the well known types in America. It is round, lies flat against the dasher and is more clumsy to operate than the American type. I saw a test of accumulators made on this road. There were four parties checking the readings against each other. It was interesting to observe that they discarded the German amperemeter they started out with and used the Weston instruments entirely.

The poles on the Hanover route are graceful and painted attractively. In a number of places the span wires are held by fancy rosettes which are fastened to the masonry of the buildings. All the cars abound in signs "Nicht spucken" (do not spit) "Nicht rauchen" (do not smoke). They have very wide platforms and look much like the "Accelerator" cars at home but for the location of the doors.

One is impressed with the gentlemanly conduct of the conductors. They usually greet you with "good morning" or "good afternoon" and thank you when you have paid your fare. Something of this sort would produce good results on some of our American roads.

SAVE A LOT OF TIME AND LABOR.

Mr. C. Doutre, electrical engineer for the Richelieu Ontario Navigation Co., Montreal, Can., writes: "The Data Sheets you are at present issuing are very good; they save a lot of time and labor."

THE BELFAST GAS ENGINE-STORAGE BATTERY STATION.[1]

The latest development in gas-engine stations for electric supply is represented by the station recently put into operation by the Corporation of Belfast, Ireland. As long ago as February, 1893, the plans for a system of supply to a limited area were laid before the City Council by Prof. A. B. W. Kennedy, and were accepted; these forming the scheme upon which the present works have been carried out. No doubt, on account of the experimental nature of the trial of gas power, as well as from the fact that it is a simpler matter to duplicate such stations than stations driven by steam power, it was decided to restrict the capacity of the station to 8,500 lamps, allowing that only 6,100 lamps will be alight simultaneously in the ordinary course.

System Adopted.—The system which was decided upon by the Corporation, on the recommendation of Prof. Kennedy, was as follows: Power was to be derived from the Corporation town gas mains, the gaseous fuel being used to drive gas engines; these engines were to be geared by ropes to continuous-current dynamos, which, in conjunction with a large storage battery, were to feed a network of 220-volt three-wire mains, consisting partly of bare copper strip and partly of covered cables, by means of feeders of copper strip and covered cable. Balancing dynamos and a suitable system of battery switching were to be employed for keeping the two 110-volt sections of the three-wire system properly regulated. The scheme included no provision for street lighting; but, as has been said, it made ample allowance for the supply of 6,100 glow lamps simultaneously. The estimated cost of the plant for the generation, storage, and distribution of power for this system of supply was £19,000, exclusive of land, buildings, and consumers' meters.

The general arrangements of the engine and battery rooms, and of the outlying offices, &c., may be learned from Fig. 1, by means of the key which accompanies that illustration. In every way these seem well adapted to the peculiarities of the system and to give efficient service. Fig. 2 is from a photograph of the interior of the engine room looking in the direction of the switchboard.

The present equipment of the engine room comprises altogether six sets of rope geared gas-engines and dynamos. Four of these sets are for the general supply through the feeders, and the remaining two—which are of smaller power—may be used either for this same purpose or for balancing the three-wire sections. The smaller dynamos are provided with special commutator arrangements—which will be described presently—to enable them to fulfill this double duty, being in the former case required to give 220 volts, and in the latter instance only half that pressure. Gas is metered into the station through two large meters, and passes along one large supply pipe, from which branch pipes convey the gas to the several engines. The Corporation makes a charge for gas at the rate of 2s. 3d. per 1,000 cubic ft. The charge to townsfolk for gas is 2s. 9d. per 1,000 cubic ft., with discounts.

Gas Engines.—As already has been stated, there are six gas engines now installed. These have been constructed to Prof. Kennedy's specifications by Messrs. Dick, Kerr and Co., of Kilmarnock. Four of these engines are capable of developing a maximum of 120 I. H. P., and are used for driving four Siemens 60-kilowatt dynamos. The remaining two engines are coupled to Siemens 26.5-kilowatt dynamos. The contractors have guaranteed that the consumption of Belfast gas by these engines, when at their rated load, shall not exceed 26 cubic ft. per electrical horse-power per hour, as measured at the dynamo terminals. By a six-hours' trial at the contractors' works, it was found that the consumption of Kilmarnock gas did not exceed 24 cubic ft. per electrical horse-power hour, under the specified conditions. The combined $\frac{\text{E.H.P.}}{\text{I.H.P.}}$ efficiency of the engines proved to be about 76 per cent.

The engines have each two cylinders, both double-acting and are thus capable of giving an impulse at each stroke. The two pistons are arranged on the same rod; there is only one crank, the cylinders are placed in tandem, and the width of the engine is no more than that of a single-cylinder engine of half the power. In order that this arrangement might not spoil by increased length the economy of space which resulted from decreased breadth, the method of backward driving was adopted, the cylinders being located between the flywheel and the dynamo alongside of the rope-drive. Thus the amount of floor space covered by the plant is actually less than would be required by a forward-driving single-cylinder engine of equal power. Again, in order that backward driving should not put the ropes into slack tension at the bottom and tight tension at the top—a plan which would cause the ropes to lift off the pulley grooves except over a small arc, thus making the ropes slip—it became necessary to design the engine so that it would turn the flywheel in the reverse to the usual direction. That this method results in getting a compact engine room, a glance at the engraving (Fig. 2) will suffice to show. A scale drawing of one of the larger of the Belfast engines is shown in Fig. 3.

The cycle of operations which is carried on at each end of both cylinders is the well known Otto cycle. The phase relations of the four cycles are adjusted so that, at full load, there is a quick succession of impulses; no two impulses in any one engine occurring at the same time. The explosions occur in the following order: first, there is an explosion in the back end of the back cylinder, then one in the front end of the front cylinder, then one in the back end of the front cylinder. Thus, by the distribution of the load among four suitably arranged Otto cycles, it is probable that the tendency to fluctuation is reduced to one-sixteenth of the tendency in a single-acting single-cylinder engine of equal horse-power and flywheel inertia.

The engines are designed to run at constant speed—160 revolutions per minute—at all loads, accurate speeding-up being as yet practically impossible in gas engines. At full load there will therefore be 320 impulses per minute. It was originally intended to arrange that at reduced loads the engines would systematically miss one or more of their 4-cycle explosions. This arrangement, however, has not been finally adopted, it being found to be preferable to arrange that the whole of the regulation by the governor shall be effected by varying the proportion of gas used in all four explosions. The four large gas engines are each provided with 8 ft. 5 in. cast-iron grooved pulleys, which drive the large dynamos by means of eight 1-in. ropes on each pulley. In addition to the grooved pulley each crank shaft carries a heavy cast-iron flywheel for giving greater steadiness in running.

One of the problems in connection with a gas-engine station is, how to arrange to economically and quickly start the engines as they are required. The practice of pumping or otherwise admitting an explosive mixture into the motionless and inert engine, and then firing the machinery into activity by one sudden blast is used in some places, but it puts a heavy strain on the parts which are thus suddenly set in rapid motion, and it is not one which an

FIG. 1.—ENGINE AND BATTERY ROOM, BELFAST STATION.—PLAN VIEW.

1. Abstract from the London *Electrician*.

engineer could ever bring himself to admire. At Belfast the simple expedient of running the dynamos as motors off the station batteries, or other engines when any are running, is resorted to, the dynamos thereby running the engines until the proper charge

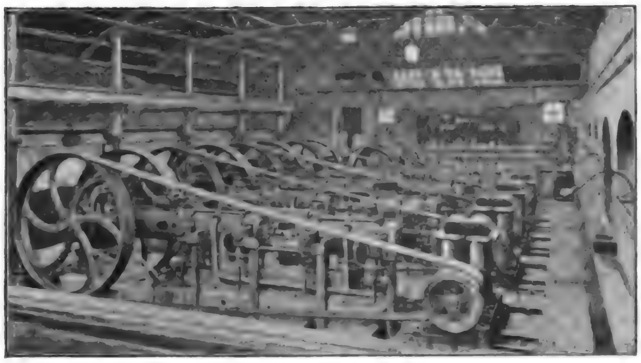

Fig. 2.—Engine and Dynamo Room, Belfast Central Station.

has been drawn into the cylinders and compressed, when it explodes and the engine runs up to the speed controlled by the governor. The amount of current sent through the dynamo when starting-up is regulated by a hand rheostat, the hand gear for which is situated by the switch platform rail, overlooking the engine room, and the resistance frames are placed beneath that platform.

Dynamos.—The six dynamos for this station were supplied by Messrs. Siemens Bros. & Co. The four larger machines are rated at 60 kilowatts, but are normally only intended to develop about 57½ kilowatts. They are two-pole, drum-wound, shunt machines, and are designed to run at 600 revolutions per minute. Under normal working the field is regulated to give from 225 to 240 volts at this speed, but the machines can be made to develop as high as 250 volts for exceptional work.

The two smaller machines call for more detailed consideration, on account of the diversity of the work for which they are designed. These machines are both of the two-pole shunt-wound type, and each is designed to develop about 26½ kilowatts, running at 750 revolutions per minute. The armature of each of these dynamos is double-wound, each of the windings being connected to an independent commutator. Each winding develops from 110 to 120 volts, at normal speed and excitation; and there are switchboard arrangements for putting these two windings in series or in parallel. When they are in series the voltage of the machine is, of course, normally between 220 and 240 volts; but on occasion, with this arrangement, a voltage of 270 volts is developed. These machines, when run with the armature winding of each in

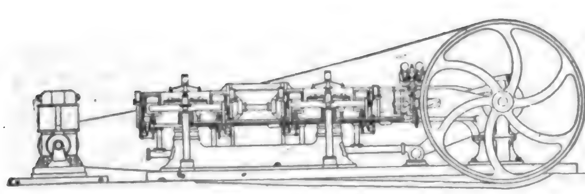

Fig. 3.—Gas Engine and Dynamo.—Side Elevation.

parallel, are intended for use as balancing machines on the three-wire network.

Electric Storage Plant.—At the Belfast station there are two large storage batteries, one for each of the two sections of the three-wire network. The arrangement of these batteries in their special room is shown in Fig. 4, which gives a perspective view of a battery room about 28 ft. square. Each battery consists of 63 E. P. S. cells of the 34-K type, in lead vessels. Besides these, there is a reserve of eight "hospital" cells, or "milkers."

Battery Regulation.—The unique system of battery regulation which is in vogue at the Belfast station, has been designed by Prof. Kennedy and one of his assistants, Mr. B. M. Jenkin. The usual plan of entirely cutting the end cells out of circuit, on the positive or negative battery, when the pressure on one side of the system is to be lowered, has here been abandoned, every cell being retained in the circuit, whatever the pressure required on the feeders. In order to regulate the pressure applied to the feeders, the end cells of the batteries, which are most remote from those connected to the bus bars on the switchboard, are put in parallel with one another—the last few cells of the two batteries being, as it were, electrically telescoped; and the number of cells on each battery thus placed in parallel with the similar cells on the other battery is made to vary with the total pressure required between the positive and negative feeders. In addition, the point of connection of the middle wire will be shifted either towards the positive or towards the negative end—this middle wire making, of course, a contact at some point on the telescoped cells on each of the batteries—according as it is desired to give either side a greater or lesser pressure.

This ingenious method of getting over the need for removing cells from the circuit in order to regulate the pressure is more clearly explained by reference to Figs. 5 and 6. In Fig. 5 it is supposed that the pressure of only 106 cells is required between the positive and negative feeders, and that an equal number of cells is required on the two sections. Now, there are in all 126 cells in the two batteries; so that 20 have to be put in parallel with another 20. In order to do this the cells are coupled as shown in the figure; and in order that there may be the pressure of 53 cells on each section, the middle wire must make contact with the 53rd cell of *each* battery. Now, turning to Fig. 6, we suppose that it has been necessary to alter the balance given by Fig. 5, and that we now require the pressure of 54 cells on the positive section, and only that of 53 cells on the negative section. To obtain this, 19 cells will now be "telescoped"—instead of 20, as before—and the middle-wire contact will be with the 54th cell of the positive battery and with the 53rd cell of the negative battery,

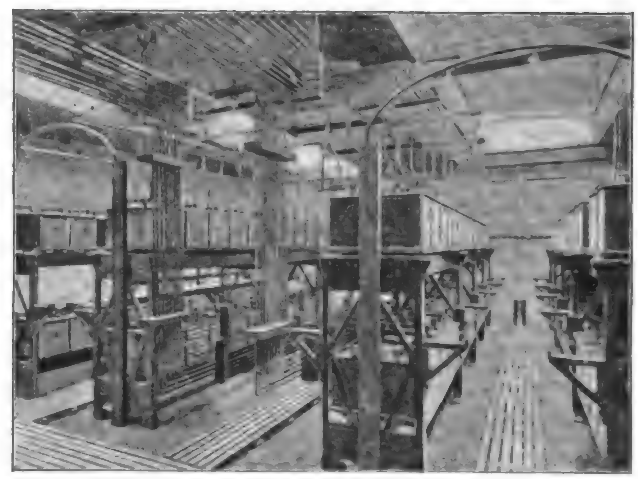

Fig. 4.—The Battery Room, Belfast Central Station.

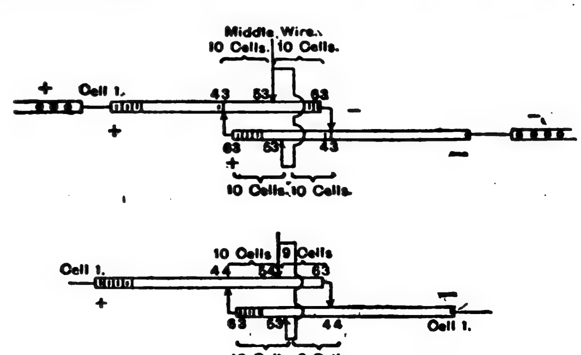
these two cells being at the same potential. In the same way adjustments can be made to give any desired pressure on either section, and it is only necessary to provide that both the middle-wire contacts shall always be with cells at the same potential. This is provided for by a reliable interlocking switch gear, by which it is impossible to short-circuit sections of the batteries or to interrupt the circuits.

This switch is shown diagramatically in Fig. 7. The contacts connected to the cells in each battery on which the regulation is done, are shown lying parallel to each other. Two brushes held by a connecting cross arm connect these contacts to their respective bus bars lying beside them, these bus bars being connected to the end cell (63) of the opposite battery. As this cross arm is moved down it "telescopes" more cells, and if moved up, fewer. By giving one of these brushes a small lead it will make contact



Figs. 5 and 6.

before the other breaks, and in this way the use of pilot brushes is avoided.

The "middle" wire of the system is connected to two bus bars lying outside the contacts by two brushes to these same contacts.

One of the middle wire brushes travels with the centre paralleling switch, while the other remains stationary.

Referring to Figs. 5 and 6, the paralleling switch moves from cell 48 to 44 in each battery, and the middle wire brush on the positive battery moves with it from cell 53 to 54. But the middle wire brush on the negative battery remains stationary on cell 53.

The paralleling brush is worked by a wheel on the front of the switchboard working a pinion geared into a rack.

The whole of the battery can be charged or discharged in parallel with the dynamos, the telescoped cells working at half the rate of the main battery. The telescoped cells can also be charged by themselves by altering the connections at the link switches on the small machines. This arrangement is shown in Fig. 8. Dynamo No. 1, or C, is now between the positive bus bar and the negative *end* of the positive battery; not between the bus bar and the middle-wire contact, as in Fig. 9. Similarly, dynamo No. 2, or D, is between the negative bus bar and the positive *end* of the negative battery. Current is going from the positive of C, by the positive feeders to the mains and lamps, back along the negative feeders to the negative of D, from the positive of D, through the link switch to the positive *end* of the negative battery, where the current splits between the cells in parallel, charging them, then from the negative *end* of the positive battery, through the link switch to the negative of C.

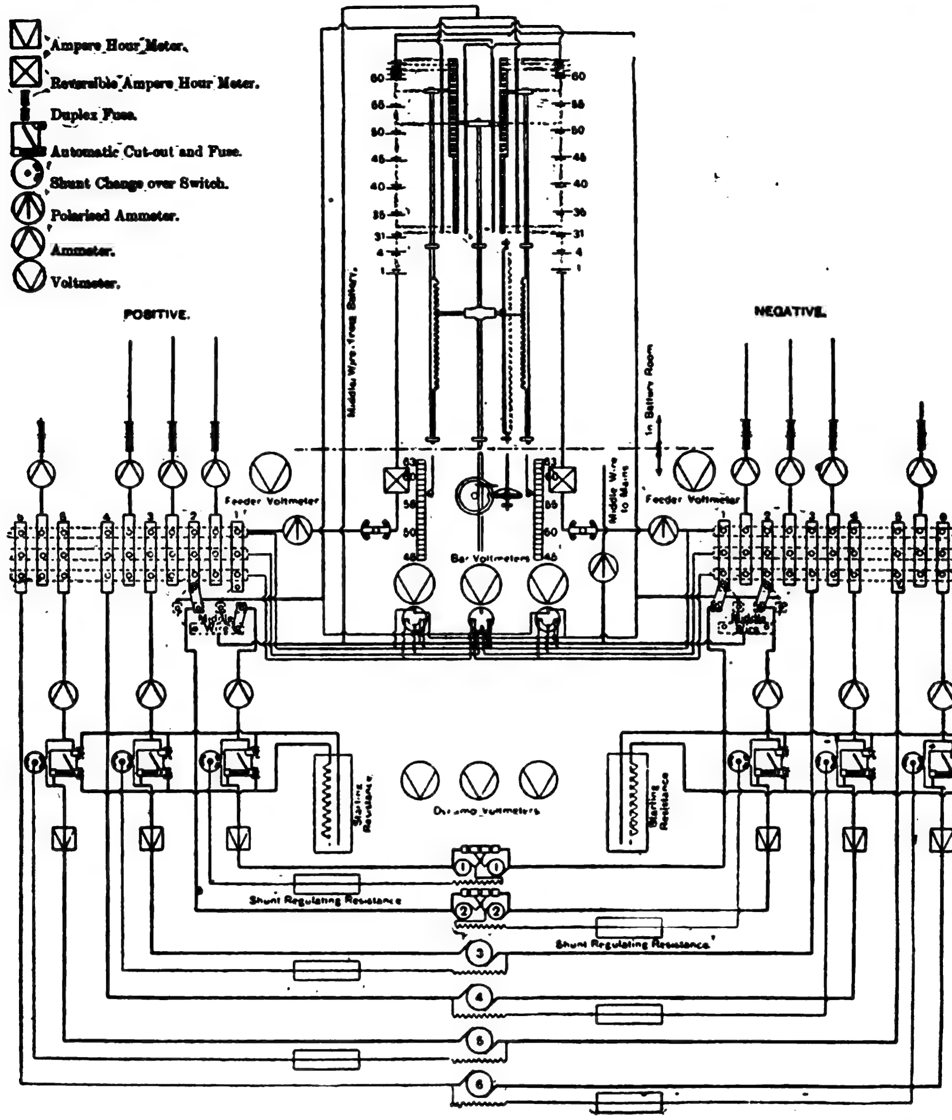


FIG. 7.—DIAGRAM OF SWITCHBOARD CONNECTIONS, BELFAST STATION.

The two balancing machines, C and D, can thus be run at full load on circuit and charge the centre cells at the same time.

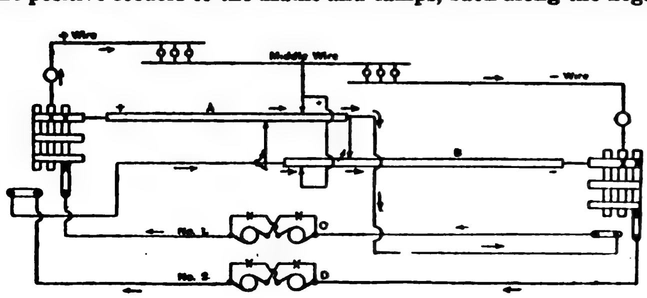

FIG. 8.

As the load on circuit falls the current can be sent into the main part of the battery charging it, and so keeping the dynamos at full load, until the load on circuit has dropped to half that of the small machines, when 100 amperes would be going out on circuit, and 100 into the main battery. As the current on circuit splits equally between the centre cells we have 50 amperes due to it, and also 50 each side due to the 100 amperes charging the main battery; we thus have every cell in the battery charged at 100 amperes.

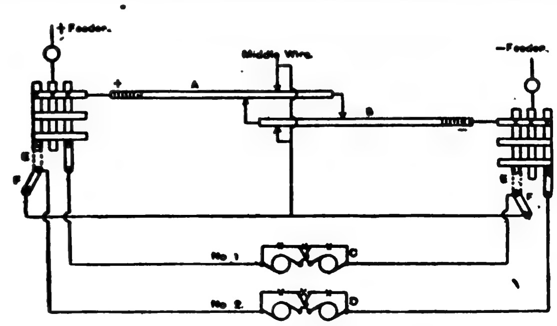

FIG. 9.

This arrangement is only occasionally used when the centre cells want more charge than they get in the ordinary way.

Mains.—The feeding and distributing mains are chiefly of bare

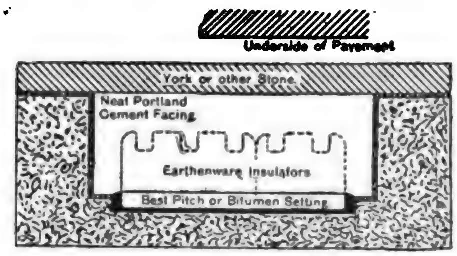

Fig. 10.

copper strip, arranged in concrete conduits and supported on porcelain insulators; but where the mains cross streets, or in some of the narrow streets, or again, in some places where the boggy nature of the soil makes bare copper distribution difficult and risky, covered cables have been laid down. These cables were made by the Callender Bitumen Company. A transverse section of the bare copper strip conduits is shown in Fig. 10. The arrangements of the porcelain insulators for carrying either the three wires, or the three wires and a pair of feeders, will be clearly seen in this drawing. Belfast lies very largely upon a swampy or boggy soil, and this fact has had to be taken account of in the design of the conduits and street boxes, as well as in the arrangement for inspection. There is a small screw plug in each of the street box covers, and each man who goes the round of inspection carries with him a small portable pump and a gauge stick. With the latter instrument, which he inserts into the box after unscrewing the plug, he can gauge the accumulation of water in the box; and with the hand pump he can clear it out.

The whole of the work has been carried out under the superintendence of Prof. Kennedy and his chief assistant, Mr. Burstall; Mr. Victor A. H. McCowan, who was appointed electrical engineer to the Corporation in April, 1894, acting as resident engineer.

ELECTRIC TRANSPORTATION DEPARTMENT.

OPENING OF THE BURLINGTON & MT. HOLLY ELECTRIC BRANCH OF THE PENNSYLVANIA R.R.

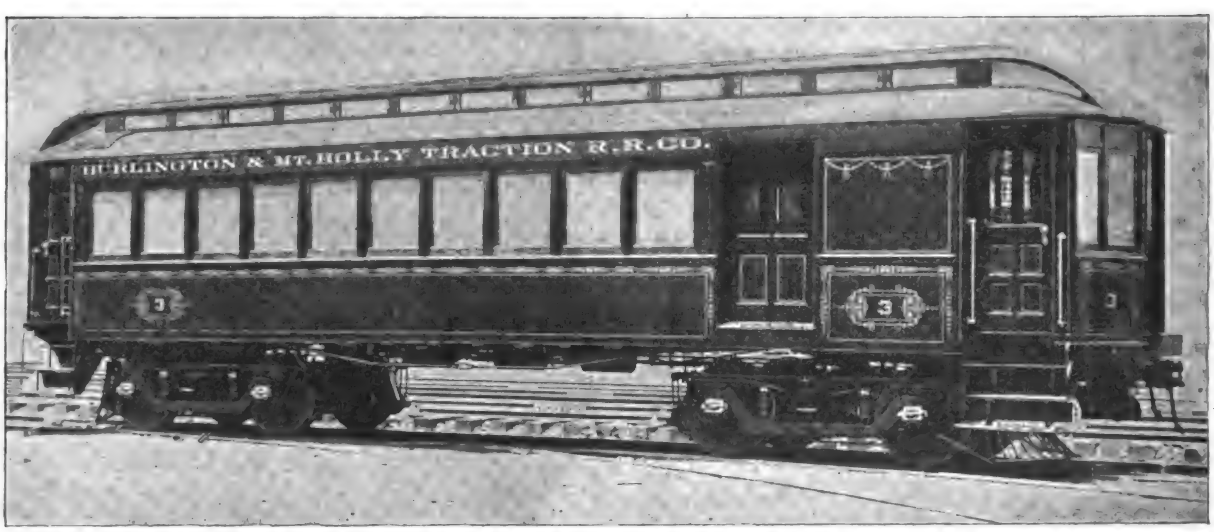
On Monday July 22 the Burlington & Mt. Holly (N. J.) Branch of the Pennsylvania R.R. went into regular operation as an electric railway. The distance between these two towns is 8 miles. The fare is 10 cents each way and 10 trains are run each way on week days and 9 on Sundays.

Span wire construction is used throughout. The poles are of chestnut and are all planted 6 ft. 6 in. below the top of the lowest surrounding ground. The top of every pole is exactly 25 ft. from the top of the rail and on the poles which are used to carry feeders, the cross arms are placed 24 ft. from top of rail. The trolley wire is 22 ft. above the level of the rail.

The feeders are two in number, being each 500,000 c. m. One runs the full length of the road and the other three-fourths of the way. These cables were strung by a construction train composed of a flat car, a pile driver and the locomotive. The span

The motor cars are slightly smaller than the standard Pennsylvania Railroad coach, and have the following dimensions: length of body in frame, thirty-five feet; length over platform, forty-three feet six inches; width of car at sills, nine feet four inches. The cars were built by the Jackson & Sharp Company and have closed vestibule ends with side doors. The interior finish is of Mexican mahogany, light in color, and the side and top ceilings are of handsomely figured white birch veneer, highly polished, but without a line of decoration.

As it is the purpose of the railroad company to haul regular passenger coaches as trailers, the motor cars are equipped with the company's standard Jenney platforms, couplers and buffers and have an end entrance for passage from one car to the other. The seats are of the Bushnell type, with reversible fixtures and tilting cushions. They are upholstered in crimson plush, but are not fitted with the usual side arm. This is quite a novel feature, and one which it is thought will prove attractive to the traveling public, as it affords more comfort and gives more room.



Combination Passenger and Baggage Motor Car, Mt. Holly & Burlington R. R.

wire for supporting the trolley, is ⅜-inch galvanized standard cable, fastened to ⅝-inch drop forged eye bolts. The trolley wire is No. 00 hard drawn copper and was stretched by another construction train composed of a tower car and engine. The track is the same as the steam road with the exception that the joints are bonded on the outside of the rail and a supplementary wire is run along on each side, there being two supplementary wires.

The power plant is located at the Mount Holly terminus and consists of a Westinghouse direct coupled generator and compound engine, and a Climax boiler of 300 H. P. capacity. There are three motor cars of sufficient power to draw standard Pennsylvania Railroad coaches for trailers and maintain a speed of from forty-five to sixty miles an hour.

The lighting is by electricity with lamps along each side of the roof. There are also auxiliary fixtures in the center for burning oil if the current should give out. The cars will be equipped with twenty-two Central Electric heaters, one under each seat in the passenger compartment and two in the baggage compartment.

The trucks are of the Jackson & Sharp Company's standard type, made to conform to the Pennsylvania Railroad standard requirements as to pedestals, boxes, journal brasses, etc. The wheels are thirty-six inches in diameter, and a part of them were furnished by the Allen Paper Wheel Company, and a part by the Standard Car Wheel Company. The axles, motor supports and other parts are designed to carry Westinghouse seventy-five H. P. motors, two to each car, although the

first car was equipped with four fifty H. P. motors. Attached to the front part of each truck there is a light iron fender, made on the same principle as the ordinary locomotive cow-catcher. This is only intended as a protection for safety and to prevent a derailment of the train, and is intended to remove all obstacles from the track.

The baggage compartment in these cars is finished in the usual manner, so that baggage, express and marketing can be conveniently handled. There are also in this compartment, however, side seats with a hinged section to cover the space of the side doors. These seats are designed for the use of smokers, so that the car may practically be termed a combination smoking, baggage and passenger car.

The cars are equipped with Westinghouse air-brakes supplied with air pressure by a special compressor operated by a small electric motor. This motor is arranged to be cut out of service when the normal pressure has been reached in the reservoirs.

THE BOILER HOUSE OF THE BALTIMORE TUNNEL PLANT OF THE BALTIMORE & OHIO R. R.

In our issue of July 10, we gave an illustrated description of the main features of the electric locomotives and power plant of the Baltimore & Ohio R. R. tunnel at Baltimore, a piece of engineering that is deservedly attracting attention from engineers and railway men the world over.

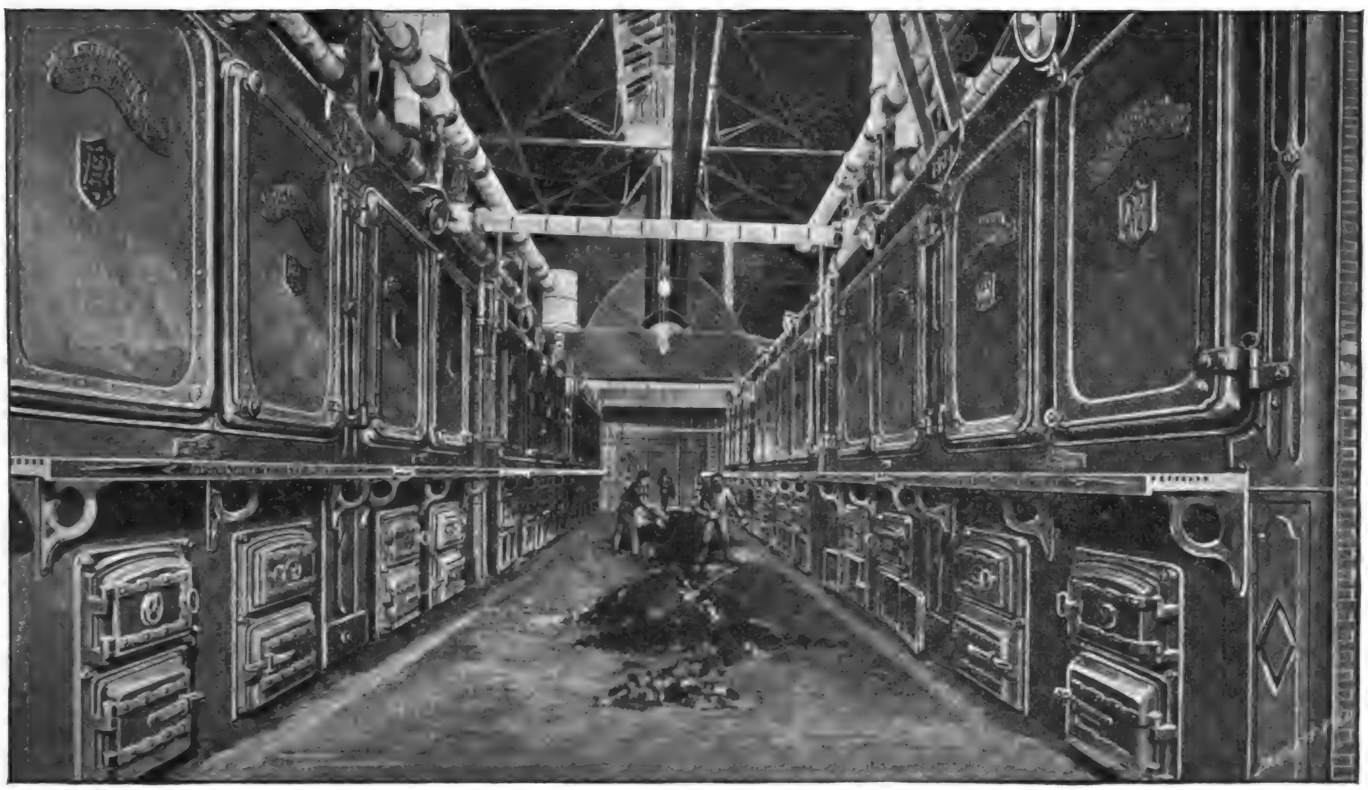
The comprehensive nature of that article made it impossible to dwell in detail on some of the most interesting features of the power plant, among these being the boiler house, but we are now enabled to give a more complete account of this important part of the equipment, which is illustrated in the accompanying engraving. Standing in the foreground the visitor finds himself looking down a fire room some seventeen feet in width and about ninety-four feet in length. On either side improved Root water tube boilers are placed, there being eleven in all, having a total rating of 2,750 horse power. These boilers are arranged in batteries of two boilers each, the odd boiler standing as a half battery. Between each battery a space of thirty inches is found which allows of inspection and cleaning of the exterior of the tubes through the cleaning doors which are placed in the side walls of the boiler. At the further end of the room a space of 21 feet is left between the boilers and end wall, and in this space are found the pumps and heaters of the plant.

On account of the limited space available, it was found impossible to provide a space of over 28 inches between the rear boiler walls and the side walls of the building in which to place the flues connecting the boilers to the chimney, so the main flue was run along the top of the boilers, at their rear, and was made to overlap the 28 inch space. By this arrangement the individual flues from each boiler, after leaving the flue opening in the rear boiler wall, rise to the bottom of the main flue where they enter.

The main flue is made of wrought iron, is rectangular in shape and tapering. At the smallest end it is two feet wide by four feet high, and at its larger end it is six feet wide by seven feet high. It will be understood that there is one main flue of the above description running along at the rear of each row of boilers, one at the right and one at the left. These two main flues finally meet at the further end of the room and join into one common smoke box, also rectangular and made of wrought iron.

The smoke box is clearly shown in the cut, and behind it can be seen the outlets of two pressure fans, which are continually exhausting the gases, etc., from the large smoke box, and they finally discharge these gases into the vertical stack which is plainly seen in the centre, rising through the roof. Thus the gases are handled by what is termed an "induced draught."

The steam piping commands the attention of the engineer the moment he steps into the boiler room. Its graceful and easy curves allow for all expansion and contraction which may take place along the line of pipes. A system of duplicate steam mains with the proper connections makes it possible to throw out of service, in a very short interval, either one of the two steam mains and to change the work entirely to the other; and it is also possible to cut out or throw in any one, or any number of the boilers without interfering with the continuous operation of the plant.



Battery of Root Boilers in The Baltimore Tunnel Electric Power House.

The steam mains run through the boiler room over the top of the boilers, collecting their supply of steam from each boiler as they pass it. At the further end of the room, these steam mains drop below the level of the floor, into a large trench, along which they run to the opposite end of the engine room with risers running up to each engine they pass.

Many do not understand that this is a central lighting plant as well as a central power station, supplying the necessary current to take the trains over the Belt Line through the tunnel and besides this service three of the boilers are designed to take care of the lighting of the many incandescent lights to be placed throughout the tunnel, and also to further furnish current for the numerous arc lights distributed through the local yards of the Baltimore and Ohio Railroad Co.

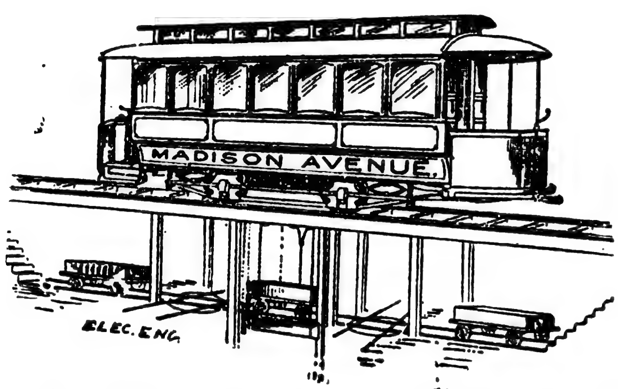
As this was the first railroad to adopt electric locomotives, the greatest care was exercised by the General Electric Co. to make it, in every way, a success, and nothing was contracted for that had not been thoroughly tested by them and found equal to every demand that could be made upon it in this plant. With a view to the selection of the boilers, the Root boilers in their Lynn Thomson-Houston factory plant were subjected to

very severe tests and were found equal to every demand made upon them. These tests led to their adoption for the Baltimore & Ohio Railroad and also for the new plant they afterwards erected in Lynn known as the "River Plant."

STORAGE BATTERY CARS ON MADISON AVE., NEW YORK.

It is now nearly six years that an attempt was made to operate the Madison Ave. street cars in New York by means of storage battery traction, and although ten cars were equipped in all, the results attained did not appear to warrant the adoption of the system. Since that time considerable progress has been made in storage battery traction and the continued successful operation of three lines in Paris equipped with storage cars, in one case extending over two years, has demonstrated that this mode of traction is now commercially practicable. Much of the success attained in Paris is no doubt due to the improved type of cell employed, the Chloride accumulator being used on all the lines, and the cars on the Madison Ave. line will also be equipped with this type of cell, manufactured by the Electric Storage Battery Co.

These cars, which are now in course of construction, will be of the standard type of electric car, 18-foot body and about 23 feet over all. They will be mounted on Peckham trucks, carrying General Electric motors. The cars will have many improvements over the old type of electric car. For example, the batteries will not be carried in the car body, as has been hitherto the practice, but will be suspended from the truck under the centre of the car, as shown in the accompanying engraving. The tray or box containing the batteries is readily and quickly detachable from the truck and removed, for the purpose of charging, on a



Charging Arrangement for Storage Cars, Madison Avenue Line, New York.

small transfer car running on rails to and from an elevator situated between the street car tracks and running beneath the floor to a cellar or subway, the elevator being adapted to hoist the batteries into place on the car truck, or to remove them therefrom, as the case may be. By this novel arrangement a car can be loaded and unloaded in about half a minute. It will be seen that with this new system of carrying the batteries on the truck any car body is adapted for use in this service, thereby saving a company adopting the system considerable expense by enabling it to use its present car bodies.

ELECTRICITY ON THE ERIE CANAL.

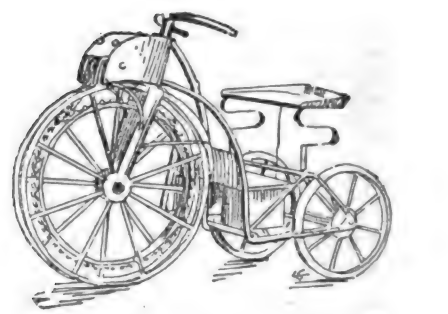
Mr. Frank W. Hawley, representing the Cataract General Electric Company, has applied to the New York State Superintendent of Public Works for permission to experiment with a new system for towing boats on the canals by electricity. The test will be made Sept. 25, on the Erie Canal, for a distance of four miles between Buffalo and Tonawanda. The Cooper & Hewitt cable traction system will be used and operated from the canal bank. The electricity will be furnished by the Niagara Power Company. The experiment will be made on a four-mile section of the canal upon which are overhead bridges and sharp curves, in order that the system may be fully tested.

SUTRO POWER HOUSE, SAN FRANCISCO.

The Sutro Electric Railroad is rapidly nearing completion, and by the middle of October at the latest, and probably sooner, the line may be expected to be in operation. The plans for the power house, which will adjoin the baths, will include a promenade on the roof, which will be of iron and glass. From the roof a view of the ocean can be obtained, and the machinery in motion also can be seen. The building will be one story in height. Contracts for the engines, dynamos and generators have been let to the Fulton Iron Works of San Francisco.

THE BARROWS ELECTRIC TRICYCLE.

The accompanying engraving represents a model of an electric tricycle design, by Mr. Charles H. Barrows of Willimantic, Conn. The forward wheel is the driver and is constructed with two rubber-tired rims, between which is what corresponds with the sprocket in the bicycle. The electric motor is carried in a box



The Barrows Electric Tricycle.

over the driver and is connected with the driver by a sprocket chain. The storage battery is placed between the two rear wheels.

A seat capable of carrying from one to three persons is over the smaller rubber or pneumatic tire wheels. The guiding device is similar to that of the ordinary bicycle.

PROPORTION OF DEATHS BY TROLLEY ACCIDENT.

When it comes to a comparison of our trolley traffic, says the *Brooklyn Eagle*, with the death rate on the great steam roads, the proportion is astonishingly in favor of the much denounced Brooklyn trolleys. This is the more notable as the steam roads have their tracks guarded from the intrusion of pedestrians to a great extent. They have raised crossings at the more dangerous points along their lines and the precautions for the protection of life by the block signal system and otherwise are elaborate and ingenious. Yet the New York Central railroad reports one death for every 69,000 passengers which it carried; the Delaware, Lackawanna and Western one death to every 67,000 passengers; the New York, Lake Erie and Western one death to every 110,000 passengers. If the Brooklyn trolleys or any other trolleys made a death rate like that, there would be riot in the city until the cars were removed from the streets. (In Brooklyn the proportion is only 1 in every 8,135,000 persons carried.—Eds. E. E.) No one hears anything about the Central juggernaut or the Erie juggernaut. This is not a plea for reckless trolley running, nor for an increase in the Brooklyn death rate by means of accidents, but there is good traditional authority for giving the prince of darkness his due, and when the railroad officials are able to show that their death rate is lower than that in other cities and far lower than that of steam roads running through large thinly settled districts the facts ought to be considered before unlimited denunciation is dealt out to them. The trolleys were placed on our streets by the consent of the city. Even their most virulent critics do not want to return to the horse cars. When the officers of the lines are making vigilant efforts to reduce the number of accidents they are entitled to fair play in public discussion.

GOOD BRAKES NEEDED FOR STREET CARS.

Referring to our advocacy of air brakes for street cars the Syracuse *Courier* remarks: An electrical paper, in discussing the question of fenders as life preservers for electric cars, suggests that good brakes are more of a necessity to street cars than the fenders, concerning which so much is being said about the country. Very likely this conclusion is correct. Inventors are reported to have already devised power brakes by which the motorman, by a slight movement of the hand, can almost instantaneously stop a car, while running even at a very high rate of speed. These brakes are quite expensive and for this reason, possibly, they have not been, as a rule, adopted by the trolley companies. The time will come, however, when the railroad companies will be compelled, both by public opinion and by business considerations, to adopt every or any practical appliance, no matter how expensive it may be, which will protect human life. Costly litigation will follow the killing of people on the public streets, and in time, if the killing continues, the damages that in many instances must necessarily be paid will far exceed the cost of appliances which would prevent such accidents. The objection is raised by the trolley companies to the use of the instantaneous brake, that the immediate stopping of the car would shake up the passengers and possibly bruise some of them. This argument is not a tenable one, for steam

cars running at the rate of forty or fifty miles an hour, are often stopped by the application of air brakes and the reversing of the engine to prevent accidents, even if the passengers are somewhat shaken up by the operation. It would be better for the trolleys to slightly bruise a few people than to kill one by their inability to stop in time to prevent such killing. In the long run the most expensive appliances for the trolley cars may become the cheapest.

THE USE OF ELECTRIC POWER BY THE CHICAGO & NORTHERN PACIFIC AND THE "C. B. & Q."

Suburban residents along the lines of the Chicago and Northern Pacific and the Chicago, Burlington and Quincy railroads will soon be able to ride to and from the city on swift-running electric trains. The Northern Pacific is about to substitute electricity for steam on its line, as already announced and a new corporation is planning an extensive system of trolley lines along the Burlington to reach the towns of La Grange, Grossdale, Austin, Ridgeland, Oak Park and Lyons. The Town Board of Cicero has granted franchises for both enterprises, and their backers assert they will be pushed to an early completion.

The improvement proposed by the Northern Pacific contemplates the use of electric power instead of steam over its entire system, and is regarded by railroad men as one of the most important departures for years. This road will, in fact, be the first in the West to use electricity for its motive power. It is expected that the steam locomotives will be abandoned within four months. General Manager Samuel P. Ainslie says: "I do not wish to discuss the matter just now. I will say, however, that it is true we were granted an ordinance by the township of Cicero to operate our trains under a new system. We expect to equip our entire service with the new power."

The franchise granted by the trustees of Cicero, at an adjourned meeting, permits the Northern Pacific to run its trains through that town by electric power, which indicates the change which Mr. Ainslie admits is to be made. More than that, the Northern Pacific has already the basis for a mammoth electric power plant in its station at Harrison street and Fifth avenue. When that structure was erected it was planned with a view to ultimately using electricity for motive power in the place of steam. Not only were the foundations put in for a possible power house in the future, but many other features were embodied in its construction to make the conversion of a part of it into a power house a matter of few and quick changes. The plan to replace steam locomotives with electric power can, therefore, be thus carried out with a great saving of time and expense.

The trolley system along the Burlington line is to be constructed by a new corporation, known as the Suburban Electric Company. It has already filed a bond of $20,000 as a guarantee that it would carry out the project on which it secured the right of way from the town of Cicero.

The franchise requires that the new system shall be completed within two years and put in operation, the penalty being a forfeiture of the grant. Its backers declare they have already secured the assent of a majority of the property owners along the right of way. They are confident there will be no opposition, and anticipate no serious difficulty in carrying the project to completion within the specified time.

HEATING CARS BY ELECTRICITY IN MASSACHUSETTS.

The Massachusetts railroad commissioners have sent out the following interesting and important decision in the matter of the heating of street railway cars:

Under the provisions of chapter 136 of the acts of 1895, entitled "An act relative to the heating of street railway cars," after notice to the several street railway companies and a public hearing of such as desired to be heard, and upon consideration by the board, it is determined and

Ordered, That the following requirements and regulations be prescribed and notified to the several companies relative to the subject matter of the aforesaid act:

Regulations for the heating of street railway cars:

1. The several street railway companies shall equip such electric box cars as are used by them for the transportation of passengers in the months of November, December, January, February or March in each year with suitable apparatus for heating the same by electricity; provided, that other than electric heaters may continue to be used in such cars as are now equipped therewith, until the further order of the board.

2. Electric box cars, while in use for the purpose and during the months aforesaid, shall, whenever the outside temperature is less than 50° above zero (Fahrenheit), be kept warmed by such electric or other heaters to an inside temperature (as near as may be) of not less than 50° nor more than 60° above zero, except at times when the company is temporarily prevented from so doing by storms, accident or other controlling emergency.

3. These regulations shall take effect on the 1st day of November, 1895, and may be modified from time to time in general or in particular as experience and the public comfort may seem to the board to require.

WESTINGHOUSE COMPANY AND BALDWIN LOCOMOTIVE WORKS COMBINE FORCES.

On Aug. 5 the important announcement was made that a working arrangement had been effected between the Westinghouse Company and the Baldwin Locomotive Works of Philadelphia. The arrangement is not of the nature of a combination of capital, but solely one of interests.

Commenting on the new departure in an interview a member of the firm of Burnham, Williams & Co., proprietors of the Baldwin Locomotive Works, said: "We have long been thinking that the Baldwin Locomotive Works should take a prominent position in the manufacture of electrical engines, but we found the electrical field so well covered by patents that an outsider must work under great disadvantage. The negotiations between the two companies to overcome this difficulty have been going on for more than two months, and we are now ready to join and undertake any contracts for locomotives run by electrical power."

No immediate extension of the Baldwin plant is contemplated as a result of the deal. The Baldwin works have already experimented in the construction of electrical engines. One was built recently for Henry Villard of the North American Company, to the designs of Messrs. Sprague, Duncan and Hutchinson, and a number of small trucks have been built for elevated railroad use.

It is announced that Mr. David Leonard Barnes, of Chicago, will act as joint superintendent of the companies to overlook the construction of the locomotives. The Baldwin Locomotive Works will confine itself to the building of the rolling stock while the Westinghouse Co. will furnish all the electrical equipment.

CHANGE IN COURSE OF THE CHICAGO HORSELESS VEHICLE RACE.

The course of the horseless vehicle race which will take place on Saturday, November 2, 1895, has been changed, and instead of starting in Milwaukee and terminating in Chicago as at first arranged it will start and end in the latter city. The starting place will be from a point in the southern suburbs which has not as yet been decided upon, and the course will be from Chicago to Waukeegan and back, the length of the run being 100 miles, of which 75 miles will be over perfect roads. On the outward part of the race, it is intended to keep a little inland until Waukeegan is reached, and on the return the road near the lake will be taken and the contestants will pass through Highland Park and Evanston.

It was considered advisable to change the course originally decided upon as a great many Chicago people who would like to see the start and finish of the race would not be able to do so if it were to start from Milwaukee. As the race takes place at a season of the year that is usually very wet, it was thought the roads at the Milwaukee end would possibly be in such condition as to prevent the carriages having a fair trial.

TROLLEY INVADING PENNSYLVANIA MAIN LINE TERRITORY.

The busy trolley has invaded another suburban field hitherto dependent entirely on steam railroad transportation. The extension of the Hestonville system to Overbrook, a suburb of Philadelphia, has been put in operation, and that suburb will henceforth enjoy the advantages of trolley connections with the centre of the city. Cars will be run on a five-minute headway, and a five cent fare will be good for a ride over the entire length of the line. The cars follow the present route of the Hestonville system until Fifty-second street is reached, where they branch off on Lansdowne avenue. Double tracks have been laid on this thoroughfare, and the roadbed is being substantially macadamized. Since the opening of the Haddington line, a short time ago, a remarkable impetus has been given to building operations on Lansdowne avenue. Rows of handsome houses are in course of erection, and many more have been contracted for. Permits were lately issued for the erection of 1200 new houses facing the avenue, bringing the total number projected since the advent of the trolley in Haddington to over 2,000.

Another branch of the Hestonville system will eventually be extended out to Overbrook, by way of Lancaster avenue from Fifty-second street. It is now in process of construction as far as Fifty-sixth street, with double tracks.

TROLLEY RIGHT OF WAY IN NEW YORK STATE.

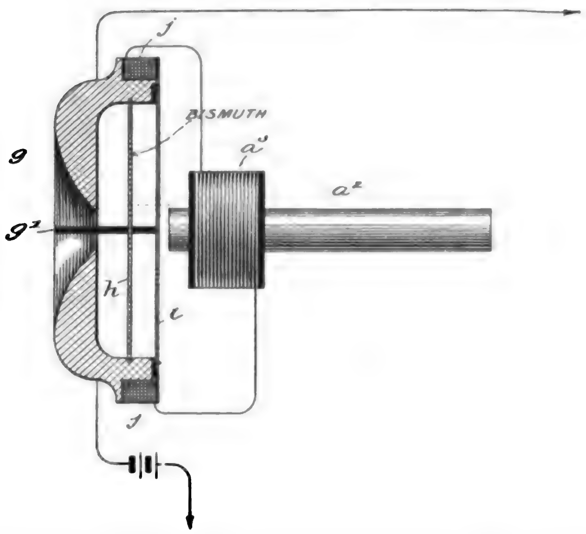
Electric railway companies in New York State will not be slow to take advantage of the law, which has recently become such by the signature of the Governor, which gives to electric railway companies the same rights under condemnation proceedings as are enjoyed by steam railroad companies.

TELEPHONY.

BIGGAR'S BISMUTH MAGNETO TELEPHONE TRANSMITTER.

It is well known that the electrical resistance of bismuth varies when this metal is subjected to the influence of a magnetic field, and the extent of the variation is, within limits, proportional to the strength of the field. This principle is employed in an instrument designed to determine the strength of magnetic fields, by measuring the resistance of a bismuth wire inserted therein.

The same idea has been embodied, though for a different purpose, in a telephone transmitter due to Mr. J. S. Biggar, of San Francisco, Cal. The instrument which is illustrated in the accompanying engraving has a mouth-piece *g* divided into two parts, separated by insulating material g^1. There are two diaphragms, one *h* of bismuth and the other *i* of soft iron and of the usual construction, the latter insulated from the mouth piece. Between the two diaphragms is an air-chamber which conducts the vibrations of one diaphragm to the other. Back of the iron diaphragm is placed the usual permanent magnet and coil. A coil of wire *j* is wound upon the mouthpiece of the instrument



BIGGAR'S BISMUTH MAGNETO TELEPHONE TRANSMITTER.

and surrounds the bismuth diaphragm. This coil is in a closed circuit with the coil upon the permanent magnet. The two parts of the mouthpiece form the terminals of the main circuit, and they are bridged, as shown, by the bismuth diaphragm. It will be seen that the bismuth diaphragm is located in the magnetic circuit of the coil *j*, and that it is therefore subjected to the variations in magnetic force, which cause it to vary the flow of current in the main circuit.

ORGANIZATION OF THE EASTERN TELEPHONE PROTECTIVE ASSOCIATION.

At a meeting held in the Astor House, New York, representatives of various telephone manufacturing firms decided to form an association to be known as the Eastern Telephone Protective Association, and a committee is now preparing suitable by-laws and a complete plan of organization.

The immediate and most important object will be to protect the users of telephones manufactured by others than the Bell Telephone Company.

Among the manufacturers present at the meeting were A. F. Stanley, of Stanley & Patterson, New York; J. D. Leatherbee, of the National Telephone Manufacturing Company, of Boston; J. H. Scofield, of the Phoenix Interior Telephone Company, New York; George W. Coy, of the Franklin Telephone and Electric Company, of New York; H. C. Williamson, of the United Electric Telephone Company, of New York; A. H. Chadbourne, of the United States Telephone Construction Company, of Philadelphia; S. J. Tunbridge, of the Utica Fire Alarm Company, of Utica, N. Y.; James R. Strong, of the Tucker Electrical Construction Company, of this city; H. H. Douglas, of the Century Telephone Company, of Boston; Mr. Palmer, of Palmer Brothers, of Mianus, Conn.; and Mr. Wetmore of the Manhattan Electrical Supply Company of this city.

The next meeting of the Association will be held in New York on Aug. 15 at the Astor House, when the organization will be completed. The Association will be incorporated and the expenses will be borne by pro-rata assessments, and the Association will undertake to defend every individual member against suits for infringement.

CHEAPNESS OF TELEPHONE SERVICE.

Alonzo Burt, general manager of the Missouri and Kansas Telephone company, of Kansas City, Mo., has a novel plan of satisfying people who think they are paying too much for their telephones. During the day the operators keep a record of the complaining subscriber and at night know exactly how many times it has been used. A statement is made up showing the number of calls made and the number answered during the day, or the average for several days. The cost of the telephone for a year is then divided by the number of days to get the cost to the subscriber per day. A telephone that costs $72 a year costs about 20 cents a day. If the telephone has been used twenty times a day, each call has cost the subscriber just one cent or the price of a postal card. The average telephone, however, makes between twelve and thirteen calls a day and answers an equal number, which makes the cost to each subscriber whose telephone is used a little less than one cent for each conversation. The number of calls on a telephone varies. In some houses each interview costs two cents or more, while there are others that do not pay over two or three mills for each interview.

"These statements," says Mr. Burt, "show that it is cheaper to use a telephone than postal cards for any kind of business and of course it is infinitely more satisfactory."

RECENT INSTALLATIONS OF THE WESTERN TELEPHONE CONSTRUCTION CO.

The Western Telephone Construction Co., report the following new installations to be equipped by them:—

The Ticonderoga Telephone Company, Ticonderoga, N. Y., have contracted for apparatus to equip a telephone exchange for that city. They have also arranged for toll lines connecting towns along Lake George and Lake Champlain. The Elgin City Railway Company, Elgin, Ill., have closed a contract to furnish apparatus for a private telephone system. The Altoona Phoenix Telephone Co. will install complete apparatus for a telephone exchange at that point. Wapokonetka, Ohio, will have a new telephone exchange within a short time. The Wapokonetka Telephone Co. have already contracted for the apparatus. The Lansing Telephone Exchange Co. of Lansing, Mich., have contracted for 400 telephone capacity exchange, complete. Barnesville, Ohio, has fallen in line with Newark, Mt. Vernon and Chillicothe, and has contracted for complete apparatus for telephone exchange.

MIANUS ELECTRIC CO.'S NEW GRANULAR CARBON DESK TELEPHONE.

The Mianus Electric Co., of Mianus, Conn., have just brought out a new desk telephone set. This instrument is fitted with their No. 8 granular carbon transmitter that has met with such general approval for short and long distance work. The accompanying illustration shows the set which has an induction coil but is not

MIANUS GRANULAR CARBON DESK TELEPHONE.

wired otherwise, it can, however, be wired for a warehouse or any other system, where more than one cell is necessary.

The Mianus Company sell a large number of these instruments thus equipped to telephone manufacturers who wire them to suit their requirements. They are also made with push button, buzzer and receiver complete. The company also make Blake and carbon ball transmitters and the "silver chime" magneto bells.

TELEPHONE NOTES.

GALLATIN, MO.—The telephone line has been completed.

FAIRFIELD, VA.—The telephone line between Fairfield and Brownsburg is nearing completion.

SOUTH HAVEN, MICH., is to have a telephone exchange with sixty instruments.

SHELBY, MO.—The Shelby County Telephone Company will operate lines to Maud, Holliday, Granville, Paris and Hawkins.

TRENTON, MO.—The telephone line between Trenton and Laredo has been completed.

DILLSBURG, PA.—Bentz & Bailey have contracted for a number of short and long-distance telephone lines.

SELIGMAN, MO., is now connected with the outside world by telephone.

MANKATO, MINN., has granted a franchise for a competing telephone line.

NEW CASTLE, IND.—C. M. Harriman has sold the American Telephone Exchange at New Castle for $4,000 to J. W. Thompson and J. M. Maxom.

SHELBINA, MO.—Shelby County Telephone Company of Shelbina has been formed. Capital, $5,000. Incorporators—James M. McCreely, Henry Reinheimer, Thos. A. Gordon and others.

PUEBLO, COL.—Provided A. G. Holland is successful in his enterprise another telephone company will be operating in Pueblo before long.

CHILLICOTHE, O.—The Vigo, Richmondale, and Londonderry Telephone Company, has commenced running its line toward this city.

NORTH ADAMS, MASS.—The work of putting the telephone wires underground has begun under the direction of H. B. Emery, engineer.

INDIANAPOLIS, IND.—The Universal Telephone Company, of this city, are putting in a telephone exchange at Paris, Illinois, using over 100 of their telephones.

DENVER, COL.—The Strowger telephone system is to be tried in Colorado. The Colorado Automatic Telephone Company has been incorporated to operate in Colorado Springs.

IRONTON, KY., has caught the cheap telephone movement, and will positively put a new exchange in, to rival the Southern Bell. Rates are guaranteed at an average of $18 a year.

WATSEKA, ILL.—The Watseka telephone exchange, constructed and owned by W. H. Harry, has been put in successful operation.

OXFORD, NEB.—Telephonic communication between Beaver City and this place has been established. The line was built via Edison and covers a distance of twenty-two miles.

MINNEAPOLIS, MINN.—The Clark Telephone and Construction Company, of Minneapolis, has been incorporated with a capital of $800,000.

WATERTOWN, WIS.—The La Crosse Telephone Company has made a contract for 500 instruments and a switchboard to accommodate a like number of subscribers.

TRENTON, N. J.—The Standard Telephone Company, which is working up a scheme for cheaper telephones, has already secured through its Trenton agents, James N. Clemmer & Son, over 200 subscribers.

TOLEDO, O.—The plans for the underground conduits to be constructed by the Central Union Telephone company have been completed. They have been submitted to the city authorities and approved by City Engineer Clark and City Electrician Green.

TIOGA, PA.—A new telephone company is to be organized in Tioga County, Pa., to be known as the Tioga County Telephone Company. J. D. and A. R. Niles, of Wellsboro, are solicitors, and have applied for a charter.

PASADENA, CAL.—Manager Millard of the Sunset Telephone company has been actively engaged during the past several weeks on preparation for introducing the new express telephone system into Pasadena.

CLARKSVILLE, TENN.—The new telephone line to Dover, Bear Spring, Cumberland City and Erin and intermediate points, is a "sure go." The line will be built and controlled by the Clarksville Telephone Company and work will be commenced within thirty days and pushed to an early completion.

CAMDEN, N. J.—The New Jersey Standard Telephone Company is endeavoring to secure enough subscribers in this city to establish a service to compete with the Delaware and Atlantic Telegraph and Telephone Company. Greatly reduced rates are offered.

NORRISTOWN, PA.—Delaware and Atlantic Telephone Company officials are inspecting a route for an extension of their line from Collegeville through a half-dozen thriving villages to the boroughs of Pennsburg and East Greenville, on the Perkiomen Railroad, near the Lehigh county line.

ALTOONA, PA.—The Altoona Phœnix Telephone company has elected officers, as follows: H. Price Graffius, president; A. V. Dively, treasurer; John M. Hamor, general manager. The contract for putting in the new system has been let to the Western Telephone Construction company of Chicago.

JASPER, TENN.—The East Tennessee Telephone company is progressing very rapidly with its line of work through this section of the country, and Jasper is already in communication with South Pittsburg and Bridgeport. In a few days Victoria, Whitewell and Chattanooga will be connected.

SAN FRANCISCO, CAL.—The charter of the People's Mutual Telephone Company of California contemplates the building of long distance lines throughout the State and the establishment of a complete system of communication by telephone in the City of San Francisco.

WICHITA, KAS.—A blow has been struck here at the Missouri & Kansas Telephone Co. by the city council. The company refused to reduce the monthly tolls and the council imposed a license tax of $10 per month on each telephone, and passed an ordinance imposing $100 fine on any person using a telephone until the company pays the tax.

JACKSONVILLE, FLA.—The projectors of the Jacksonville Telephone company have organized a company which proposes to furnish the citizens of Jacksonville telephones at a cheap rate. The promoters of the new company are W. N. Shine and M. B. Rice, of Tallahassee; A. H. King, of Jacksonville, and A. H. King as trustee.

COLUMBUS, IND.—The Citizens' Telephone Company (the Harrison system) has completed and opened a large exchange here and has reduced the rate of the Central Union from $36 to $27 per annum for business houses, and from $36 to $18 for residences. The last named company has now announced an open rate of $12 for business houses and $8 for residences.

SHELBYVILLE, IND.—The stockholders of the Mutual Telephone Company have elected the following men who constitute the board of directors: D. B. Wilson, J. G. Deprez, J. D. Pugh, F. C. Sheldon and George Pratt. The directors then elected the following officers: George Pratt, president; F. C. Sheldon, vice-president; J. G. Deprez, treasurer; J. D. Pugh, secretary.

WASHINGTON, IA.—The Iowa Union Telephone Company, licensed by the Bell Telephone Company, have completed their lines to this city, opening up communication between the cities of Muskatine, Davenport, Columbus Junction and Burlington. From here the lines will be extended west, connecting the cities of Oskaloosa, Sigourney, Ottumwa and Des Moines.

PENDLETON, ORE.—The Blue Mountain Company are successfully operating their lines from Pendleton to the following places: East to the Indian agency; south to Pilot Rock, and Peter West ranch; north to Fulton, Warren, Helix station and Helix post-office. The line will be connected north to Vansycle within a few days; east to Mission within two weeks.

CAMDEN, N. J.—An ordinance has been passed granting permission to the Telephone Company, of South Jersey, to construct wires and maintain a telephone service in this city and giving the company the privilege of stringing wires on the poles owned by the city. For each pole erected the company will pay to the city the sum of 25 cents, and the company agrees to furnish all city officials with a telephone free.

DETROIT, MICH.—Charles Flowers, attorney for the Harrison Telephone Company has stated before Mayor Pingree that the company would not accept the ordinance granted it unless the rates of service were restored to $50 for business places, $40 for professional offices and $36 for the residences. As the rates now stand in the ordinance they are $40 for business places and $25 for residences.

GONZALES, TEX.—The Gonzales Telephone Company has been formed for the purpose of constructing and operating long distance telephone lines to points in Gonzales, DeWitt, Lavaca, Victoria, San Patricio, Nueces, Bee, Karnes, Bexar, Hays, Fayette and other counties in Southwest Texas; capital stock, $30,000; incorporators: Leslie P. David, A. J. Moore, H. C. Kokernot and others.

MONTICELLO, N. Y.—The Sullivan County Telephone Co., of which G. Christian is President and Captain E. H. Pinney, Secretary; Charles Homer, Treasurer, are going to extend their line to Monticello. They have now a complete system in Liberty which gives great satisfaction. They propose to place instruments in every town through the county and establish a central station at Monticello.

LONG DISTANCE TRANSMISSION AT 10,000 VOLTS.

(THE POMONA PLANT.)—III.

(*Concluded.*)

BY GEORGE HERBERT WINSLOW.

A short test of the Pomona circuit was made on April 11th, the results of which are given in Table I. A preliminary efficiency test on the San Bernardino circuit was made April 13th, 1893; variable load was obtained by the use of a water resistance.

An efficiency test of the San Bernardino circuit lasting five hours, during which the generator was kept at full load or overload, was made April 14th, 1893. Readings were taken every fifteen minutes, and the efficiencies and the corresponding voltages for different loads are plotted in Fig. 5. The most prominent feature of this efficiency curve is its irregularity. This is, however, satisfactorily explained by referring to the curve of generator voltages, on which it is seen that the high efficiencies correspond to high voltages and vice-versa.

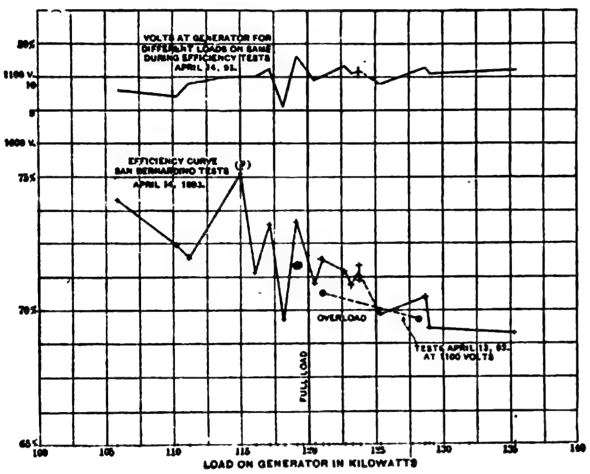


FIG. 5.

It will be noted that the apparent efficiencies shown by the preliminary test at San Bernardino agree very closely with the results of the long efficiency test there. On calculating the apparent efficiencies for different loads from data obtained by laboratory tests, and comparing them with the measured apparent efficiencies, it is found that they agree within three or four per cent. This very close agreement is exceedingly gratifying, particularly when we consider that the tests of the plant were made with ordinary commercial instruments, and that the laboratory tests were made about a year before the commercial tests.

An interesting and unique test was made May 2d, 1893, by connecting the Pomona line wires in series with the San Bernardino circuit, and transmitting about 100 H. P. to San Bernardino by way of Pomona. The length of the circuit was 85 miles, and the distance of transmission 42½ miles. This is the greatest distance yet covered by any transmission since the Frankfort experiments. The measurements are given in Table II. The apparent efficiencies are much lower than those indicated by calculations, as in the latter no account was taken of the capacity and inductance of the circuit. The voltage of the generator as measured is about 5 per cent. above that calculated, and the amperes measured notably exceed the amperes calculated. These results are attributable to the introduction of the Pomona loop, which added both capacity and inductance.

TABLE I.

EFFICIENCY TESTS. POMONA CIRCUIT.

April 11th, 1893.

Canon (20 Converters).			Pomona (18 Converters).			
Amperes.	Volts.	K. W.	Amperes.	Volts	K. W.	Efficiency per cent.
120	1100	132	105.85	919	97.28	73.7
118.5	1100	130.35	105.85	945	100.01	76 73
119.5	1100	131.45	107.4	929	99.78	75 9

In order to reduce the cost of operation, the San Antonio Company first dispensed with the sub-station attendant at Pomona after 11 P. M. This they did some time before the acceptance of the plant, after assuming the responsibility for any damage which might result. No trouble occurred and, after the acceptance (May 6th, 1893,) the same plan was put in operation at San Bernardino. After working in this way for several months, the Pomona Station was started in the afternoon and then locked up until the next morning. This arrangement was made possible by running the generator so that the lights should not be too high at Pomona, the lights at San Bernardino being kept right by the attendant with the Stillwell regulator.

In January, 1894, another 120 K. W. generator was installed with an equal capacity of oil transformers, and the Pomona and San Bernardino circuits are now each operated from separate generators with separate banks of transformers of 10,000 volts. Since this change the San Bernardino attendant has also been dispensed with, and the bookkeeper starts up in the afternoon and then locks up the station for the night, as at Pomona. The voltage of the lamps on each circuit is regulated by the engineer at the power-house, the generator pressure necessary at different loads to keep the lamps at the proper brilliancy being automatically indicated by the compensating voltmeter on each circuit. Thus after the plant is started the engineer has sole charge.

EDUCATIONAL.

APPLIED ELECTRICITY AT JOHNS HOPKINS.

One of the University Circulars of Johns Hopkins University, for 1895–6 just issued gives the syllabus of the course in Applied Electricity, and the requirements for entrance.

Especial attention is given to the electrical transmission of energy, electric traction, and alternating current work. The course includes lectures on theoretical and applied electricity and electrical measurements, with so much of mechanical engineering as seems necessary. An important feature is laboratory work, to which much attention is paid, and original investigation is especially encouraged. The instruction is given by Prof. H. A. Rowland, Professor of Physics; Dr. Louis Duncan, Associate Professor of Electricity; Mr. Hermann S. Hering, Associate in Electricity; and Mr. H. G. Geer, Instructor in Mechanical Engineering.

The course extends through two years and is intended principally for graduate students.

SOCIETY AND CLUB NOTES.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

The American Electro-Therapeutic Association, will hold its Fifth Annual Meeting, at "The College of Physicians and Surgeons, of Ontario," in Toronto, Canada, on Tuesday, Wednesday and Thursday, September 3, 4 and 5, 1895. The secretary of the Association is Dr. Emil Heuel, 352 Willis avenue, New York City.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES.

THE ANNUAL CONVENTION of the Association of Edison Illuminating Companies is now in session at the Hotel Cadillac, Detroit, Michigan. The first two days of the Convention, August 13th and 14th will be devoted to papers with discussions, together with any business which may come before the meeting. On the last day, August 15th, the delegates will be entertained by The Edison Illuminating Company of Detroit and the General Electric Company.

On account of the large number of short papers to be presented, the proceedings of the Convention promise to be particularly interesting, and as many new companies have been admitted a larger attendance than usual is present.

LETTERS TO THE EDITOR.

MUNICIPAL FIGURES AND MUNICIPAL FINES.

I have been greatly interested to note your recent comment, in THE ELECTRICAL ENGINEER of August 7, upon the statistics with which Prof. Parsons has endeavored to bolster up what I cannot but regard as the weak cause of municipal lighting. Those who are interested in electric lighting cannot have too much light let in upon data which, false in actuality and therefore doubly false in inferences drawn from it, is directed against the honest investments of private capital in central station work. Figures like those of Prof. Parsons are dangerous in more ways than one. They not only injure existing plants, hundreds of which have not yet earned dividends, but they tend to run communities into debt which is already more than some of them can stand. In addition to this, these figures prejudice the future of the art, for while private capital is generally ready to take up a new thing, I have rarely seen municipalities that have invested in one set of apparatus, on which a loan has been raised, anxious to make a further purchase, unless there is a chance somewhere in it for somebody to clean up a little for himself.

But I want just now to point out a set of figures which you critics seem to overlook in these wonderful municipal statistics. I never find in them any mention of rebates or fines for lights out. Now we all know that the "rebate" is a favorite club with many city officials to wield on the head of the poor local company, and that the rebate is frequently insisted upon when the shortcoming of the service is not due to any lack on the part of the company. Take the rebate charges applied to local plants and add them on to the municipal plant figures, and you would again discover the absurdity of the low figures quoted. My own impression is that because the city cannot very well fine itself, the laxity is often greater than a private plant could possibly afford, no matter how high a rate it got per light.

Then the "racket" of asserting that lights are below candle power, and withholding warrants for payment on that account is another little dodge that is worked on the local company. The municipal lights I have seen have certainly been far more open to suspicion on this account than private lights, but what does it matter, unless a political question can be made out of it, or a chance is offered to behead an official and get some other man in for a share of the plunder?

J. B.

LONG ISLAND, Aug. 9, 1895.

ECONOMY OF CONSTANT POTENTIAL ARC LIGHTING.

IN reply to a communication in your issue of the 7th inst., by Mr. W. N. Stewart, in re the "Economy of Constant Potential Arc Lighting," I must admit at the start, that my statement made in my communication in your issue of the 17th of July last, in which I said, "so far as the question of economy is concerned, the constant current system is far the more economical whether looked at from the point of view of a complete electrical installation or from that of the amount of energy consumed by the lamps in producing a given amount of light," was too broad and should have been made more specific

It was not my intention to make a comparison between the constant potential system, installed, as is usually the case, for the purpose of running incandescent lamps and as an auxiliary constant potential arc lamp, and a constant current system installed as it usually is for the sole purpose of running constant current arc lamps. I should have stated that the comparison, so far as the systems were concerned was between a constant potential system intended *only* for running arc lamps and a direct current system for the same purpose. This was implied in my communication but was not so specifically stated.

I still think that with this view of the case, the direct current system will have the advantage over the constant potential system, both in economy of first cost of plant and economy of operation. The great advantage which the constant potential system has is its flexibility and the ease with which any form of translating device can be operated upon it, and when used in this way it is undoubtedly the most economical system of distribution and translation which we have. But I doubt if any one would deliberately lay out a system of constant potential distribution for the sole purpose of running arc lamps and nothing else, and it was from this point of view that I made the statements which I did, and which I still believe to be correct, namely, that "on the constant current system, the cost of a complete installation for a given number of *arc* lamps distributed over a given area is much less than for a corresponding number of *similar* lamps operated on the constant potential system." And further, that "so far as the economy in the operation of the lamps is concerned the direct arc lamp is the most economical for a given amount of light on account of the great amount of power which has to be wasted in the dead resistance which has to be used with the lamps when operated on a constant potential circuit."

E. R. KNOWLES, E. E.

LEGAL NOTES.

TROLLEY RIGHT OF WAY IN NEW JERSEY.

Chancellor McGill of New Jersey has decided that the securing by an electric railroad company of right of way along a turnpike does not empower it to build a road there without permission of property-owners and township authorities. In the case in question, a highway between Red Bank and Eatontown, in Monmouth County, was formerly owned by a turnpike company, but was abandoned in 1891. Two years later the charter of the turnpike company was repealed by the Legislature, with the proviso that permission be given to operate a trolley road there. On the same day an act was passed designed to apply to the case, and granting to "any corporated company the right to construct roads on the turnpike in second-class counties under certain conditions." On this authority the electric railroad company tried to go ahead without regard to the requirement of the law of 1894, that the consent of the majority of the property-owners should be obtained. The Chancellor restrains the company from building the road without the required consents of the abutting property-owners and of the Township Committee, and the company can now set about getting those permissions.

THE BELL COMPANY SUES UNDER THE BERLINER PATENT.

The first suit brought by the American Bell Telephone Co., under the Berliner patent, recently sustained by the United States Circuit Court of Appeals, has been brought in Boston, against the National Telephone Manufacturing Co. The Bell Company asks for an injunction on the ground of infringement. The first hearing has been set for September 2.

LITERATURE.

Transactions of the American Institute of Electrical Engineers. Vol. XI. Cloth. Illus. 938 pp. Published by the Institute, 1895.

This large volume is certainly one of the best ever issued by the Institute; in fact we do not recall a better one in the series that now reaches such respectable dimensions. The contents are familiar to electrical readers, having appeared from time to time in the journals as well as in the admirable monthly record. We are very glad to see along with the discussions in New York, those in Chicago, which are a decided gain and will, we hope, soon be reinforced by the discussions in other local centers. Besides the papers and discussions, the volume contains careful indexes, lists of members, and a really fine portrait, one of the most faithful we have ever seen of Past President Frank J. Sprague. Altogether the volume is most creditable to the Institute, and a trustworthy pledge of its high purposes and aims.

WHEN TO DEVELOP A WATER POWER.

WRITING in *Cassier's Magazine* for August, Mr. Samuel Webber says: Persons owning desirable water powers need not be afraid to develop them, if coal costs over $2.00 per ton at the site; but in laying them out they should be governed by the minimum reliable flow of the stream, plus the amount that can be saved by night storage if it is only to be used for power by day, or for lighting by night, as such storage will double it. You may calculate on getting 80 per cent. net effect, with either of half a dozen of the best turbines, say the Geyelin, Hercules, Humphrey, Hunt, Leffel, Risdon, Swain or Victor, all of which have shown higher records than 80 per cent. With this effect you can get a horse-power net for each cubic foot of water per second on an eleven-foot fall. Do not, however, as the writer has seen done, plant a mill requiring 300 horse-power on a stream which would furnish only 100 horse-power for six months in the year, and have to haul coal from the railroad three or four miles distant to supply steam for the balance.

So much for the cost of water-power. For its value, I return to the old rule. It is worth, in any place, if it should be needed at all, what it will cost to replace it by steam, and for this find the cost of coal per ton delivered at your boilers.

For triple compound engines allow 1.50 pounds of coal of best quality per hour per horse-power, or, to be safe, say 1.75 pounds; for double compound, 2 to 2½ pounds; for single condensing, 2½ to 3 pounds; or high pressure, 3 to 3½ pounds, according to size of engine.

To the cost of fuel add wages of engineer and fireman, cost of oil, and 12½ per cent. on the cost of the plant for sinking fund, for renewal, interest, insurance and taxes, repairs and supplies, and you get pretty close to the cost of a horse-power of steam as representing the only known measure of the value of a horse-power of water.

ELECTRICITY IN DENTISTRY.—CONVENTION OF THE NEW JERSEY STATE DENTAL SOCIETY, AND THE AMERICAN DENTAL ASSOCIATION AT ASBURY PARK.

The annual meeting of the New Jersey State Dental Society, and that of the American Dental Association, which were held last week at Asbury Park, were of special interest from the fact that in the papers and exhibits evidence was afforded that the province of electricity in dentistry is rapidly increasing.

Dr. William L. Puffer, assistant professor of electrical engineering at the Massachusetts Institute of Technology, read a valuable paper on "The Electrical Principles Applicable to Dentistry"; and Mr. A. E. Woolf gave a paper on the general utilization of his system for the electrolytic decomposition of a chloride solution. This paper told of what had been accomplished by the system, its application to the treatment of germs and diseases caused by germs; and the difference in the action of coagulants on organic matter and lower forms of germ life. Illustrations were given on the screen of the difference in the action of various disinfectants and the decomposing power of Mr. Woolf's electrozone.

An interesting electrical demonstration was made by Dr. Charles A. Meeker, of Newark, N. J. Dr. Meeker bleached several teeth at once in different chairs by cataphoresis. Pyrozone was used in conjunction with an "adapter," using 110 volts.

Dr. Meeker explained that in order to accomplish the bleaching of several teeth of different patients at the same time, it is positively necessary that the teeth so presented should be free from loose decay pulps, and without nickel, amalgam, or plastic cements.

Dr. Henry W. Gillette's paper on "Electrotherapeutics of Obtunding Sensitive Dentine," was one of the most valuable communications of the convention.

Prominent among the exhibits was that of the Edison Manufacturing Company, who showed a compact and workmanlike dental plant. The exhibit, which was supervised by Mr. H. H. Shrope, consisted of a suspended dental motor, running from eight cells of Edison-Lalande battery of 500 ampere hour capacity, and 5½ volts. It is estimated that this cell will last the dentist, with a fair average amount of work, from nine months to a year. The motor reverses and, by means of a foot switch, can be made to stop instantly. As showing the capability of the motor, it is claimed that it can develop enough power to break the shaft. On the same circuit is worked a noiseless sick room fan, dentists' mallets, and miniature lamps for translumination. The exhibit included the Kennelly adapter, for use with the 110 volt Edison street circuit. This is a very beautiful instrument. It has a rheostat of German silver wire, 80 windings to the inch. It can be used for galvanic, pulsatory galvanic, and the different kinds of faradic current. One of its special features is the Kennelly amperemeter, which has been recommended by the American Electrotherapeutic Society at its last three annual meetings, as the best instrument for the physician. The Kennelly step-down transformer was also on exhibition. This is a compact device for using the alternating current for cautery work, miniature lamps, and for translumination. The step down is from either 52 or 104 volts, to 4 volts, and about 18 amperes. The Edison family and physician's faradic batteries, the cells of which give constant current, with no action of the cell except when the switch is turned, were also shown.

The W. J. Davis Electric Company, of Pittsfield, Mass., showed an alternating current motor for dental purposes, with rheostat for starting and reversing. The motor was suspended on a flexible cable, and connected direct to the armature shaft, the starting and stopping treadle being placed on the floor. The Custer electric furnace for dental work made an interesting exhibit. The Dental Protective Supply Company, of Chicago, used a Lundell motor for driving its wall bracket connecting engine.

The exhibit of the Electrotherapeutic Company, of New York, was conspicuous beyond the general excellence of construction apparent, from the fact that it contained a large number of novelties. Most of these are due to the ingenuity of Mr. G. M. Wheeler, the electrician of the company. The noiseless reversible motor, with instantaneous magnetic stopping attachment for operating dental engines attracted much attention. The disagreeable humming sound attending the action of some motors, was entirely absent. Other points in its favor are its steady power at all speeds, reversible and instantaneous stopping attachment. The action of the motor is controlled by a new treadle connecter. This is usually placed on the floor at the base of the operating chair, connections of flexible cord allowing its movement around the chair. By the action of the operator's foot on the treadle connecter the motor is run right-handed, left-handed, or instantly stopped. When started, the motor continues running until the heel of the connecter is pressed. This arrangement allows the operator to remove his foot from the treadle connecter and working from any position, to concentrate his attention on the work in the patient's mouth. The speed of the motor is varied by means of a rheostat provided with a switch arm sliding under ten contact pieces, giving as many variations in motor speed. As the motor was equipped with a 3-sized pulley, the number of variations ran from 300 to 4,000 revolutions per minute. In the extension dental engine, the bracket arm is made of aluminum, and its lightness created a pleasing impression. It is used for carrying the engine head of the dentist; it is 35 inches when closed, and 58 inches when extended to its full length.

The most notable feature of the Electrotherapeutic Company's exhibit was its current adapter, for regulating and controlling the street circuit current for galvanic and faradic current application; it is specially adapted for cataphoric work. The difficulty with this current has always been in regulating the voltage so that it could be so gradually increased as to cause no inconvenience in the mouth of the patient. This sudden abruptness of the change from one voltage to another has long been the bugbear of dentists. It consists of a nickel plated brass cylinder, 16 inches high, with a base diameter of about 6 inches. Its fibre head carries screw posts, a switch for turning on and off, and an index, which enables the operator to have always in sight the exact voltage with which he is operating. The needle which passes over the graduated scale of the index, registers up to 100 volts. The capacity of the machine is 500 milliamperes at maximum pressure of 100 volts. The gradations in current voltage are as fine as $\frac{1}{1000}$ of a volt, so that the increase is not perceptible to the patient. Speaking generally, there are two ways in which this instrument can be applied: First, locally. This application is made from a double pole electrode, having rubber cups in which cotton saturated with the obtundent, presumably cocaine, is placed. This electrode is so made that the rubber cup fits on each side of the gum surrounding the teeth. The current traverses from one rubber cup, through the gum, to the cup on the other side of the gum. With the passage of the current, the tooth nerve is anæsthetized. The tooth is then ready for extraction, or excavation, as the case may be. It is in the starting of the current that the peculiar advantage of the current adapter enters. It is started from zero and run up so gradually to, say, $\frac{1}{500}$ of a volt, that the patient does not know it is being applied. It is then raised, in waves instead of steps, to $\frac{1}{100}$, $\frac{1}{50}$, 1 volt, up to, say 12 volts, giving the average maximum current. By the time the patient has thoroughly realized that the current is doing work, the work is over. This period may be from 1 to 5 minutes according to the size of the electrode, and the temperament of the patient. The resistance of some persons to the flow of the electric current is remarkable, as doctors who are employed to watch the effect of the lethal shock at electrocutions, can testify.

The second application of the instrument is as follows: A needle-holder electrode carries a platinum needle; this electrode, used as a positive pole, is applied to cotton, saturated with cocaine with which the cavity of the tooth is filled. The negative electrode, which is the common sponge, is held at the point of the jaw on the side of the face on which is the tooth being operated upon. When the current is turned on it traverses from the needle electrode through the saturated cotton, through the dentine and apex of the tooth, and to the outer surface of the cheek, where the negative electrode is applied. These are the two principal methods in which it has been found feasible to apply this new and humane process, to the description of which and its possibilities Dr. H. W. Gillette devoted the whole of his able paper.

The new cataphoresis in dental work includes the application of pyrozone for the bleaching of teeth. This is done in the same manner as the deadening just described, with this difference, that instead of an anæsthetic, pyrozone, a commercial form hydrogen dioxide, which has powerful bleaching qualities, is used. An important device in this exhibit was the Freeman electric hot air syringe, a description of which was embodied in a paper by its inventor, Dr. S. Freeman, of New York, on "Compressed Air Apparatus in Mechanical and Operative Dentistry." This syringe is used with either compressor tank or a hand bulb, which the operator can work himself. The heating of the air is effected electrically. About half way down the syringe, within touch of the thumb, is a switch, for starting and regulating the current, which passes through a resistance attached to the syringe. An intense heat can be secured in this way; 600 degrees Fahr. have already been measured; and it is claimed that 1,000 degrees can be reached, if necessary. The syringe is used for anæsthetizing, disinfecting, or bleaching the teeth. The tooth contains about 10 per cent of water, and it has been demonstrated that when this water is removed, the normal tooth function of transmitting impressions is impaired. Such dessication is usually accomplished by heat, cold, or chemicals: Dr. Freeman finds that heat is the best. In anæsthetizing by this method, the root canals of the teeth are first dried by the stream of electrically heated air, and then the material is sprayed into the tooth, or forced through the tissues at a high pressure. In the bleaching of teeth the required conditions for the operation can be produced in one-half the usual time by the application of hot air at a high pressure, which rapidly evaporates the pyrozone, and forces it into the tubuli.

In this exhibit the Phillips electric headlight, for direct illumination was shown. Like the ordinary surgeon's headlight, it is

fitted to the head with a spring clamp; but it has, in addition, an adjustable lens, which brings the light to a focus, or diffuses it, at the will of the operator. It also has a universal joint, which throws the light at any angle, and greatly increases its efficiency. A special transformer was exhibited, made on the same principle as the ordinary transformer; but whereas the ordinary transformer is built, say, for 1,000 volts, and steps down to 50 or 100, the Wheeler device takes in the current at 53 or 104 volts, and transforms it to from 2 to 8 volts. It is specially used for cautery work, small mouth lamps, and for general faradisation. Mouth lamps, for examination and translumination of the antrum, batteries, fan motors, electrodes, and general supplies for surgical and dental work, made up an exhibit of exceptional merit.

The convention was a great success and the energy and administrative ability of the officers of the New Jersey Society were very much in evidence. Dr. Charles A. Meeker, its secretary, provided an admirable programme pamphlet for the guidance of the members, and Dr. Harvey Iredell, of New Brunswick, of the executive committee, earned the gratitude of all the exhibitors by his indefatigable efforts in their behalf.

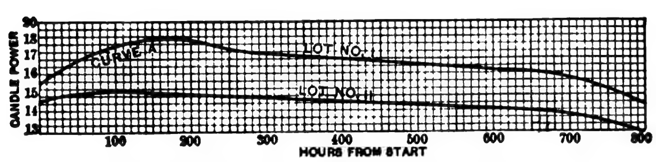
TEST OF PACKARD LAMPS.

BY PROF. B. F. THOMAS.

We have received from the New York & Ohio Co. a report of an exhaustive test of Packard lamps, made by Prof. B. F. Thomas, of the Ohio University, which will prove of interest to all users of incandescent lamps.

In order to test the lamps under commercial rather than laboratory conditions, arrangements were made with the local Edison Electric company to carry on the test on their regular circuit where the lamps would be subjected to the same variations in voltage that they ordinarily experience in practice.

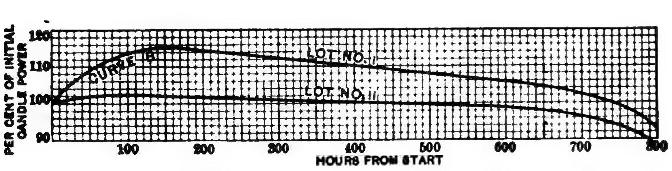
Fifty 100 volt 16 C. P. lamps were tested in two lots of 25 each. The average voltage was about 99. The photometric readings were taken with a Lummer-Brodhun photometer. The values obtained are plotted in the accompanying diagram, curve *A* showing the



CURVE "A," SHOWING CANDLE POWER.

candle power and time; curve B the percentage of initial candle power and time, and curve C the efficiency and time.

As shown by these curves, Lot I shows a marked increase in candle power on the start, reaching a maximum of 17.9 candles at about 175 hours, then decreases uniformly until 600 hours, when a more rapid decrease sets in. The candle power does not fall to its initial value of 15.54 candles until over 700 hours from the start. Lot II shows only a moderate rise in candle power, with a maximum at about 150 hours, and then decreases uniformly to its initial value at 400 hours. It shows also a sharp increase in declining brightness at 600 hours. This change may have been pro-

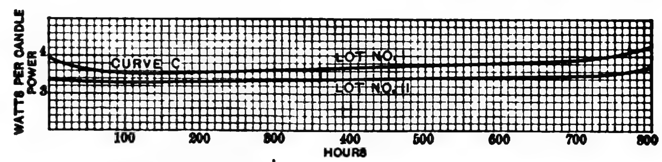


CURVE "B," PER CENT. OF INITIAL CANDLE POWER.

duced by strain due to abnormally high voltage at soon after the 600 hour point. Such a high voltage was observed for some time during the day preceding the evening on which the readings at 696 hours were taken, and its effect on the candle power of Lot I was particularly marked, though less so than on Lot II. Curve *B* shows a rise of over 15 per cent. in the candle power of Lot I, with a final value only 6.5 per cent. below the initial value. The total range in candle power from beginning to end, is 23 per cent. for Lot I, and 14.5 per cent. for Lot II.

Curve *C* shows a marked increase in efficiency for Lot I on the start, falling back to the initial value only after 600 hours. Lot II improves in efficiency also on the start, though to a smaller extent, and continues at a practically uniform figure for 600 hours. The decrease in efficiency of each lot after 600 hours is much less rapid than usual. Curve *D* shows the candle power per watt.

With the tests as a basis, computations were made as to the economy of the lamps. For this purpose the cost of the lamp was assumed at 20 cents and that of the kilowatt-hour at 20 cents. Under the conditions assumed the lamps in Lot I show a minimum average cost of the light produced by them, under the conditions assumed, at about 450 hours. Lot II shows a minimum, under the same conditions at 650 hours. The difference in cost of light produced by the two lots, at the minimum point for each lot, is about 7 per cent. in favor of Lot II. The range in candle power

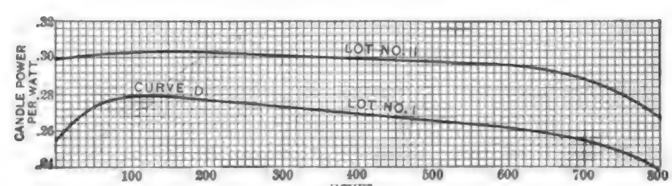


CURVE "C," WATTS PER CANDLE POWER.

of Lot I, up to 450 hours, is about 15 per cent., while that of Lot II is only 6½ per cent. up to 650 hours. Lot II is better than Lot I on this account also, as uniformity of candle power is desirable, other things being equal.

The prices used were chosen because they fairly represent lamp cost, and cost of energy as supplied by central lighting stations in this country to-day. Higher prices for lamps, or a lower price per kilo-watt hour will bring the "smashing point" for either lot later than the times named, though no change in the relative value of the two lots will follow, if compared under like conditions.

For isolated plant work, the net cost of energy is considerably



CURVE "D," CANDLE POWER PER WATT.

decreased, and may be taken at less than ten cents per kilo-watt hour—in some cases as low as six cents. For such work, the computed cost will show a minimum at or beyond 800 hours. The "smashing point" will in some cases not be the question of cost of light produced, but the decrease in candle power of the lamps being reached when the light produced by the lamps is no longer satisfactory. No lamp of either lot showed any serious blackening, and the majority of the lamps were scarcely blackened at all.

Taking economy, maintenance of candle power and freedom from blackening into account, the results obtained from these lamps according to Prof. Thomas are much superior to any heretofore published.

INFLUENCE OF ELECTRICALLY DISSOLVED GAS ON DEPOSITED SILVER.

The current number of *Wiedemann's Annalen* contains a paper by Herr J. E. Myers on the influence of gases dissolved in the electrolyte of a silver voltameter on the weight of deposited silver. The author finds, says *Nature*, as has previously been shown by Schuster and Crossley, that if the same current is sent through two voltameters containing neutral solutions of silver nitrate of the same strength and at the same temperature, one voltameter being in a vacuum, and the other in air, then the weight of the silver deposited in the vacuum voltameter is, for a solution containing from 20 to 40 per cent. of silver nitrate, about 0·1 per cent. greater than that of the silver deposited in the other voltameter. For a 5 per cent. solution the difference is somewhat smaller. If the solution is saturated with carbon dioxide, the deposit is about 0.055 per cent. lighter than when the solution is saturated with air. With nitrogen, however, the deposit is about 0.05 per cent. heavier than with air. The electrical resistance of a 5 per cent. solution saturated with air is practically the same as that of the same solution in a vacuum. With a current of more than 0.25 ampere it is found that in vacuum an evolution of gas takes place at the anode. The author has also examined the grey deposit which is formed on the anode, and finds that it consists of pure silver oxide.

"THEORETICALLY PERFECT AND PRACTICALLY USEFUL."

Mr. Edward E. Higgins, the well-known expert in street railway values and economies, writes: "I want to congratulate you very heartily on your new plan for issuing Data Sheets as a Supplement to the Engineer. I cannot see why this plan is not theoretically perfect and practically useful to a very high degree, and I shall look forward with much interest to receiving them from time to time. Please send me a filing case in morocco."

VOL. XX. NEW YORK, AUGUST 14, 1895. No. 380.

CONTENTS.

CENTRAL STATION TENDENCIES.

THE interesting paper read by Mr. Franklin L. Pope at the Niagara meeting of the American Institute of Electrical Engineers, aside from the intrinsic value of the information it contained has still another merit in that it signalizes the fact that we have, as it were, reached a period of transition in central station practice, and that if profits are to be derived in the future, from central stations, methods will have to be adopted differing radically in many respects from those which have been considered standard in the past. While Mr. Pope's paper dwelt specifically on the changing over from a low tension direct, to a high tension alternating system, the deeper question involved in such work and in all new central station equipment, is the manner in which the generating plant shall be divided and the character of such units. The earning capacity of a station must depend largely, first on the economy of the apparatus, and secondly on the extent to which the investment involved is utilized. In discussing this side of the question in an able communication appearing in the *Railroad Gazette*, Mr. George W. Blodgett, offers the following as a means for increasing the earning capacity of a station, where there are no limiting conditions: 1. Distribute the demand for electric current uniformly over the 24 hours of the day, by transferring the excessive requirement to some portion of the day where now there is power to spare. 2. Accumulate a surplus when the plant is not taxed to its full capacity, to be drawn upon during the hours when the demand exceeds the limit of the average supply. 3. Furnish the difference between the average and the maximum requirements from a part of the plant costing less than that portion which is constantly in use.

These are sound principles, which we think will be acquiesced in by all central station engineers, but the specific means for carrying them out will probably still call for variations of the most pronounced type. Mr. Blodgett is strongly inclined to the use of the storage battery as the ideal means for carrying out the above arrangement and in this he reflects the opinions of some of the most advanced electrical engineers both here and abroad. The storage battery has certainly had a marked effect on central station work and we think we can discern its influence in a gradual tendency to return to the smaller engine unit. This again has had a reflex action on the type of engine employed in central station work and a striking example of this is offered in the description of the new Belfast station, which we print elsewhere in this issue. Here the gas engine has been applied in a manner which American engineers will do well to study closely. The high efficiency of the gas engine and the low cost at which producer-gas can now be made must secure for this type of engine a broader recognition than has yet been accorded to it.

But has the last word been said on the steam engine question in central station work? Much has been done towards bringing up the economy by the introduction of direct connected multi-cylinder engines, but recent developments point to a new and, we think, revolutionary departure in central station steam engine practice. We refer to the introduction of the steam turbine in this class of work and we need not go far to show that the turbo-generator possesses qualities which pre-eminently fit it for this particular duty. Leaving out of consideration the fact that the

steam turbine requires practically no foundation, its freedom from vibration fits it not only for central stations located in populous centres, but adapts it particularly for isolated work. But the great advantage of the steam turbine manifests itself in the fact that it occupies about one-third the height and but one-half the floor space occupied by the most compact inverted engine with direct coupled multipolar dynamos. As regards steam consumption, again, the turbo-generator can easily hold its own with the best multi-expansion condensing engine at full load, while it can do better at light loads. The tests of Professor Ewing on these points must be considered conclusive. To all these advantages must be added the reduced cost of the steam turbine and generator which can be built for about two-thirds the cost of a direct-connected multipolar unit of equal capacity. The high rotative speed of these engines will also bring us back again to the bi-polar dynamo for direct current and will reduce the number of poles for alternating current work to almost the same number. England has taken the lead in the introduction of the turbo-generator and the results obtained in that country with the Parsons steam turbine are most encouraging. It will not be long, however, before we will also be able to judge of the merits of this type of engine from actual experience on this side of the water. As has been its custom from the very start, the New York Edison Company will again do yeoman service by introducing the De Laval steam turbine into its new 12th St. station, now in course of construction, two 300 H. P. machines having been ordered for that purpose. As the station is also designed for storage battery work there will thus be afforded a fine opportunity for study and comparison of results on two points in central station practice on which American engineers are looking for additional light.

ELECTRIC LOCOMOTIVE BUILDERS.

Some months ago, discussing the changes that had then begun to make themselves apparent in the motive power of short railroads and the new conditions forced on extensive railway systems by trolley competition, we ventured to predict that at a very early date one or more of the large builders of steam locomotives would find it to their interest to engage in the work of building large electric locomotives. It was, however, hardly to be expected that the new departure would be made with the speed which is now apparent in the important news published within the last few days ; and we can only suppose either that a long study has been quietly made of the subject in unsuspected quarters, or that the revolution has come with a rush that necessitated an immediate dealing with it. Perhaps a significant incentive may be found in the remarkably small demand that has existed during the last three years for locomotives of any class, compelling observant manufacturers with large plants to cast about briskly for fresh opportunities of activity and profit.

Be this as it may, the announcement that the Baldwin Locomotive Works have joined forces with the Westinghouse Company is to be received with pleasure as one of the first signs of the new era to which some of us have looked forward. The working arrangement appears to have been shrewdly planned, and should prove easy to live up to. It is certain that no locomotive concern could plunge to-day into the middle of things electric without running the risk of serious loss from mistakes, misinformation and infringement suits ; while, on the other hand, electrical manufacturing companies have much to learn in the locomotive field and would just now have great difficulty in securing the capital for another branch of industry. We confess our preference for specialization of product, and do not believe that the electrical arts will ever reach their best until each group of products and even each article is turned out by a separate concern whose whole prosperity and future rests upon the excellence and real cheapness of its goods. The Westinghouse Company has been wise, magnificently equipped though it be, to abstain from attempting directly the execution of such heavy and difficult work as that of locomotive building.

The Baldwin Locomotive Works have always shown themselves appreciative of electrical advances, and have already done some interesting work for electrical inventors. They were among the very first of the large industrial companies to equip their shops with electric power, and lately have been adding to their plant which, if we remember aright, exceeds 400 H. P of motors in some 25 units. It is very fortunate that at the outset of electric locomotive building electricians can draw on the unsurpassed and prolonged experience of such a company, and we now look for rapid and solid advance. The action of other locomotive builders, under the circumstance, will be attended with peculiar interest.

THE BERLINER PATENT AGAIN IN COURT.

WHATEVER the opponents of the Bell Company may lay at its door they certainly cannot accuse it of chicken-heartedness, and the promptness with which it has brought suit against an alleged infringer of the recently sustained Berliner patent is proof that the Company does not care to leave itself open even to the suspicion of laches. The bringing of the suit against the National Telephone Construction Co., seems to indicate pretty clearly, either that the Bell Company does not anticipate that the Government will succeed in bringing its case before the U. S. Supreme Court, or, that if brought before that tribunal, the result will be changed. In this view we believe, they are supported by the opinion of some of the best independent legal authorities in the country. But we doubt whether the Bell Company enters upon this contest with the confidence with which its past uniform victories might well inspire it. It will be recalled that in its decision, the Circuit Court of Appeals considered only a single point among those brought forward on appeal, namely, the right of the Government to cancel a grant issued in good faith by its own officials. On this point the Court set itself squarely on record, denying the proposition in toto and hence making it unnecessary to consider any other contention looking to the invalidating of the patent. The Court expressly refrained, however, from passing an opinion on the bearing of the prior Berliner patent. On this point it will be remembered Judge Carpenter was specific, deeming the Berliner patent in controversy void on the same grounds that underlie the celebrated *Miller v. Eagle Mfg. Co.* decision.

There can be but little doubt that this will constitute the main defense in the present suit. That the telephone manufacturers are not dismayed is evidenced by the organization of another mutual protective association in the East, of which we give the details on another page. At the same time the recently organized Telephone Protective Association of America is at work and it is more than probable that one or both these associations will undertake to defend the case either directly or intervene as co-defendants.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUG. 6, 1895.

Accumulators:—

Machine for Making Battery Plates, Thomas T. Lewis, Philadelphia, Pa., 544,180. Filed March 23, 1894.

Alarms and Signals:—

Fire-Alarm, Charles F. Schofield, Bridgeport, Ala., 543,896. Filed Aug. 16, 1894.

Car-Signal, Joseph S. A. Bohn, Washington, D. C., 543,955. Filed Nov. 6, 1894.

Electric Alarm-Lock for Tills, Charles Helm, Indianapolis, Ind., 544,294. Filed April 23, 1895.

Automatically Operated Fire-Alarm, F. K. Ludlow, Madisonville, Ohio, 543,879. Filed Dec. 18, 1894.

Electric Signal for Railway Trains, J. C. Henry, Westfield, N. J., 543,983. Filed April 20, 1895.

A signal is made on the locomotive by opening any one of the gates, and another signal is made when all of the gates are closed. Designed for elevated railroads.

Electric High or Low Water Alarm, B. McCabe, Boston, Mass., 543,965. Filed Dec. 15, 1894.

A float operates a signal device.

Circuit Closer, W. Nutt, Crawfordsville, Ind., 543,966. Filed Nov. 6, 1894.

A track instrument for railway signals.

Fire-Alarm Signalling Apparatus, G. W. Brown, West Newbury, Mass., 544,084. Filed Sept. 1, 1892.

Magneto-Electric Bell, L. Moore, Brooklyn, N. Y., 544,107. Filed April 11, 1895.

Mechanically assists the movement by increasing the momentum of the stroke.

Electric Signalling System, C. A. Rolfe, Chicago, Ill, 544,123. Filed Jan. 8, 1895.

Embodies a street box controlled from a building.

Conductors, Conduits and Insulators:—

Method of Connecting Ends of Electric Conductors, J. T. Beswick, Brooklyn, N. Y., 543,919. Filed Feb. 9, 1895.

The ends are notched.

Electrical Conductor, G. Gray, Boston, Mass., 543,960. Filed Dec. 14, 1894.

An anti-inductive conductor consisting of a wire grooved spirally in opposite directions.

Distribution:—

Controlling Phase Relations, C. P. Steinmetz, Lynn, Mass., 543,907. Filed Sept. 9, 1893.

A phase controller coupled in circuit so as to accelerate or retard the current relatively to the electromotive force, and a regulator responsive to changes in current strength for varying said accelerating or retarding influence.

System of Electric Distribution, E. Thomson, Swampscott, Mass., 543,950. Filed June 28, 1894.

Consists of a compensating coil, an impressing circuit connected thereto, and impressed circuits fed therefrom, the connections from the impressed circuits overlapping each other.

Dynamos and Motors:—

Alternating Current Motor, E. Arnold, Zurich, Switzerland, 543,836. Filed Oct. 9, 1894.

Controls the flow of induced currents in the armature at starting, thereby producing poles and giving initial rotation to the armature, and thereafter short-circuiting the individual coils of the armature.

Short Circuiting Device for Stopping Dental Motors, F. N. Denison, Toronto, Canada, 543,855. Filed Oct. 9, 1894.

Construction of Armatures for Dynamo-Electric Machines, W. B. Sayers, Bearsden, Scotland, 543,895. Filed August 16, 1894.

Method designed to secure equal lengths of the armature coils.

Safety Electric Motor, W. R. Polk, Jr., Atlanta, Ga., 544,118. Filed Feb. 20, 1894.

Automatically cuts off the current upon its exceeding a predetermined safe point; also utilizes part of the coils of the field magnet for the variable resistance in the armature circuit.

Alternating-Current Motor, R. Lundell, Brooklyn, N. Y., 544,261. Filed Oct. 22, 1894.

An alternating motor dependent for its action upon the angular disposition of the inducing coils, said angular disposition being such that successive poles of like polarity are established slightly in advance or to one side of the poles of the field magnet and armature coils.

Electrometallurgy:—

Vessel for Electrolytic Separation, W. Borchers, Duisburg, Germany, 544,-158. Filed Dec. 31, 1894.

Refers to a vessel in which the electrolytic separation of a metal shall take place with the simultaneous alloyage of such metal with another metal in a molten state. The inner wall of the vessel is formed with horizontal grooves and projections.

Galvanic Batteries:—

Electric Battery, R. McL. and A. McDonald, Dalmuir, Scotland, 543,885. Filed Nov. 13, 1894.

Details of construction.

Primary Battery, G. H. Gardner, Boston, Mass., 543,931. Filed July 5, 1894.

In placing the zinc element into the cell, an automatic connection is made.

Lamps and Appurtenances:—

Electric-Arc Lamp, C. E. Scribner, Chicago, Ill., 543,900. Filed March 12, 1891.

A double lamp with polarized magnet to prevent the lamp burning when current is in the wrong direction.

Incandescent Conductor for Electric Lamps, T. A. Edison, Menlo Park, N. J., 543,985. Filed August 7, 1882

Composed of carbonized unstructural cellulose or other carbo-hydrate.

Process of Treating And Products Derived From Vegetable Fibres, T. A. Edison, Menlo Park, N. J., 543,986. Filed Oct. 20, 1882.

The transparent or translucent flexible material formed by treating vegetable fibre with hydrofluoric acid.

Filament for Incandescent Lamps, T. A. Edison, Menlo Park, N. J., 543,987. Filed Oct. 20, 1882.

Treated before carbonization with hydrofluoric acid.

Electric Arc Lamp, J. A. Mosher, Chicago, Ill., 544,066. Filed May 11, 1895.

The electromagnet is so proportioned that the counter electromotive force developed by it in the main line is approximately equal to the electromotive force of the service current. Intended for alternating lamps.

Measurement:—

Electric Meter, J. Harris, Lynn, Mass., 543,865. Filed Oct. 4, 1894.

Claim 1. The combination with a pressure coil and a motor, of a torsion spring connected to said coil and to said motor, whereby the torsion of the spring automatically balances the torque of the coil.

Miscellaneous:—

Store Service Apparatus, Harry M. Neer, Springfield, Ohio, 544,002. Filed Sept. 10, 1894.

Electric Temperature-Controlling Device, S. A. Ekehorn, Milwaukee, Wis., 543,929. Filed May 1, 1894.

The valve is controlled by an electric motor controlled by a thermostat one section of which is convoluted.

Electric Condenser, C. S. Bradley, Avon, N. Y., 543,978. Filed May 11, 1895.

A polyphase condenser comprising a series of conductive plates connected in groups with polyphase terminals, the members of said groups being interleaved with one another.

Temperature-Regulator, G. H Underhill and E. Glantzberg, Boston, Mass., 544,015. Filed Nov. 17, 1893.

Visual Indicating Device, C. C. Bramwell, Hyde Park, Mass., 544,034. Filed Oct. 18, 1894.

Details of construction.

Electric-Lighting System, E. F. Gavin, New York, N. Y., 544,084. Filed Sept. 28, 1894.

Relates to illuminated advertising signs.

Apparatus for Stopping Engines, G. W. Brown, West Newbury, Mass., 544,085. Filed June 3, 1895.

Automatically shuts off the steam when the steam pipe breaks.

Medical Induction-Coil, J. Tatham, Philadelphia, Pa., 544,266. Filed Oct. 15, 1891.

The current controlled by the switch may be either a primary current, a secondary current, or a combined primary and secondary current.

Railways and Appliances:

Electric Car-Brake, G. B. Damon, Lowell, Mass., 543,544. Filed April 9, 1894

A system of pneumatic brakes for electric railroads, which may be operated from the main controlling stand by the same handle which controls the car motors.

Electric Brake-Shoe, W. B. Potter, Schenectady, N. Y., 543,653. Filed March 30, 1895.

So constructed that it can be conveniently located about the car axle without removing the car wheel.

Construction and Operation of Electric Railways and Tramways, I. W. Heysinger, Philadelphia, Pa., 543,867. Filed April 11, 1892.

Passes hot air or steam through pipes close to the rails and the underground conductors.

Rheostat Controller, C. Landers, Tacoma, Wash., 543,963. Filed March 27, 1894.

Details of construction of a car controller.

Converter System for Electric Railways, T. Harper, New Brunswick, N. J., 544,037 Filed June 29, 1894.

Improvements in the primary coils and their cores, and the secondary coils, whereby permanently and always closed solid magnetic circuits may be utilized, the axes of the primary coils being parallel with the track.

Conduit System for Electric Railways, J. and W. R. Thomas, Catasauqua, Pa., 544,056. Filed Dec. 6, 1894.

Details of construction.

Trolley Wheel, J. Conway, Baltimore, Md., 544,157. Filed Jan. 4, 1895.

Electric Railway, F. Taylor, Charlotte, N. C., 544,198. Filed Nov. 30, 1894.

Details of construction.

Electric Railway and Tramway, J. Claret, Lyons, and O. Wuilleumier, Clermont-Ferrand, France, 544,209. Filed July 25, 1893.

Automatic distributors are employed to supply the current to the motors.

Switches, Cut-Outs, etc.:—

Method of and Means for Extinguishing Electric Arcs, W. B. Potter, Schenectady, N. Y., 543,892. Filed Nov. 30, 1894.

Consists in restraining the path of the arc to a line of direction transverse to the lines of force from an arc-disrupting means tending to extinguish it.

Rheostat, W. O. Meissner, Chicago, Ill., 544,047. Filed Nov. 20, 1893.

Automatic Cut-Out for Electrical Converters, W. J. Greene, Cedar Rapids, Iowa, 544,094 Filed March 9, 1895

Controlling Switch for Electric Motors, W. J. Pohlman, Woodbrook, Md., 544,236. Filed June 4, 1895.

Telegraphs:—

System of Multiplex Telegraphy, T. B. Dixon, Henderson, Ky., 543,984, Filed Oct. 19, 1894

Operates with currents of different strengths and selecting relays.

Telephones:—

Telephone, J. S. Biggar, San Francisco, Cal., 543,813. Filed Nov. 16, 1894.

For description see page 160, this issue.

Telephone-Exchange System, C. E. Scribner, Chicago, Ill., 543,901. Filed Nov. 12, 1894.

The various necessary signals from the sub-station to the central station are transmitted automatically in the use of the sub-station telephone.

Apparatus for Telephone Switchboards, C. E. Scribner, Chicago, Ill., 543,-902. Filed Dec. 8, 1894.

Object is to perform the connection and disconnection of the telephone with the plug-circuit automatically at suitable stages in the process of making connection between lines.

OBITUARY.

BENJAMIN KINKHEAD, formerly manager of the Postal Telegraph Co. at Cincinnati died a few days ago at Albuquerque, N. M., whither he had gone for the improvement of his health.

THE EDISON ELECTRIC ILLUMINATING COMPANY, of Altoona, Pa., E. B. Greene, Supt., has awarded the following contracts for the new power house and apparatus: Building, to W. V. Hughes, of Altoona, Pa.; engines to The Ball & Wood Company, of New York; boilers to the Edge Moor Iron Co., of Wilmington, Delaware; dynamos to Pennsylvania General Electric Company, Philadelphia; self-supporting stack to the Edge Moor Iron Co., of Wilmington, Delaware.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE CUTTER E. & M. CO.'S AUTOMATIC MAGNETIC CIRCUIT BREAKERS.

An automatic magnetic circuit breaker may be considered a safety valve for electric circuits. Prior to the development of a line of automatic magnetic circuit breakers, by the Cutter Elec-

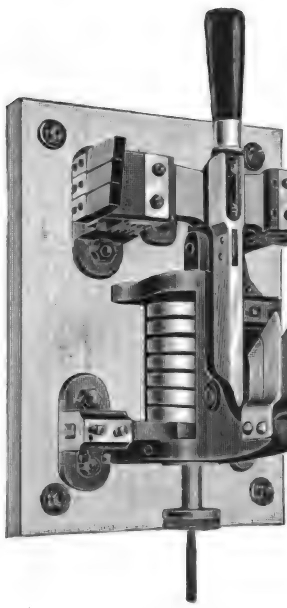

Fig. 1.

trical & Manufacturing Co., Mr. W. E. Harrington, the electrical engineer of the company, made a thorough study of the subject. The results of this study and investigation led to the design of an automatic magnetic circuit breaker which involves original features, and which has met every condition in practice imposed upon it.

Fig. 1 illustrates the standard form, which is adapted for 110–

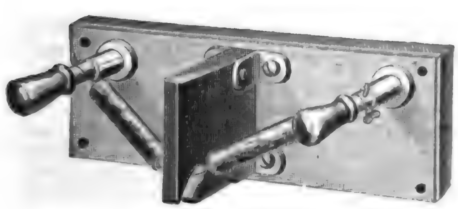

Fig. 2.

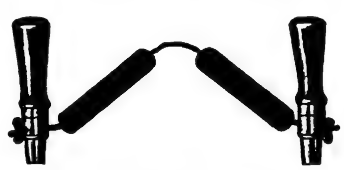

Fig. 4.

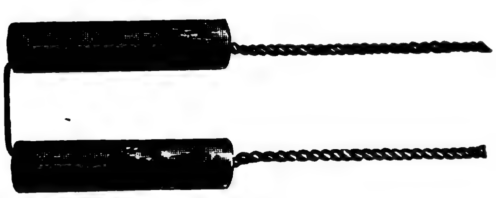

Fig. 3.

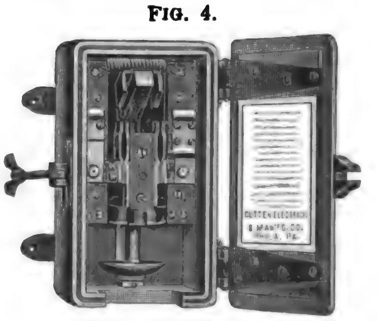

Fig. 6.

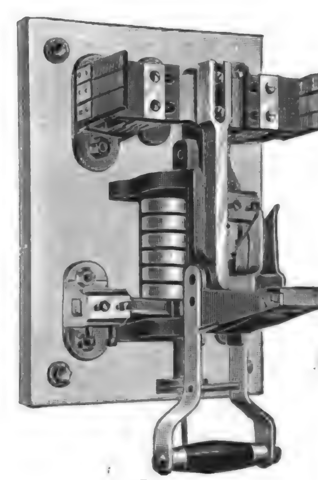

Fig. 5.

New Harrington Automatic Magnetic Circuit Breakers.

220 volt work. When employed on 500 volt circuits a fuse or shunt block, Fig. 2 is used; the protected terminal fuse, Fig. 3 is connected so as to be in shunt to the main switch break of the circuit breaker, thus preventing the destructive arcing which would otherwise occur at the switch. To facilitate quick resetting of the circuit breaker, extra plugs shown in Fig. 4 are furnished with each shunt block. The protected terminal fuses are the development of years of experimentation, and by their construction the arcing and burning of the terminals so common in the use of ordinary fuses in high voltage work is entirely eliminated.

The salient features of the Harrington automatic circuit breakers are: 1. Freedom from arcing at switch-jaws, thus preventing injury to the contact surfaces. 2. Time element; that is, the time of opening the circuit becomes less and less as the conditions of the circuit protected approach nearer and nearer a short circuit. The device will open circuit in $\frac{1}{10}$th part of a second under the latter condition. 3. Positiveness in opening: That is, if the plunger moves at all, the blow struck is, under all conditions, such that the switch will open. 4. A natural relieving of the load from the generators through the medium of the arc established at the fuse, which is so constructed as to allow of a long arc. It is manifestly incorrect to try to stop the arcing attendant upon opening a circuit by a circuit breaker too suddenly, because if too quickly opened the induced electro-motive forces tend to disrupt insulation. 5. Constancy of adjustment, which is due to weights and fixed distances. 6. Safety: Every provision is adopted to insure protection, although having fuse protection; in event of failure of fuse, or forgetfulness on the part of the operator to replace the fuse, the circuit breaker is provided with carbon final break.

Fig. 5 represents a circuit breaker with a special swinging arm handle of such a construction as to permit the placing of the circuit breaker at the top of the switch board.

The Cutter Electrical & Manufacturing Co. have appreciated the desire of the Fire Underwriters and others, and have designed a full line of circuit breakers made up roughly for house service connections, mine installations and rough factory work. This line, while employing all features and refinement of adjustment of the finer switch board circuit breakers, is made up without any finish and mounted on plain slate slabs. This rough line is made in both single and double pole patterns, in order to do away entirely with the use of a knife blade switch and fuse blocks.

Fig. 6 illustrates an automatic magnetic circuit breaker designed for the protection of car motor circuits, constructed upon the same general lines entering into the design of the switch board type.

FIRE-PROOF INSULATION.

Messrs. Aylsworth & Jackson, of Orange, N. J., the manufacturers of incandescent lamp filaments and other carbon specialties, have lately been giving attention to insulating materials. As a result, they are about to put on the market an insulating substance which has the property of smothering fire when brought in contact with it. It is proposed to use the material in the covering of electric light wires, etc.; by its use the insulating qualities are improved and the fire-proof qualities added.

PACKARD LAMPS AND TRANSFORMERS IN CANADA.

The Packard Electric Co., Ltd., of St. Catharines, Ont., announce that their new factory, on one of the finest manufacturing sites in the Dominion, is now in full operation manufacturing lamps and transformers. The factory is equipped throughout with new and improved machinery.

In order to give the business personal attention, Mr. W. D. Packard has assumed the general managership of the company, with Mr. G. A. Powell as assistant, an assurance that all orders will receive careful attention.

"COMING RIGHT ALONG."

Mr. Frank H. Clark, general superintendent of the U. S. Electric Lighting Co., Washington, D. C., writes to inquire about Data Sheets and says: "If there is another, we would like to receive it as it is too good a thing to lose."

A 78-INCH JEWELL BELT.

ELECTRICAL work has called for large belting in the past, but what is said to be the largest belt in the world is that just furnished by the Jewell Belting Co., of Hartford, Conn., to the Washburn & Moen Mfg. Co. This belt is 118 feet long, 78 inches wide and four-ply, and weighs considerably more than a ton and a half. Our engraving, Fig. 1, shows the belt rolled up as it

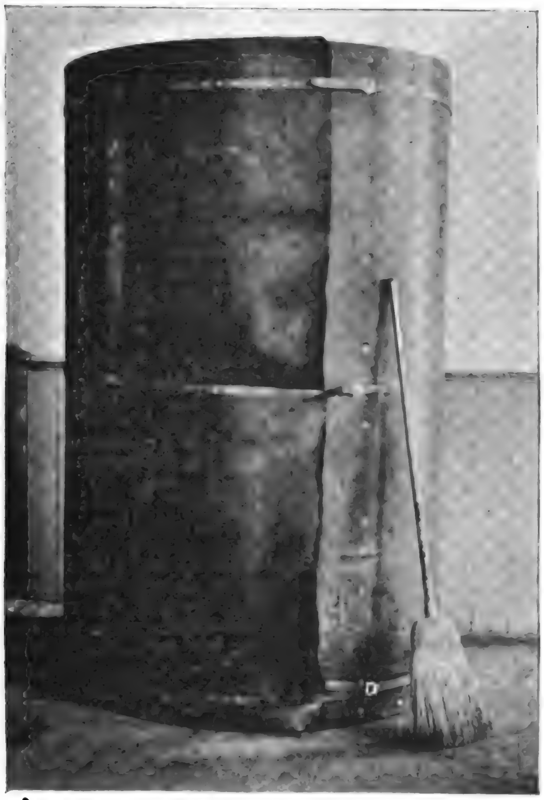

FIG. 1.—78 INCH JEWELL BELT.

appeared before shipment from the factory and Fig. 2 shows it in position at the works of the Washburn & Moen Mfg. Co. at Worcester, Mass., where the increased demand for electric wire has necessitated an increase in the power plant.

The belt will be called upon, when running its full load, to transmit 2,000 H. P. It will be used to run Mills Nos. 1, 3, 4, 7, 8,

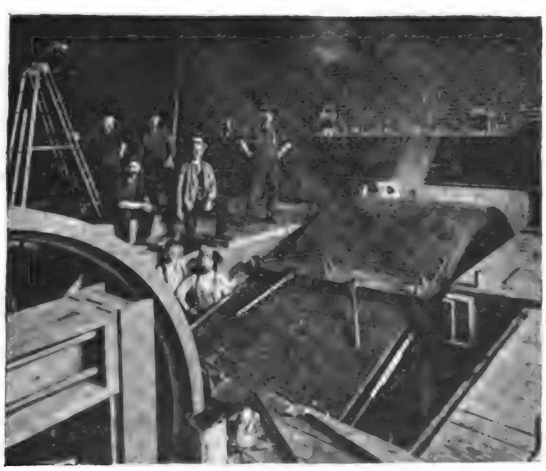

FIG. 2.—78-INCH JEWELL BELT IN POSITION.

12, 17, 18 and 19, comprising at least two-thirds of the power consumed in their Grove street works. This belt has now been running over a month, and running as true and steady as an ordinary narrow single belt.

It is worth noting that on the same day on which the Jewell Co. received the order for this 78-inch belt they also received an order for five 62-inch three-ply belts for the Cincinnati Street Railway Co. It is safe to say that the combination of the Cincinnati belts and this 78-inch belt is the largest number of very large belts ever ordered from one company in a single day.

THE BRYANT MARINE SWITCH.

THE recent successful trip of the U. S. Cruiser "Columbia," placing on record an average of 18.41 knots or over 21.5 statute miles per hour crossing the Atlantic, makes us look with pride upon our American ship builders. This ship and also the St. Louis and the St. Paul were built by Cramp & Sons, who now stand in the forefront of builders of large ocean vessels.

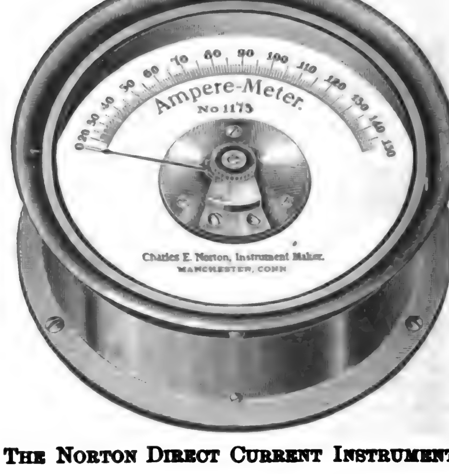
In the electrical equipment as well as in all other parts it is the aim of this company to place the best that can be had in its finished work, and many things have been designed especially for them. In the latter two vessels the switches were furnished by the

THE BRYANT MARINE SWITCH.

Bryant Electric Company, of Bridgeport, Conn., and consisted of their well-known black china switches and a special marine switch which we illustrate. This switch consists of a metal box containing a ten-ampere single pole Paiste switch mounted on a porcelain base; the holes for the wires in the metal box are protected by porcelain bushings and the box is covered with a metal top, the handle projecting. Grier Brothers, the western managers of the Bryant Electric Co., Monadnock Building, Chicago, carry these switches in stock.

THE NORTON DIRECT CURRENT INSTRUMENTS FOR SWITCHBOARD USE.

We illustrate in the accompanying engraving the type of new instruments manufactured by Charles E. Norton, of Manchester, Conn. The instruments are made so that the scale divisions are widest where they are used most, in order to give the greatest deflection for a given change of current. The voltmeter and



THE NORTON DIRECT CURRENT INSTRUMENT.

ammeter are both designed so that they can be left in circuit continuously without overheating and introducing a heating error. Special care has been taken to secure accuracy, as well as symmetry of design.

WORK OF THE SYRACUSE STORAGE BATTERY CO.

The Syracuse Storage Battery Co., Herald Building, Syracuse, N. Y., have asked us to correct a notice which appeared in our issue of July 31, which credits the installation at Dey Bros. & Co. to the Electric Engineering & Supply Co., of that city. The installation was done by their electrician, Mr. A. F. Clark, assisted by William Lalor. The Electric Engineering and Supply Company built the switch board only.

The business of the Company is improving, and they number with their recent contracts the following lighting plants: Onondaga Dynamo Co., Syracuse, N. Y.; Edwin Millner, Moosup, Conn.; Crown Mills, Marcellus, N. Y., 2 plants; Charles Fletcher, Providence, R. I., for the yacht "Seneca"; the Kansas State Normal School, Emporia, Kansas.

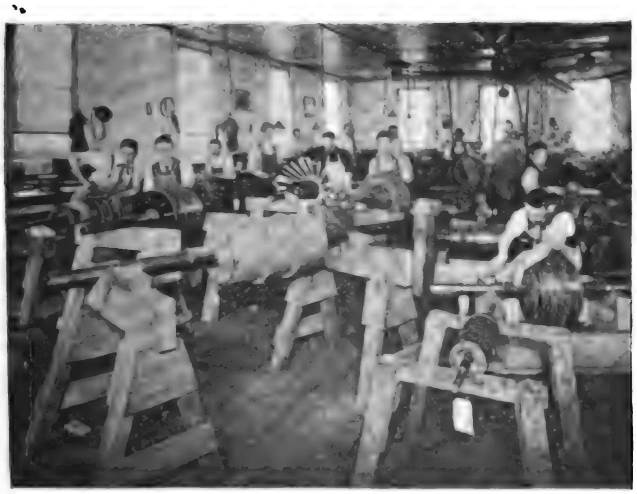
The Company will have an exhibition at the State Fair in connection with the Onondaga Dynamo Co., and the Whitman & Barnes Automatic Oil Engine. This will be a combination of home enterprise, and will be a very interesting feature.

THE CHESLEY ELECTRIC CO.

W. S. Chesley.

THE electrical field is strikingly full of self-made men, and among those who, by dint of hard work, have reached a position of responsibility and respect is Mr. W. S. Chesley. Born in 1860 at Hannibal, Mo., he received a common school education and commenced his electrical career in 1876, working six months as a messenger for the Western Union Telegraph Co., for an opportunity to learn Morse. He left the service temporarily to accept a clerkship but subsequently obtained his first position as operator in 1878. A year later he was appointed Manager of the American Union Telegraph office at Hannibal, and on the consolidation of this Company with the Western Union in 1880 he was sent to Kansas City. He soon became an expert operator and after working in several large cities was appointed Chief Operator at Little Rock, Ark., in 1882. In 1884 he was appointed Manager of the office at Galveston, Tex., the largest relay office in that section and the terminus of the Mexican and South American Cables.

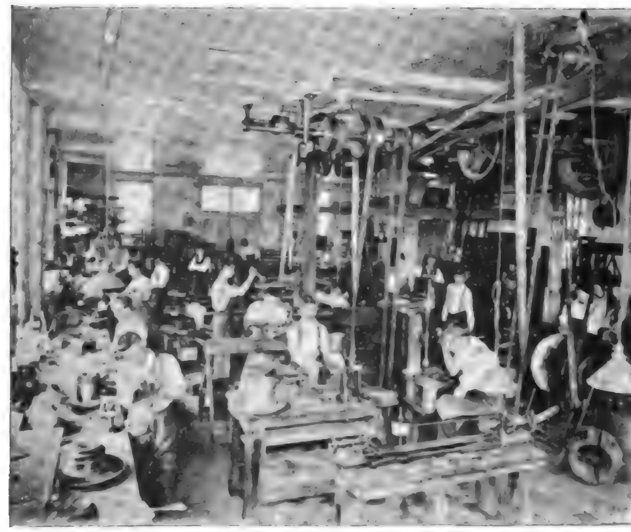
In 1888 Mr. Chesley came to New York to engage in electric



THE ARMATURE WINDING DEPARTMENT.

lighting but inexperience and poor health presented serious drawbacks. He worked about a year in the construction department of the United States and Westinghouse Companies and later acted as salesman for the Continental Dynamo Co., in which capacity he was quite successful. In 1890 he started in business for himself as electrical engineer and broker making a specialty of second-hand machines, and in 1892 opened a repair shop in Jersey City, subsequently purchasing the property in Hoboken where he is now located, two interior views of which are shown on this page.

The factory building, 75 x 85 ft., is located at Nos. 601 to 605 Newark st., Hoboken, N. J., opposite New York City. They have 28 men employed and make a specialty of repair work, more particularly alternating current apparatus, having excellent facil-



THE MACHINE WORK DEPARTMENT.

ities for handling large generators. A unique feature of this concern is the fact that they keep open day and night.

The Chesley Electric Co., in addition to repair work and second-hand apparatus has also commenced the manufacture of a bipolar dynamo with wrought iron fields which they will build up to 50 H. P.

RECENT SALES OF EDDY APPARATUS.

MESSRS. H. B. COHO & Co., of New York, agents for the Eddy Electric Mfg. Co., report the following sales of Eddy apparatus: Four 100 K. W. belt driven generators to Oscar Hammerstein for the Olympia Opera House, New York; one 60 K. W. generator to the Asbury Park Electric Ry. Co.; one 80 K. W. generator to John E. Beggs, Paterson, N. J; one 30 K. W. direct connected generator to Oscar Wiederhold; one 30 K. W. belt driven generator to the Lancaster Caramel Company, Lancaster, Pa.; storage battery plant to the New England Hotel, New York; one 20 H. P. motor to Freedman, Rennard & Company; one 10 H. P. motor to the New York Electrical Equipment Co.; one 3 H. P. motor to the Backus Water Motor Company.

BIDS WANTED.

W. B. Dunnegan, Cashier of the Polk County Bank, Bolivar, Mo., is receiving bids for an electric light plant which the city expects to put in right away.

USING A STEAM LOCOMOTIVE FOR AN ELECTRIC LIGHTING PLANT.

A SPECIAL dispatch from Westfield, N. Y., to the *Dunkirk Grapebelt* says:—It has been quite a serious question how to keep the plant running while the change of boilers was being made, but the *Scientific American* and Supt. J. G. Finlay have solved it. A Nickel Plate locomotive will be run onto the switch, back of the electric lighting building, and connections will be made with the boiler of the locomotive. This will furnish the necessary power to run the incandescent lights and no difficulty will be experienced by those who depend upon the plant for lights in their homes or places of business.

It will probably take about ten days to set the boiler, and it will cost $7.50 each night for the locomotive and engineer.

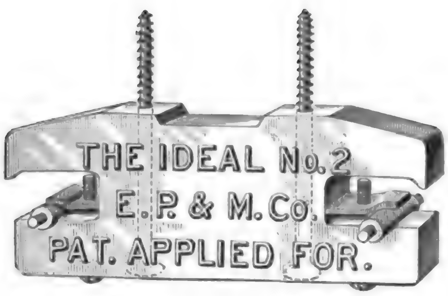
THE GULF TELEPHONE, TELEGRAPH AND ELECTRICAL CO.

This company has just been organized at Mobile, Ala., with Mr. Paul Minnis as general manager. The company will undertake contracts for all kinds of electrical construction, including telephone and telegraph lines, the furnishing of complete specifications and estimates on power and lighting plants; they will also deal in electrical supplies. The company is backed by solid business men and with the energetic Mr. Minnis at the helm will without doubt make a good showing.

THE "IDEAL" ONE PIECE CLEAT.

Our illustration represents a new one-piece porcelain cleat recently put upon the market by the Electric Porcelain and Manufacturing Co., of 309-315 Monmouth St., Trenton, N. J.

This cleat is made of white, thoroughly vitrified and tough porcelain, and besides the advantage of being self contained in one piece has a number of other characteristic features. Thus owing to the two bearings with which it is provided it will not break when secured to the ceiling. In fixing the cleat, flat head



The "Ideal" One Piece Cleat.

wood screws are used, which are countersunk in the porcelain, being fully one-quarter inch from the clamp screw. The clamp is made of stamped brass having a longitudinal corrugation which keeps the wire tight, held in position by a round-headed machine screw. The overhanging lip also protects the wire from moisture. These cleats are made in two sizes, the smaller taking wire from No. 14 to No. 6, and the larger from No. 6 to No. 0. The company have a well equipped shop for making dies and employ only skilled workmen.

SAVED BY THE FENDER.

The Philadelphia Traction Company issued on Aug. 1 a list of 16 people whose lives, it is stated, had been saved on its lines by means of the "Standard" fenders it is using.

INSPECTING ELECTRIC METERS IN CANADA.

An Order-in-Council has been passed defining the regulations for the inspection of electric meters in Canada. It provides that all electric light supply meters shall be presented for verification one-third before the 1st of December next, one third before the 1st of March, 1896, and one-third by the 1st of July, 1896. The order further provides that for every unverified meter found in use after the first of July next, the owner, that is the company, not the consumer, shall incur the penalty of $25. The fine for failure to neglect to afford the department ample testing facilities is $50.

THE GEDNEY CHANNEL LIGHTING.

With regard to our recent article on the extension of the electric lighting of Gedney's Channel, we are glad to be able to add that the originator of the system of thus lighting the channel was Capt. Winfield S. Schley, U. S. N., and that the officer who carried the work to completion was Capt. N. S. Snow, U. S. N.

NEW YORK EDISON CO.'S EARNINGS FOR JULY.

We give below the earnings of the Edison Electric Illuminating Co., for July, the statement including the Manhattan and Harlem Co.'s:

	1895.	1894.	Increase.
Gross, July..................	$ 124,181.24	$108,014.40	$16,166.84
Net, "	56,344 32	45,428 21	10,916.11
Gross, 7 months..................	$1,071,626 30	933,352.83	138,273 47

LOSSES OF STEAM TRAVEL AROUND PITTSBURGH.

The McKeesport, Pa. *Times* says:—The number of people of this city who daily travel over the Second avenue line to Pittsburg, led the *Times* to make some inquiries. The *Times* was informed by a Baltimore & Ohio railroad man that the company's general travel to Pittsburg from McKeesport had greatly fallen off, probably to the amount of more than a thousand tickets in a month, but that the regular monthly tickets had not fallen off. In fact, last month showed the sale of 70 monthly tickets from McKeesport, the largest number ever sold from here in one month. The monthly tickets are given at such a low figure that the company may retain that class of patrons. But it is a fact that some of the monthly patrons of the Baltimore and Ohio railroad are endeavoring to get the Second Avenue company to offer them a monthly ticket for the same price as charged by the Baltimore and Ohio, or less. In that case the Baltimore & Ohio might lose a large proportion of its monthly patrons between Pittsburg and McKeesport. On the Pittsburg, McKeesport and Youghiogheny railroad, the Pittsburg travel from McKeesport, which was light, has not been reduced very much, but the Homestead travel has fallen off very considerably.

NEW YORK NOTES.

The Abendroth & Root Manufacturing Company, 28 Cliff St., New York City, manufacturers of the Improved Root Water Tube Boiler, have been awarded the 626 h. p. boiler contract from the Union Car Company of Buffalo, N. Y., and a 500 h. p. contract from the Reading Steam Heat & Power Company of Reading, Pa. They are also erecting in New York City boilers of 300 h. p. in the College of Physicians and Surgeons; two boilers in the Baptist Home; one boiler in the Parmly Building, and two boilers for the Sing Sing Electric Lighting Company.

Mr. J. Day Flack, M. E., who has so long been connected with the engineering department of the Edison and General Electric Companies, has opened an office at 26 Cortlandt St., New York City, where he will undertake general consulting, designing and supervising work, both electrical and mechanical. Mr. Flack will pay particular attention to the supervision of electrical work for architects, the design and construction of plants for electric light and power, electric traction, electric transmission of power, steam plants and special machinery and processes for the manufacture of incandescent lamps. He is also prepared to undertake commercial tests of engines, boilers and apparatus for electric lighting or power. Mr. Flack is a graduate of the Stevens Institute of Technology and a member of the American Institute of Electrical Engineers.

WESTERN NOTES.

Mr. Wm. H. Leitch, secretary of the Abendroth & Root Mfg. Co., of New York, was a Chicago visitor last week.

The Electric Appliance Company have taken the exclusive selling agency of the United States for that celebrated commutator preserver "Gales Compound." The price has been somewhat reduced and an increased sale is anticipated.

The Fontaine Crossing and Electrical Co., of Detroit have recently sold through their Northwestern Agent Mr. F. B. Thompson, of the Rookery, Chicago, a 100 k. w. dynamo to the American Gas Engine Electric Co. This machine which it is intended to have belted to one of the new imported 150 h. p. tandem gas engines of the latter company, will be located at their plant at Lake and Clark streets, Chicago.

The Triumph Electric Co. of Cincinnati have opened an office with Turner Bros., No. 25 Marietta street, Atlanta, Ga., with Mr. E. F. Seixas, formerly with J. Holt Gates, of Chicago, in charge. Mr. Seixas will draw up specifications for complete plants of all descriptions and will install and take charge of the exhibit of the above company at the Cotton States Exposition, and will be pleased at all times to explain their apparatus to interested parties.

The Borden & Selleck Co., 48-50 Lake street, Chicago, have lately closed contracts for Harrison conveying and elevator machinery as follows: The coal storage plant and for conveying coal from cars to the two batteries of boilers for the Toronto Street R. R. Co., Toronto, Ont., the contract including a large crusher for crushing bituminous coal; coal handling plant for J. F. Clancy & Co., Racine, Wis.; coal conveyors and elevators for C. P. Wilder & Co., South Chicago, Ill.; coal conveyors and elevators for E. L. Hedstrom & Co., at their new Thirty First Street Yard, and coal conveyors for handling coal to boilers, including storage tanks; also power crusher for the N. W. Electric Transit Co.'s North Chicago power house. They report business as improving and their factory is run to its full capacity.

NEW ENGLAND NOTES.

Massachusetts Figures show that while 4103 men were employed on the street cars in the State under the old horse system, the number is now 7451; and the number of passengers has risen from 100,746,786 to 220,464,099.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

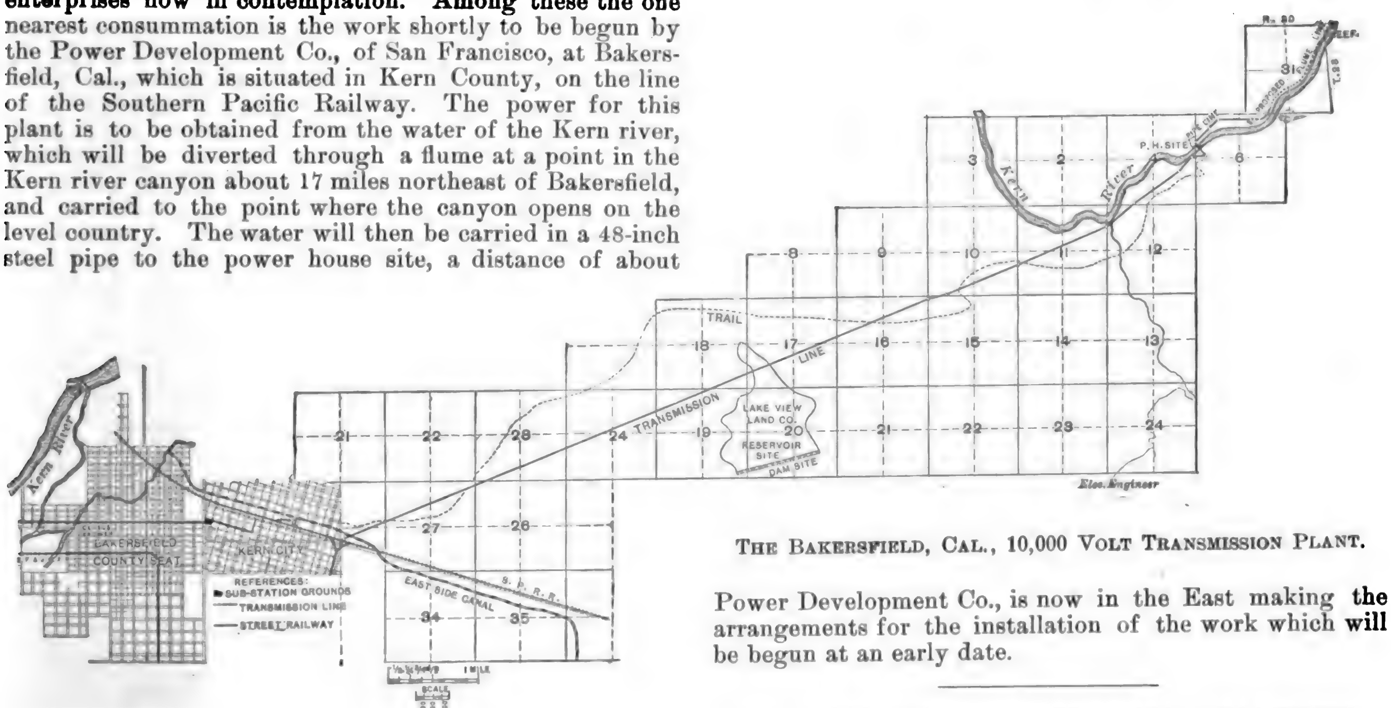
THE

Electrical Engineer.

Vol. XX. AUGUST 21, 1895. No. 381.

THE BAKERSFIELD, CAL., LONG DISTANCE POWER TRANSMISSION.

THE high cost of fuel prevailing in most parts of California, has turned enterprising capitalists to the utilization of the numerous water-powers which abound among its mountains. Our readers will recall the Pomona plant and the recent inauguration of the Folsom-Sacramento transmission plant, which may be said to be the pioneers of many similar enterprises now in contemplation. Among these the one nearest consummation is the work shortly to be begun by the Power Development Co., of San Francisco, at Bakersfield, Cal., which is situated in Kern County, on the line of the Southern Pacific Railway. The power for this plant is to be obtained from the water of the Kern river, which will be diverted through a flume at a point in the Kern river canyon about 17 miles northeast of Bakersfield, and carried to the point where the canyon opens on the level country. The water will then be carried in a 48-inch steel pipe to the power house site, a distance of about 4,200 feet, at which place the head will be 240 feet. The power house site is about 15 miles by wagon road northeast of Bakersfield. These locations are shown on the accompanying map.



THE BAKERSFIELD, CAL., 10,000 VOLT TRANSMISSION PLANT.

There will be installed in the power house generators of not less than 1,200 H. P. capacity to be direct driven from water wheels (provisions being made for increasing the capacity at a later date). The power house is to be connected with a sub-station in Bakersfield by a transmission line of 1,500 H. P. capacity, at a loss in line of not more than 10 per cent.

The length of the transmission line from the power house site to the town limits is about 11½ miles and from the town limits to the sub-station about 1.8 miles; the line will be run in two independent circuits. Besides the power conductors, there will be strung on the poles a No. 12 copper, twin twisted telephone cable.

At the sub-station in Bakersfield there will be installed step-down transformers which will reduce the line potential of 10,000 volts to 2,000. These transformers will have a capacity for supplying 1,000 16 C. P. 60 watt incandescent lamps and 180—2,000 C. P. alternating current arc lamps. In addition there will be installed a constant current arc machine with a capacity of 100—2,000 C. P. lamps which will be driven by a synchronous alternating motor, and two rotary transformers, of a combined capacity of 100 H. P. at 550 volts pressure direct current.

Besides the distribution of light and power the company will also operate an electric railway between Bakersfield and the adjoining town of Kern. The initial equipment will consist of four motor cars and four trailers.

Mr. Carroll N. Beal, secretary and treasurer of the Power Development Co., is now in the East making the arrangements for the installation of the work which will be begun at an early date.

THE SABIN-HAMPTON "EXPRESS" TELEPHONE SWITCHBOARD SYSTEM.

A PECULIAR feature of the telephone business has been that the cost per subscriber of central office equipment is much greater in large than in small exchanges. The cause of this remarkable condition, so different from ordinary experience in business where magnitude of operation goes hand in hand with relatively decreased working expenses, is to be found in the employment of the "multiple" system of switchboards. That is a point long since thoroughly appreciated, but one from which there has seemed little prospect of relief. The multiple board, by reason of its greater efficiency over other and earlier attempts to cope with the rapidly-increasing tide of telephone business, was adopted in spite of its cost. It was a case of efficiency against economy, and efficiency won.

Since the introduction of the multiple system, however, telephone switchboard development has been distressingly slow; the aim of inventors evidently being mostly directed on minor points on old lines rather than on original work in new directions. It is not the intention here to assign the reasons for this case of arrested development. It is sufficient to point to the facts as they are, and indicate by a brief statement the underlying principle of the multiple board

with its shortcomings in order to better understand the advantages possessed by a new departure in this field.

The essential principle of the multiple system is that all subscribers' circuits are accessible to any operator in an exchange. That is accomplished by furnishing each subscriber's circuit with numerous springjacks, one of which is within reaching distance of any operator, regardless of her working position. This repetition of working parts produces great complexity, which is much increased by the necessity of providing a busy test at every jack, so that while a line is in use it may be free from interruption.

It is unnecessary to describe the means adopted to obtain this, further than to say that on every jack there is a point which is automatically connected with a battery at the proper time. By touching the point with a plug an operator can, by the presence or absence of a click in her receiver, determine whether a line is busy or free. In spite of this precaution, it is a fact that lines are frequently interrupted, to the great annoyance of all concerned. The opportunity always open to careless operators to make mistakes of this sort is undoubtedly the cause of much popular dissatisfaction with the telephone service furnished in large cities.

To obviate some of these defects of the multiple board, Messrs. Sabin and Hampton, of San Francisco, have designed a system known as the "express" system of switching, on radically different lines.

It may be well, first of all, to state here the most prominent points of difference between the two systems.

In the multiple board there are many working parts in each circuit, involving the use of a "busy" signal. In the Sabin-Hampton board there is no repetition of working parts and consequently no need for a busy test. In the multiple type of board everything is designed to permit the operator who answers a call to complete a connection unaided; while in the system under consideration the work is divided among three operators, each having a special function to perform.

In the accompanying diagram which illustrates the "Express" system, a calling subscriber is represented in electrical communication through the exchange with another subscriber; but in order to better understand the manner in which this is accomplished let it be supposed that the calling subscriber has his receiver on the gravity switch; that plug 1 is not in jack 1; and that the springs of the jack rest on the inner contacts leading to drop 1, and subscriber's signal battery, which is the normal condition.

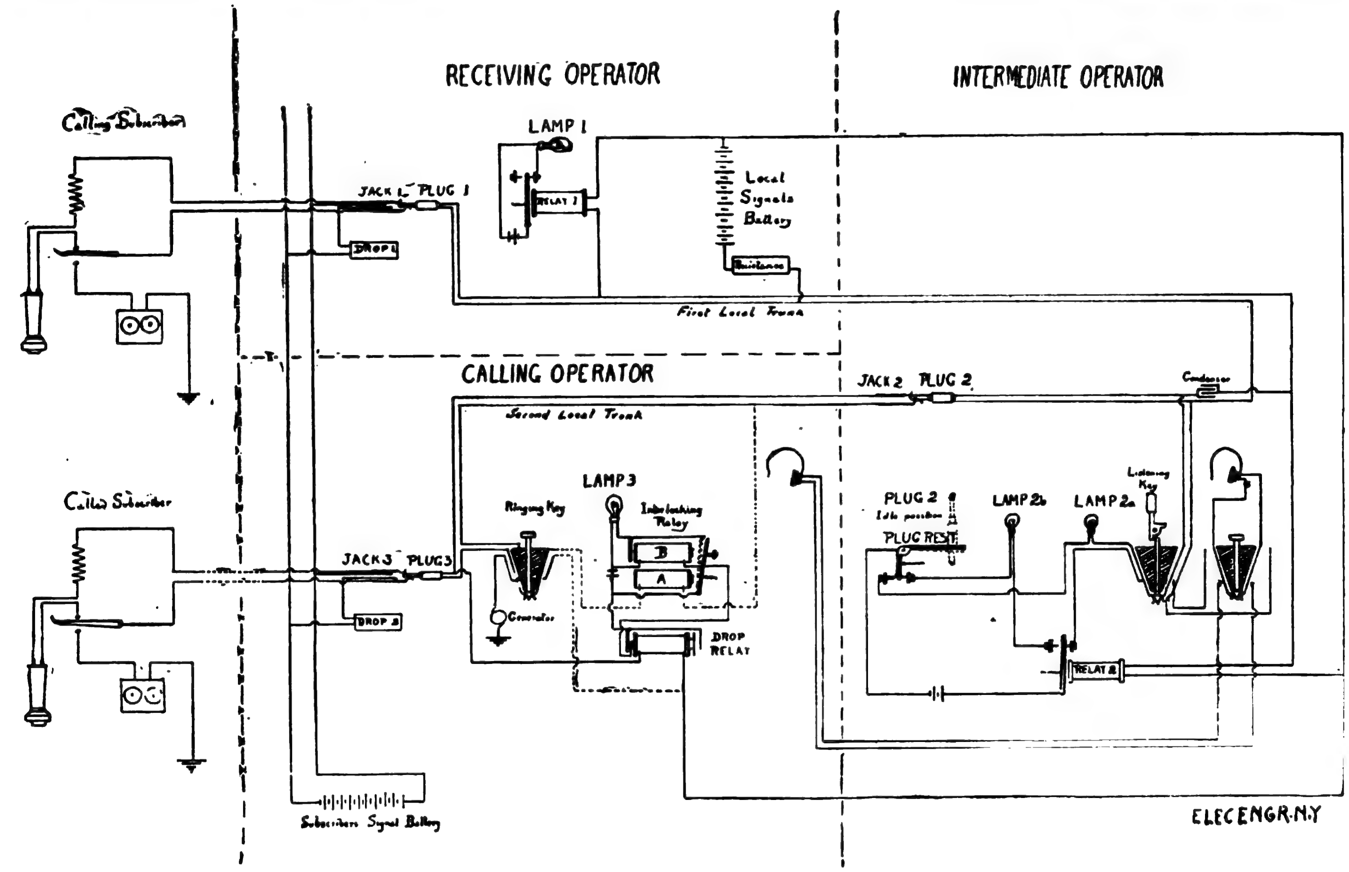
In order to call central under those circumstances, all that it is necessary for the calling subscriber to do is that he take his receiver off the hook, thereby closing his circuit through his receiver and secondary, and throwing drop 1 by the current from the subscriber's signal battery. It should be noted that no magneto is used by the subscriber.

The "receiving" operator, noticing the call, inserts plug 1 into jack 1, which breaks the drop circuit, restores the drop, and extends the subscriber's line through the first local trunk to the "intermediate" operator. Further than that she has no concern with the call other than to clear the connection when the conversation is finished.

The intermediate operator is notified that some one is calling on the local trunk by the lighting of lamp 2*a*. The working of the lamp will be described presently.

Pulling down the listening key, the intermediate operator puts herself in communication with the calling subscriber and, finding out whom he wants, presses her local calling circuit key, of which she has several, and requests the calling operator, who has the desired subscriber on her case, to put him on one of the second local trunks. The calling operator states what second local trunk is to be used, and the intermediate operator puts plug 2 into jack 2, which extends the line of the calling subscriber to the case of the calling operator.

The calling operator then completes the connection by inserting plug 3 into the jack of the called subscriber.



The Sabin and Hampton "Express" Telephone Switchboard System.

The calling operator next presses her ringing key and sends out current from the exchange ringing generator through one side of the subscriber's line to the gravity switch, supposed to be resting on its under contact, to the subscriber's call bell and thence to ground. The called subscriber by taking his receiver off the gravity switch is then in communication with the subscriber calling him.

It now remains to describe the manner in which the operators are notified of the beginning and end of a connection.

That is done by means of the lamps, 1, 2 *a*, 2 *b*, 3, and the shutter of the drop relay. So long as the calling subscriber's receiver is off the gravity switch and plug 1 is in jack 1, relays 1 and 2 are energized by the local signal battery, as they form bridges across the circuit. Lamp 1, therefore, is lighted during the entire conversation. Until the intermediate operator pulls down her listening key, lamp 2 *a* is lighted and will relight if she should raise it without lifting plug 2 from its idle position. Lamp 2 *b* lights when the calling subscriber hangs up his receiver as relay 2 is then demagnetized. Lamp 2 *b* is equivalent to a ring-off drop.

The signals of the calling operator are controlled by the called subscriber. They would be controlled in the same way as those of the receiving and intermediate operators were it not for the condenser in one side of the first local trunk. On pressing the ringing key, magnet A of the interlocking relay attracts its armature and completes a local circuit through lamp 3, which remains lighted till the called subscriber answers.

When the drop relay acts, as the result of an answer from the called subscriber, the magnet B of the interlocking relay releases the armature of A, and the lamp goes out.

The calling operator is notified of the close of the conversation by the fall of the shutter of the drop relay.

It will be apparent from the above description that every part of the connection has its proper signal. Being automatic, there is no necessity for the operators wasting time in supervising connections, as is invariably the case where the ring-off signals are dependent on the thoughtfulness of the public.

For the sake of simplicity it has been represented that there are receiving and calling operators. As a matter of fact the same operators do both kinds of work. Receiving calls simply consists in turning over all calls to the intermediate operators for distribution amongst the calling operators. It can be done with no appreciable delay to calling business.

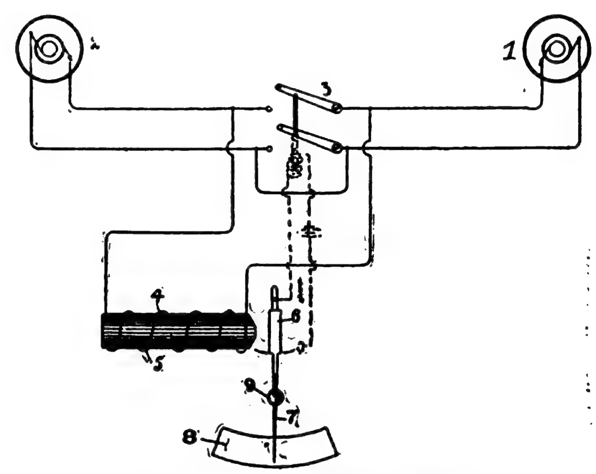
The "Express" system has been introduced into the San Francisco telephone exchange, where it has given excellent satisfaction.

THE MERSHON SYNCHRONISM INDICATOR.

In order to connect alternating machines in parallel to the same circuit they must be at the same phase, or in synchronism, and in order to determine this point various devices have been employed. Thus in some cases an acoustic indicator is used, while in others an incandescent lamp placed across the terminals of the machines to be connected is observed, and when at its greatest brilliancy the switch is thrown. The point of greatest brilliancy in an incandescent lamp is somewhat difficult to determine except by experience, and with the object of supplying a device which can be read off with accuracy by the ordinary station attendant, Mr. Ralph D. Mershon, of the Westinghouse Company, has devised the arrangement shown in the accompanying engraving. This indicator has the advantage also of being equally well adapted for alternating circuits of high and low frequency; the acoustic indicator being unavailable for frequencies below a certain limit.

The indicator consists of a coil 4 connected to the machines as shown and acting upon an armature which carries a pointer passing over a scale. The armature may be either of iron or consist of a closed coil or a disc of non-magnetic material; in the latter case being acted on inductively. Assuming the coil 4 to be so connected in circuit that the electromotive forces therein will be in opposition when the machines are in the proper relation for closing the switch 3, the armature 6 will, in the absence of such relation, be moved either toward or away from the coil 4 and its core 5, the direction of such movement being dependent upon whether the armature be of magnetizable or non-magnetizable metal. As the two machines approach the same speed and the electromotive forces come more nearly into opposition, the armature will tend to return to its original or zero position until the relation of the machines is such that they may properly be connected in circuit, when the armature and its pointer will be in approximately the position shown in Fig. 1.

If, on the other hand, coil 4 be so connected in circuit



MERSHON SYNCHRONISM INDICATOR.

that there shall be a coincidence of the electromotive forces therein when the machines are in the proper relation for connecting them in circuit, the operation of the device will be the reverse of that above described—that is to say, if the armature be of magnetizable material its extreme left-hand position will indicate the time for closing the switch, and if of non-magnetizable material its extreme right-hand position will give the proper indication, the vertical or zero position, indicating the absence of the desired relation of the two machines.

Mr. Mershon prefers to so connect the coil in circuit that there shall be an opposition of elecromotive forces therein at the proper time for throwing the switch and to employ a non-magnetic armature; but the other connection and variety of armature described are entirely practical and may be employed. It is obvious that the armature or its pointer may also serve, if desired, to close a circuit, which shall operate to effect the closing of the switch automatically.

THE DURABILITY OF ASPHALT CABLES.

Herr Görz, of St. Petersburg, writing in the *Elektrotechnische Zeitschrift* on the proposed German wiring rules, and proposing several amendments, refers to the question of the durability of insulated cables. He states that the whole underground network of the St. Petersburg Electric Supply Station consists of lead-covered asphalt Siemens-Halske cables, which have been working for the last six or seven years to entire satisfaction. The expenditure for repairs and renewals for the last year was only ½ per cent. of the total expenditure of 1,100,000 silver roubles on cables.

BUFFALO BILL'S PORTABLE ELECTRIC LIGHT PLANTS.

BY

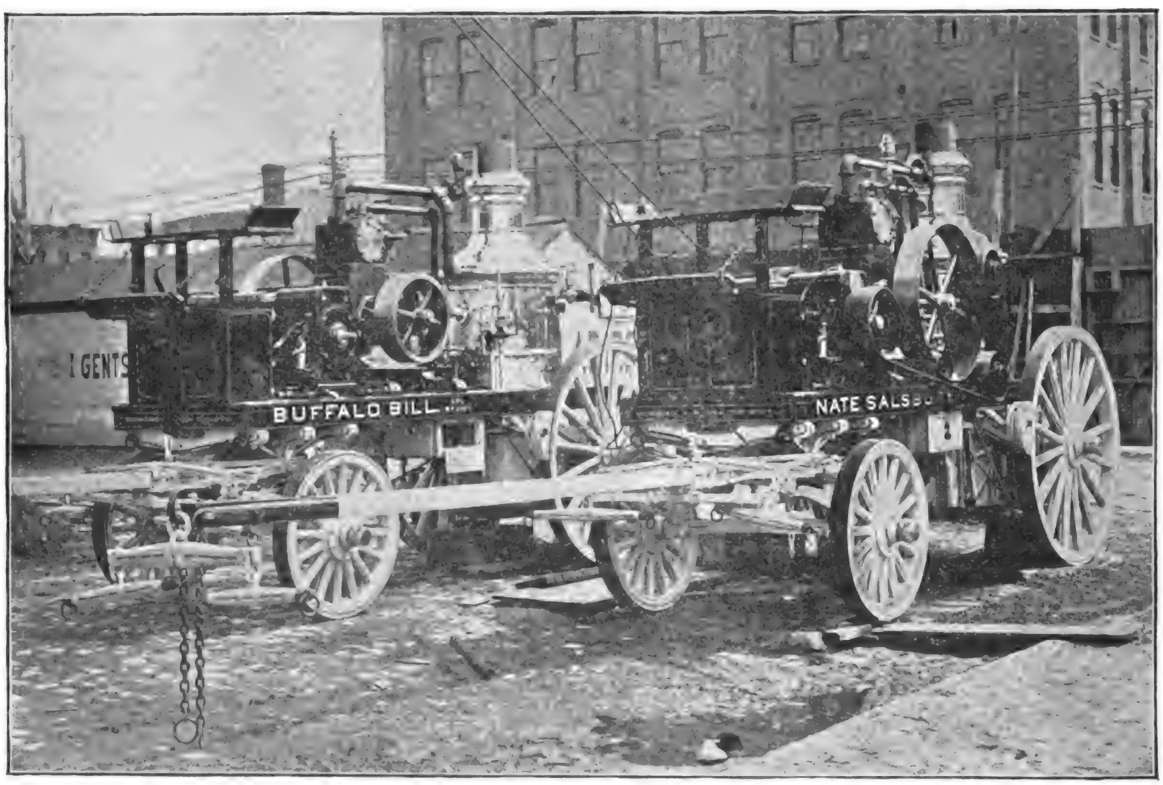
Frank B. Widmayer

VERY early this season the managers of the Buffalo Bill Wild West Show Co. considered the advisability of generating electricity for illuminating their show at night. This seems a very simple matter but under the circumstances it was a very difficult one—as the show has no permanent location this season but is on the road and is exhibiting in all the large cities and towns of this country; the number of nights of its stay in a town or city depending upon the size of the town and ranging from a one night's stand to two or three weeks. The Buffalo Bill Company consulted their electrical superintendent, Mr. M. B. Bailey, submitting the question whether it was not possible to build two portable electric light plants, alike in every respect and each being capable of running from 25 to 30 2000-candle power commercial arc lamps; each plant to operate an independent circuit; every alternate lamp to be connected to the circuits so that if anything went wrong with one plant they would be able to run half the lights and so light up the show that a fairly satisfactory performance could be given. It was further required that the plants be so constructed that upon reaching the ground where the show was to be exhibited that night, the complete plants, consisting of poles, line work, lamps, engines, boilers, dynamos, etc., could be set up and in running order inside of two hours; and after the show was over the complete plants could be taken down and loaded on their special cars ready to move to the next town inside of two hours. To these were added the further conditions that the various parts and the wagons should be light enough to be easily handled over ordinary roads by two or three horses.

In reply to these rather rough specifications Mr. Bailey said he was sure he could accomplish just what was wanted—and he was told to go ahead.

A great many plans were submitted to Mr. Bailey and the officers of the Wild West Co. by various electrical and mechanical engineering firms and, as there was very little precedent for such work, the plans and suggestions, as might have been expected, were widely apart. A decision was finally arrived at and the Ball Electric Light Co. of New York undertook to furnish the complete electrical plant, and all the novel and special electrical details connected therewith. The steam or power plant was built under Mr. Bailey's personal supervision.

The Ball Co. and Mr. Bailey working together finally designed and built the two novel plants shown in the accompanying engraving. These represent two duplex plants of 28 lights each. Each plant consists of a strong wagon. Supported on the wheels by heavy springs are two I-beams with cross bracing, forming the truck frame. Set below these beams on the rear axle is a burnished steel, copper tube Clapp & Jones fire engine boiler—of the type used by the fire departments of all our large cities. To this is piped a 25 horse-power automatic high-speed cut-off Case engine, which has proved to be a model of efficiency for this special duty, as it is light and very compact in proportion to its power, as is also the boiler. Connected to the boiler is an injector and a Worthington "Baby" feed pump. All the pump, dynamo, and engine fittings are nickel-plated and the iron work of the truck is heavily japanned and decorated, presenting a very attractive appearance.



BUFFALO BILL'S PORTABLE ELECTRIC LIGHT PLANTS.

In front of the boiler on the I-beams is mounted one automatic Ball 28-light, 10 ampere series arc dynamo,[1] which is insulated thoroughly from the base or truck, and it is provided with special self oiling dust proof bearings, etc. This machine is only 53 inches long, 24 inches high and 20 inches wide, and weighs about 1,500 pounds, being like the engine very, compact for its capacity.

1. This machine was fully illustrated and described in THE ELECTRICAL ENGINEER of March 20, 1895.

In front of the machine is the switchboard, which is located below the seat, and hence cannot be seen in the engraving. On this are mounted all the electrical instruments necessary for the proper operation of the plant, including a special portable ampere-meter reading up to 20 amperes—two Garton magnetic lightning arresters, a short-circuiting field switch, line terminals, etc.

The system of transmission of power between the engine and dynamo is by belting—an endless belt being used in connection with the L. P. & D. transmitter, which seems to be particularly adapted for a portable plant built as compactly as this one is. The weight of each plant complete, with its load of engine, boiler, dynamo, all fittings, coal and water, is about 5¼ tons, and this weight is properly supported by springs on special heavy wheels having 5 inch tires.

Both wagons appear in all street parades and they create quite a sensation among the electrical and mechanical community wherever seen. They can be easily handled by two horses, although six are generally used for street parade effect.

Both these plants have been in nightly operation for the last five months without a mishap or interruption of any kind. When it is considered that they have worked directly exposed to heavy thunder storms and in torrents of rain without the slightest protection from the weather, without the loss of an armature, the quality of the workmanship and insulation of the Ball dynamos needs no further pointing out.

It may be of interest to call attention to the reflecting arc globe used in connection with this plant, and designed by Mr. Bailey. This globe is a combination reflector and globe, and consists of two hemispheres; one of these is blackened on the outside and corrugated on the inside and silver plated, thus forming a very good reflector. The other half forming the front piece is of clear glass. These globes give an excellent diffusion of the light.

These plants will visit nearly all the important cities in the United States before the season closes and Mr. Bailey or Mr. B. C. Killin, the engineer-in-chief, will both be only too glad to explain and show them in all their details to any one interested. The writer sees no reason why such plants should not multiply rapidly as there appears to be a good field for them among contractors during night operations, and for military purposes.

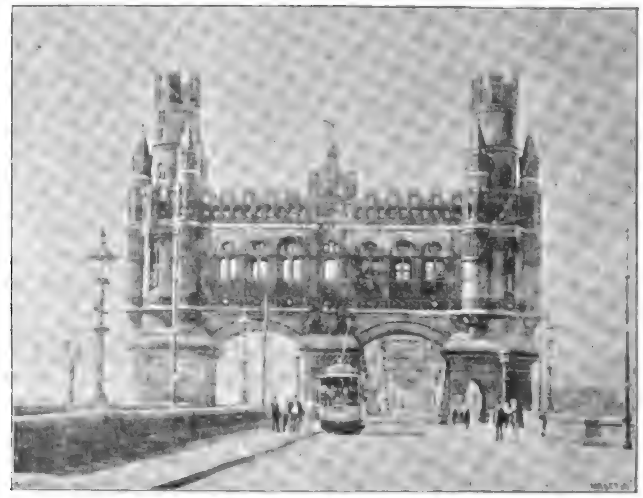
ROUNDABOUT NOTES IN ELECTRICAL EUROPE.—III

BY

HAMBURG.

The city of Hamburg is one of the oldest, most prosperous and beautiful of the many cities which abound in Germany. It has made enormous strides and its population is estimated at between 300,000 and 500,000, authorities differing. Its commerce is world-renowned and in its busy harbor ships of all nationalities are moored. Its merchants are in touch with almost every land and either export to, or import from everywhere. Evidences of prosperity are visible within her borders, and Hamburg boasts that no beggars infest her streets. Money is not so closely scanned here as it is farther South, and it is spent freely. When Emperor William passed through here to open the North Sea Canal, he found the generous residents had built a beautiful island in the centre of the lake, on piles, covered them with wire and stucco work, and erected a pavillion for royalty to drink coffee in and look around. This island was called the King's Island, cost $40,000, and was demolished after the Kaiser passed on. It was illuminated by incandescent lamps and search lights furnished by the electrical engineering establishment of Schuckert & Co., of Nuremburg.

Naturally people who go in for luxuries of this sort are likely to be good patrons of an electric road, and Hamburg has a system of which it may justly be proud. It



Side Pole Construction, Hamburg Electric Railway.

resembles an ideal American overhead road, more, perhaps, than any we have seen abroad. The road has about 50 miles of track, and extensions of some 30 miles are in course of construction; 160 cars are in service and in a few weeks 40 additional will be delivered. In time it is expected that there will be at least 300 in all.

The entire equipment was furnished and all construction was done by the well-known Union Elektricitäts-Gesellschaft of Berlin, of which Mr. Louis J. Magee, formerly in the United States, is managing director. Their well-known type of motor is used. It works beautifully and runs silently and without heating. The Messrs. Schuckert & Co. are expecting to lay about 6 miles of electric road on which they will operate their own motors, but this line is quite separate from the main Hamburg

Double Bracket Construction, Hamburg Electric Railway.

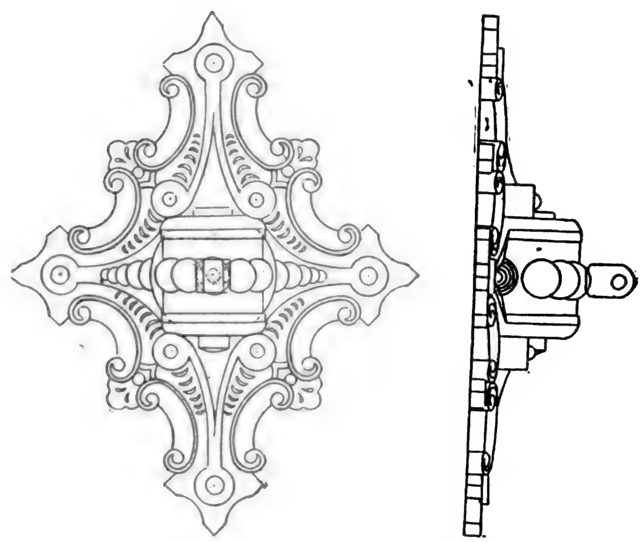
company. The daily receipts of the latter now average about $4,000, and on Sundays and holidays this increases to as high as $5,700.

Before the Company can accept a car or operate it, the Inspector of Police must approve of the car and sanction its use. The inspection is rigid and it is apparent

that the difficulty of making innovations, or introducing unknown types of apparatus, is great. Even if the railroad company wants an article, it can not put it in use without official consent.

The rails are supplied by the well-known Phœnix Co., whose works are located near Cologne. The trucks were built by the Remscheider Steel and Industrial Works. The street railway company builds its own cars in a very completely furnished plant of its own in the city. One hundred and twenty men are employed, but in addition to making repairs, these men only turn out 4 cars per week. The work is heavy and likely to be durable. A private car in process of finishing would do credit to any American car builder.

Some fine overhead work was done here on the bridges and in a square where no poles were allowed. By a re-inforcing wire arrangement the line is carried a long distance without any support from poles. A very important thing in the construction work is the great extent to which rosettes are used. These rosettes, as the accompanying illustration shows, are highly ornamental and very useful, too. Over 4,000 are in use and of course they save just that many poles. The streets are not so obstructed when the rosettes are used and they cost less than one-half the price of poles. They are properly insulated and are fastened into the masonry. Not only are they found on residences, warehouses and other buildings, but on the Kathrina and other churches, as well, and they certainly do not mar the walls. When the road was being built, the church authorities were given the option of having either poles or rosettes, and they wisely preferred the rosettes overhead, to the poles on the pavement in front of the sacred edifices.



Rosette for Trolley Suspension, Hamburg, Germany.

The motormen make but $21 to $24 per month and are furnished one uniform per year gratis by the Company. The conductors are paid less, but tips are given them by passengers, so they make more than their wages in tips. The cars here are heated by bricks which, when warm, are shoved into the place provided under the seats, much as accumulators were arranged in the old Julien cars on 4th avenue, New York. Hamburg uses German trucks but Bremen near-by uses the well-known Brill trucks. There is no provision whatever for ventilation. The windows of all cars are screwed fast and cannot be raised or lowered. If fresh air is demanded, the front door is opened and it comes in by wholesale. No modern sand box is used, but when sand is needed it is shoveled from a box; the car is stopped and sand distributed.

The fender arrangement on the Hamburg cars is very bad and gives no protection whatever. It would really suck a victim into the space under the motors. Its edges are made of ship's rope.

The first car began running on March 5, 1894, and it is very remarkable to notice how finely equipped the system is and how admirably it taps the important centres.

Electricity is about to displace steam on the Wandbek route. This part will also be equipped by the Union Electricitäts Gesellschaft whose interests here are carefully watched by their local manager, Mr. Emil Bjorkegren. It is interesting to know that this accomplished gentleman obtained his electrical training originally in the Thomson-Houston Co.'s shops in Lynn. This helps to account for the up-to-date customs and the speed of 12 to 15 miles per hour cars make. The Americans are looking with longing eyes to trade with Germany and we noticed that the dining car en route to Vienna was built at the Jackson & Sharp Co.'s works in Wilmington. There appears to be no good reason why American street car builders should not be able to furnish electric cars to Germany, considering the experience they have behind them.

In the car company's hospital a curious relic is shown. It is one of the old omnibusses some of which are still in use. There are four wheels with which it runs along the car track and then there is a fifth wheel which can be raised or lowered. When the bus is running properly, its fifth wheel is raised, but should the bus run off the track the fifth wheel is lowered and by its aid the bus is again put back on the track.

THERMO-ELECTRIC PHENOMENA BETWEEN TWO ELECTROLYTES.

M. Henri Bagard in the *Ann. Chim. Phys.* writes that in continuation of his researches he has determined the thermo-electric E. M. F. in the cases of a number of couples consisting of two electrolytes. The E. M. F. is in all cases, as with the metals, a function of the second degree of the temperature, and very frequently the existence of a neutral point was observed somewhere between 0 deg. and 75 deg., the limits of temperature of the experiments. In the case of two solutions of the same salt of different degrees of concentrations, the current always travels across the heated junction from the dilute to the concentrated solution. Becquerel's law of intermediate substances and the law of intermediate temperatures are found to hold good. There is a simultaneous inversion of the thermo-electric E. M. F. and of the Peltier effect at the point of contact of the two electrolytes, and an electrical transference of heat in these liquids.

LIMITS OF ELECTROLYSIS.

M. Marcellin Berthelot, in *Ann. Chim. Phys.*, states that he has formerly shown by experiment that in the electrolysis of an alkali salt, of which neither the acid nor base is oxidized or reduced during the operation, the minimum E.M.F. necessary for electrolysis is the sum of two equivalent quantities—the one being the heat absorbed in the separation of the acid and the base in dilute solution, the other the heat of decomposition into oxygen and hydrogen of the water holding the substance in solution. In the case, for instance, of potassium sulphate in dilute solution the sum of the two quantities of heat is $15.7 + 34.5 = 50.2$ cal. when one gramme of hydrogen is liberated. This is equivalent to 2.20 volts, a number which Le Blanc has obtained by direct observation. Other results are quoted in support of the above law, which the author maintains as an empirical law, independent of any hypothesis regarding the condition of the dissolved salts in solution.

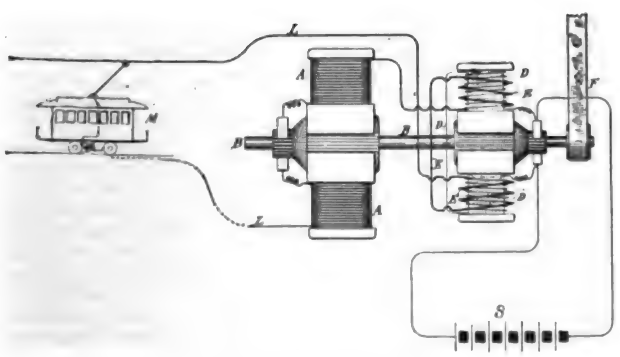
ELECTRIC TRANSPORTATION DEPARTMENT.

CURRIE'S RAILWAY POWER STATION STORAGE BATTERY ARRANGEMENT.

To secure uniformity in engine load in railway power stations the storage battery suggests itself and the results obtained in the few stations so equipped here and abroad leave little room for doubt that this method will come into more general use at no distant day.

The usual practice in stations so equipped has been to connect the storage battery with the main or working circuit to supplement the dynamo, but under ordinary conditions this would necessitate a battery of very considerable voltage, and increases the tendency to leakage, short-circuiting, and injury to the plates. To obviate this and to secure a better regulation than that which is dependent upon fluctuations in the speed, which it is one object of the system to prevent, Mr. S. C. C. Currie drives two mechanically-connected dynamo electric generators, mounting the two armatures on the same shaft, and using one to supply current to the external circuit, and the other to charge storage batteries which are permanently connected up in its circuit.

The arrangement is shown diagramatically in the accompanying engraving. The main generator A which supplies the line has mounted on the same shaft the armature of a second generator C having a compound-wound field, one coil D being in shunt to the armature and of fine wire, while the other coil E is of shorter heavier wire and connected up in the main circuit L L of the generator A, the winding being such that the main current has a tendency to demagnetize the field of the second generator. In the circuit of the second generator is the storage battery S of a



CURRIE'S RAILWAY POWER STATION ARRANGEMENT.

capacity calculated to meet the requirements of practical working.

In illustration of the operation of the system, suppose the power of the prime motor be maintained at about fifty horse-power, while the load on the generator A varies from double this amount to nothing. When the load on the generator A reaches or is in excess of the limit of the engine, the heavier current on the line lowers the electromotive force of the second machine, so that it becomes a motor and is driven by the battery. On the other hand, when the load is light the electromotive force of the second machine rises and it becomes a generator, charging the battery. In practice with due observance of proportions it would be fair to assume that the total power required from the battery to the shaft would not exceed twenty-five per cent. of the total power transmitted from the shaft to the line, so that with a daily output of one thousand horse-power hours not more than two hundred and fifty horse-power hours would be required for the battery.

Such a combination necessarily involves a certain loss, both in charging the battery by the generator and in running the motor by the battery; but allowing for such losses and also the small loss by the neutralization of the field of the second generator, there are still many cases where the total saving from being able to maintain a steady load on the prime motor would much more than compensate for the losses named.

A NEW PHILADELPHIA GAME.

PHILADELPHIA CHILDREN have a new and delightful game called "Trolley Car." It is played by from two to twenty juveniles, all but one of whom sprawl on the pavement, while the other pushes a baby carriage over their prostrate forms.

ELECTRIC TRAMWAYS OF LONDON AND BOSTON.

IN a paper read before the Electro-Technical Society of Cologne, Mr. G. Kapp makes an interesting comparison between the tramway systems of London and of Boston. Though the former city covers about ten times the area of the latter, the length of lines in the two is nearly identical, Boston having about 270 miles of line, and London about 20 miles less. The number of car-miles run in Boston is 18,750,000 miles, and in London about 21,870,000 miles. But though the density of traffic is thus greater in London than in Boston, the latter makes much more satisfactory returns to its shareholders, the averaged dividend there being 9 per cent. on a capital account some 25 per cent. more than in London, where, nevertheless, the shareholders have to be content with but 8¼ per cent. or so, on their capital, which, moreover, from the recent decisions of the courts, appears to have been staked on a very precarious security. The working expenses of the two lines are practically identical, but in Boston they only amount to 68 per cent. of the receipts in place of 82.7 per cent. as in London. The Boston lines are, it should be added, worked on the trolley system, whilst, with the exception of a small proportion of cable line, the London tramways are worked entirely by horse traction. Mr. Kapp states that in Germany there are now some 212 miles of line worked electrically, the rolling stock consisting of 540 motor cars and 420 ordinary ones. An additional 112 miles of line are, moreover, now in course of construction, and will find employment for 290 motor cars. Some of these lines have very heavy grades; in particular, there is one in Barmen where an incline of 1 in 5 is surmounted, a rack rail being used, as the adhesion is, of course, insufficient. Nevertheless, quite steep slopes are worked without calling in the aid of such special devices, there being a slope of 10 per cent. on the Remscheid line. The ratios of expenses to receipts on these lines are put at an extraordinarily low figure, as little as 18.4 per cent. in some cases. In certain of the smaller plants the sudden and great variations in the demand for current have proved troublesome, and have led to the use of accumulators as regulators. At Hirslanden, near Zurich, for instance, the plant includes two 90 horse-power engines, one of which is used as a stand-by. There is also a battery of accumulators, consisting of 800 elements, which in normal work can supply a current of 81 amperes. The current on the line ranges, with the nine cars in use, from 50 to 110 amperes, but occasionally reaches as much as 200 amperes. Automatic apparatus regulates the supply in such a way that the dynamo gives a constant current of 80 amperes, any deficit being made up by the batteries.

WILL MR. PAYNE KINDLY EXPLAIN?

H. R. Payne, of Dunkirk, N. Y., one of the oldest locomotive builders in America, says: "It will be many years yet till electricity supersedes steam on our railways, unless some radical changes can be made. Experiments recently made show that it is possible to work an electric locomotive, but the expense of a few collisions would bankrupt any road."

THE TROLLEY LINES BETWEEN WASHINGTON AND BALTIMORE.

A special dispatch from Baltimore says: The contract for the building of the roadbed of the Columbian & Maryland Electric Railway, which will connect Baltimore and Washington, over a thirty-six mile route, has been awarded to E. D. Smith & Son, of Philadelphia. The cost of construction, including a branch to Ellicott City, will be about $3,000,000. The work will begin at once, and is to be completed within a year.

A contract for a second electric road between Washington and Baltimore is expected to be signed at once in New York. The enterprise is backed by the Washington, Sandy Springs and Baltimore Electric R. R. Company. Allston Gerry and Nathan G. Miller, of New York, and James B. Colegrove and George S. Chase, of Washington, have agreed to take an issue of $750,000 of thirty-year 5 per cent. gold bonds, the proceeds of which are to be employed in building the line. The capital stock of the company is $1,500,000.

In planning the Sandy Springs route no attention has been given to the possibilities of through business between Washington and Baltimore, but the aim has been to traverse a developing section not now reached by railroads. The Columbian and Maryland Line, on the other hand, has been surveyed with a view of running express trains between the two cities over the shortest possible route in competition with the Pennsylvania and Baltimore & Ohio Railroads.

FENDERS ORDERED ON ALL MASSACHUSETTS STREET CARS.

The railroad commissioners of Massachusetts have issued an important circular, which affects every street railway in the state. Under an act passed by last year's legislature the commissioners gave a number of hearings to persons interested in railways and others relative to equipping street cars with fenders which would be capable of saving life.

The result of these hearings and investigations by the railroad commissioners is the order sent out to every street railroad in the state. The roads have until Nov. 14, 1895, to comply with the order, which is as follows:

"Ordered, That the following requirements and regulations be prescribed and notified to the several companies relative to the subject matter of the aforesaid act:

"Regulations for the equipment of street railway cars with fenders and wheel guards.

"1. All cars run by a street railway company on a highway, town way or traveled place (excepting cars run by horse power, cars run only as trailing cars, and, until the further order of the board, cars run wholly within the limits of towns whose population is less than 7,500 each), shall be equipped with fenders and wheel guards in accordance with one of the two following methods: Either (1) with a fender at the front of the car (going in either direction), and also with wheel guards underneath the car; or (2) with a fender at the front of the car of such design as to serve also as a wheel guard.

"In the first case (1) the fender shall consist of a platform, netting, or other similar device, constructed and arranged so as with reasonable certainty to pick up a person who is run into while standing, but to pass over a person who is lying on the ground, without probable injury to the person in either contingency; and the wheel guards shall be of such construction and arrangement or method of operation as to prevent, so far as practicable, a person who has fallen or been thrown down from being run over by the wheels.

"In the second case (2) the fender shall be of such construction, arrangement and method of operation as not only to pick up as aforesaid a person who is run into while standing, but also to prevent as far as practicable a person who has fallen or been thrown down from getting under the car and being run over by the wheels. This form of fender shall accordingly include a device by which, in case of emergency, it can be lowered by the motorman, and when lowered held down close to the ground.

"2. These regulations shall take effect on the 14th day of November, 1895, and may be modified from time to time, in general or in particular, as experience and the public safety may seem to the board to require.

"Note—There are, it is well known, many kinds or forms of fenders and wheel guards. It can, perhaps, hardly be expected that any of them will afford absolute protection under all circumstances. Some of them have shown or promise reasonably good results, but no one fender or wheel guard has as yet been proved to be so unquestionably superior to all others, tried and untried, as to justify the prescription of its sole and exclusive use.

"Under these circumstances it has seemed to the board, in the performance of the extremely perplexing task imposed upon it by the statute above cited, to be wiser and better to define the methods of protection, and point out the essential features or requisites of the appliances which must be adopted than to prescribe the use of any particular invention or device. There are obvious reasons why the companies should not be compelled to deal with a single patentee. It is, moreover, desirable that different types, within the lines prescribed, be tested by actual use. Only in this way will the best device be found out.

"It is expected, therefore, that the several street railway companies, in the exercise of a careful judgment, in good faith toward the public, and upon their own legal responsibility under the statute, will select and apply to their cars such fenders and wheel guards as come within and satisfy the requirements of the above regulations."

HE THINKS FENDERS OF LITTLE SERVICE.

At the meeting of the New York Assembly special committee of railroad investigation on August 7, in Brooklyn, John Steiner, a railroad man for thirty-four years, twenty-nine of which have been spent in the service of the Brooklyn and Newtown company, testified that he was a motorman and could stop a car running at the rate of ten miles an hour in fifteen or sixteen feet, and a car running at six miles an hour in from six to ten feet. He considered vestibule cars bad for crowded cities, because they are so constructed as to obscure the view of the operator, especially if the weather be cloudy. Again they prevent a motorman from hearing sounds on either side of him, which is of importance if the car is to be run with the greatest safety. Asked as to what form of fender he most favored, Mr. Steiner said he was against all fenders, believing none of them to be of any account. The best fender, he added, was a level headed motorman. In all the years he has been operating cars he has never had an accident.

ANOTHER "PENNSY" TROLLEY BRANCH.

A special dispatch from Mt. Holly, N. J., of Aug. 2 says:—That Medford is to be connected with Mt. Holly by trolley there is no longer any doubt. A reporter caught a hint yesterday that the railroad company was getting ready to wire the road between Mt. Holly and Medford, and a close investigation confirmed the rumor. The same crew that wired the Burlington road will do the work, and the material is now being prepared. The indications are that the work will be under way within ten days.

The company is delighted with the results of the Burlington experiment and, it is said, has in contemplation the question of a trolley to Vincentown. As the power plant has already been built for the one road, it would, of course, be a matter of economy to operate the three roads. The Burlington road carried nearly eleven hundred passengers on Sunday and has done a wonderful business daily since it started. The company is having several other cars made and will not only give Medford and Lumberton a good service, but will increase the Burlington service if the travel demands.

THE TROLLEY IN BINGHAMTON, N. Y.

The Binghamton Railroad Company, organized under the laws of the State of New York, is the outgrowth of the consolidation of all the street railroads of this city. Since the last annual report, issued July 1st, 1894, the road has shown the remarkable gain in gross earnings of seventeen per cent., and a gain in net earnings from operation, including taxes, of twenty-three per cent. The percentage of operating expenses to earnings for the past year was 57⅝ %. These results have been accomplished with the same trackage, under the same conditions and in the face of the prevailing financial depression and the most severe winter the road ever experienced. After paying interest on funded debt amounting to $31,500, there remains a dividend upon the capital stock of over five per cent. G. T. Rogers is president of the road; C. O. Root, secretary; J. B. Rogers, treasurer and J. P. E. Clark, general manager.

STEAM RAILROAD MRS. PARTINGTONS.

A new political organization has been formed in Jersey City, composed entirely of the employees of the various steam railroads whose eastern terminals are in this county. It is claimed that all of them are represented in the movement. The members say they were compelled to organize to protect themselves from trolley roads, whose great increase of late is likely to reduce the wages of railroad men by reducing the volume of steam railroad business. The resolutions adopted pledge the association to support no candidate who will not pledge himself to oppose any legislation in favor of electric roads. The members say they took an active part in the election in Hudson County last year, and that all the successful candidates were indorsed by them. Four were Democrats, and eight were Republicans.

A LARGE ELECTRIC ELEVATOR FOR TAMPA, FLA.

A special dispatch from Tampa says: The foundation for the electric elevator at Port Tampa is being driven and prepared, and the machinery has begun to arrive. D. W. Shea, the electrician of the Plant System, who suggested this method of operation as superior to the use of steam, has just returned from Pittsburg, where he has been to witness the testing of the apparatus, which was in every respect highly satisfactory. The capacity of this elevator will be 240 tons or twelve cars per hour; it will require 100 horse power to operate it, which will be supplied by alternating current from the electric light station at Port Tampa City, 10,000 feet away, where they are now making the necessary arrangements for placing the generator and switchboard. The erection of the machinery will be begun in a week or ten days and the elevator will be ready October 1. The old steam elevator will also be run by electricity. After figuring out all the details and allowing a margin for unforeseen contingencies it is estimated that the saving in expense will be 25 per cent. To the shipper it will be a great advantage, for it will greatly expedite the loading, and thus lower freight rates.

"A GOOD THING—PUSH IT ALONG."

Mr. H. Bottomley of the Marlborough, Mass., Electric Co. writes: Your "Data Sheets" idea is a good thing—push it along. For ten years I have collected data of all kinds; and now, when I want to refer to it I am obliged to look over several imperfectly catalogued books, and it's "dollars to doughnuts" that I cannot find what I want without much labor and time. Like Micawber, I have waited patiently for "something to turn up" in the same line that is better than mine, and now, like Oliver Twist, I call for "more." Please send me a morocco filing case.

TELEPHONY.

MEETING OF THE EASTERN TELEPHONE PROTECTIVE ASSOCIATION.

THE second meeting of the Eastern Telephone Protective Association was held in the Postal Telegraph Building, New York, on August 15, though the organization was not completed at that time owing to the absence of some of the proposed members. Another meeting will be held on Aug. 20 to ratify all actions already taken and to come to some definite arrangements as to the appointment of counsel to defend all suits brought by the American Bell Telephone Co. against any alleged infringers of the Berliner patent.

LIKES THE TRANSMITTER SET FORWARD.

"There is one thing about the new telephones," remarked a gentleman who has occasion to use that instrument a great deal, "that I like very much, and that is the change made in the transmitter. Formerly the transmitter was set back toward the box proper of the instrument and to speak into it a person had to put himself in a strained position that was very disagreeable as well as tiresome, and even then the voice could not be heard any too distinctly. But in the new pattern the transmitter is set on blocks which throw it several inches from the box of the instrument and obviate the former disagreeable features."

RUMORS AS TO AMERICAN BELL.

THE *Beacon*, of Boston, says on alleged good authority that the American Bell Telephone Co. will remove to some other state because of the restrictions placed upon the company in the matter of increasing its capital. The failure of the large stockholders to subscribe for the new stock recently offered them is said to be due to their knowledge of the fact that the officials of the company are discussing the advisibility of taking out a charter in a state where the hostility to corporations is less pronounced than in Massachusetts. In commenting further upon the enforced auction sale of about 6,500 shares of the new stock, the *Beacon* says: "The disposal of so large a block of stock by auction, however beneficial it may be to the community at large, as compared with the old method of issues of rights to stockholders to subscribe at par, is in one way unjust to the smaller holders of the stock. Thus, no one at auction can buy less than 50 shares. And yet the auction is in the very nature of the case likely to create lower prices for the stock than those prevailing in the open market, either before or after the sale. A plum thereby is offered to the heavy purchasers, who are in a position to make a handsome turn by grabbing the auction stock and then manipulating the market to a higher level and selling to their less wealthy fellow-stockholders."

TELEPHONE NOTES.

BANGOR, ME.—The Dirigo Telephone Company has obtained a license to construct a system in Bangor.

BALTIMORE, MD.—Mr. Fred B. Hubbell, of Baltimore, has been elected president of the Home Telephone Company in place of Mr. Franklin Noble, of New York.

TRENTON, N. J.—The new telephone company has enrolled some 400 subscribers in its scheme to supply a cheaper telephone service in this and adjoining states. It is proposed to begin in this city when 500 names have pledged themselves to the new undertaking.

LACONIA, N. H.—Telephone communication between Laconia and Centre Sandwich has been completed. The distance is twenty-four miles. Offices have been located at Centre Harbor, Moultonborough, Lower and Center Sandwich.

WATERVILLE, ME.—The New England Telephone and Telegraph Company has just completed a metallic circuit from Waterville to Pittsfield. A new copper metallic circuit has also been connected between Waterville and Brunswick, which now makes a continuous copper metallic circuit from Pittsfield to Portland.

LITTLETON, N. H.—Telephone men are improving the lines in this vicinity. New poles are being set over most of the line between Woodsville and Lancaster, to carry a copper wire. With the completion of the metallic circuit to White River Junction, this section will have long-distance connection with all parts of the country.

WATERTOWN, N. Y.—The Watertown Telephone Exchange Company has been incorporated to maintain lines connecting Watertown and towns and villages of Jefferson county, with a capital of $50,000 and directors, A. L. McCrea, Jr., and J. M. McIntyre, of Gouverneur; John C. Streeter, Samuel Felt, George C. McMullin, James L. Newton and Francis A. Sherman, of Watertown.

BOWLING GREEN, KY.—The line to Glasgow has been completed.

NAUVOO, PA.—The new telephone line is in operation from Nauvoo to Wellsboro, Tioga county.

VICKSBURG, MICH.—The Southern Michigan Telephone Company has opened its local exchange here for business.

PAWTUCKET, R. I.—The work on the conduits of the Providence Telephone Co. is going on rapidly and the conduits already built have been connected.

PAUL'S VALLEY, TEX.—A contract has been made with Grant & Co. for a telephone line from Paul's Valley to McGee and Center, thirty miles distant, using the National telephone.

COLLINS, MO.—A telephone line has just been completed connecting this place with Osceola, which will give connection with Osceola, Loury and Appleton City line.

LATROBE, PA.—The Telephone Exchange Company, of Latrobe, Westmoreland County, has been formed; capital, $5,000. Joseph E. Barnett, of Latrobe, is president of the latter.

SAVANNAH, GA.—The Bell Telephone Company in Savannah will lay about two miles of conduits and put part of their wires underground.

HAVERHILL, MASS.—The Common Council has voted to postpone indefinitely action on the ordinance to put the telephone wires underground.

CORNING, N. Y.—A project is on foot to erect a telephone line from Corning to Hornby Forks. It has been suggested that the citizens of Hornby build the line and take half the receipts. It will cost from $100 to $125 per mile for poles and wire.

INDIANAPOLIS, IND.—An ordinance has been prepared which will put all wires running through the city in the mile limit underground. This will include telegraph, telephone and electric light wires.

PETERSBURG, VA.—The Southern Bell Telephone Company has notified its subscribers in Petersburg that the price of telephones for stores would be reduced to $18 per annum and those of residences to $10 per annum.

RHINEBECK, N. Y.—The Hudson River Telephone company, through their representative Mr. H. C. Mackey, have secured enough subscribers to practically insure the establishing of a local exchange.

WHITEHALL, N. Y.—Since the Hudson River Telephone Company decided to extend the long distance service to Whitehall and Rutland, a plan is on foot to build a new line from Whitehall to Montreal.

CUMMINGS, N. D.—The Northwestern Telephone Co. now have a large crew of men setting poles from Cummings to Mayville. They expect to have the line in operation by the middle of August.

LEAVENWORTH, KAS.—At a meeting of the police commissioners an agreement was made with the People's Telephone Company to place eight or twelve telephone alarm boxes in various parts of town for the convenience of the police patrol.

SOUTH BEND, IND.—The South Bend telephone company has been formed. Capital stock, $50,000. Directors, C. B. Van Pelt, Louis Nickel, jr., W. H. Longley, E. G. Waldron, W. L. Kizer and F. W. Martin.

THE HOME TELEPHONE CO., of Mobile, Ala., Paul Minnis, general manager, are now rapidly installing a telephone exchange to be ready early in September. The switchboard for 600 subscribers, will be furnished by the National Telephone Mfg. Co., of Boston.

DETROIT, MICH.—Mayor Pingree has approved the Harrison Telephone Company's franchise, making it a law and has vetoed the Brown Loud Speaking Telephone Company's ordinance, rendering it valueless, unless twenty-two aldermen pass it over his veto.

LANSDOWNE, PA.—The Delaware County Telephone Company is the name of a local telephone company being organized to operate at Lansdowne and vicinity. The object is to give cheaper service and direct connection to Philadelphia and points on the long distance wire. The rates will be $2.50 per month for stores and $1.50 per month for private dwellings.

RICHMOND, VA.—There is a big telephone fight on in Richmond. There are now two new companies soliciting subscribers with a view to asking the Council for franchises. One is the Standard Company, and the other the Home, of Baltimore, which was chartered under the laws of West Virginia. Both offer business telephones at $3 per month and residence service at $2 per month. The present Bell Company charges $64 for business and $40 for residence phones.

BLOOMER, WIS.—The wires and electric appliances for a new telephone exchange at Bloomer have arrived.

NASHVILLE, TENN.—A new telephone company is being formed and it is said 1,200 subscribers have been secured.

BRATTLEBORO, VT.—The Brattleboro telephone exchange has 206 subscribers and a new switchboard has been ordered.

SHELDON, MO.—Sheldon will soon become connected with Nevada by telephone line. The line will be built by subscription, Sheldon having subscribed $375.

SIOUX CITY, IA.—The Home Telephone company is putting in two new sections of its switchboard, and will have 500 telephones connected up this week.

RED HOOK, N. Y.—A telephone company has been formed at Red Hook, whose intention is to connect that place with Barrytown, Barrytown Corners, Cedar Hill, Annandale and Madalin.

NEW HAVEN, CONN.—The Southern New England Telephone Co. has made an arrangement with the state whereby the line to Camp Coffin will be rebuilt.

COLUMBUS, MISS.—The Citizens' Long Distance Telephone and Telegraph Co.'s plant is rapidly nearing completion, and it is expected that within one month the exchange will be established and the entire system in operation.

OSKALOOSA, IA.—Manager H. W. Comstock, of the old telephone company, is in receipt of advices to the effect that the company will soon begin the work of putting in the "return system" of wiring for the Oskaloosa exchange.

CATLETTSBURG, KY.—The stockholders of the Catlettsburg telephone line held a meeting the other day, and decided upon the placing of a telephone line up the river connecting with the new Huntington company's service which will be extended to Ceredo.

CHILLICOTHE, O.—The Home Telephone Co. of Chillicothe, Ohio, has recently constructed a new telephone exchange and lines in that city, in opposition to the old company, and with rentals at $1.50 for residences and $2 for business houses, has over three hundred subscribers under five years contract.

COLUMBIA, S. C.—A commission for a charter has been issued to the Columbia Telephone Company of South Carolina. The corporators named are: W. Y. Abraham, W. B. Lowrance, F. D. Kendall, A. R. Stewart, R. J. Johnson, T. J. Harper and J. B. Friday. The capital stock of the company is to be $5,000, and the right to increase it to $50,000 is given.

LANSING, MICH.—The Lansing telephone exchange is a body corporate. It became so with the filing of its articles of incorporation and the election of its officers. Jacob Stahl was elected president of the new company and D. A. Reynolds manager. The capital stock of the company is $30,000 of which $20,000 is paid in.

KINGSTON, N. Y.—The battle between the Bell telephone monopoly and the new Standard Telephone Company is about to begin here. The Hudson River Telephone Company, the local branch of the Bell system, was charging $72 a year, and tolls on all messages outside the city until within a few weeks. Now it has reduced rentals to $25 a year, but retains the tolls.

SPRINGFIELD, ILL.—A bill has been introduced in the House of Representatives to regulate telephone companies in Illinois. It fixes the maximum rates as follows: In cities of 1,000,000 or more inhabitants, $78 per annum; in cities of more than 500,000 and fewer than 1,000,000 inhabitants, $66; in cities of more than 100,000 and fewer than 500,000, $48; in cities of fewer than 100,000, $36.

ELIZABETH, N. J.—The City Council has granted the Elizabeth Mutual Telephone Company a franchise to operate a telephone system throughout the city. An injunction was placed on the company by the New York and New Jersey Telephone Company recently, which was dissolved when the former company reorganized. The new company will at once commence the erection of poles, etc. The capital stock is $30,000.

FALL RIVER, MASS.—The work of putting the telephone wires underground has begun. It is being done by the National Conduit and Construction Company of New York City. The total length of ducts is 55,095 feet; total length of trench 7,975 feet. The latter will be from 4 feet to 10 feet deep according to the number of wires required to be buried. In width the trenches will vary from 2½ to 4 feet.

KINGSTON, N. Y.—An arrangement has lately been entered into between the officers of the West Shore Company and representatives of the Standard Telephone Company, under which the plant of the former company will become the property of one of the branches of the latter and the lines of the West Shore will be completed and put in operation throughout the entire territory covered by that organization.

MOBILE, ALA.—The use of the telephone system in connection with the patrol boxes has been strongly recommended.

DETROIT, MICH.—The Harrison Telephone Co. has accepted the franchise granted by the city.

GREENSBURG, IND.—The Greensburg Telephone Company has built entirely new the line between Milroy and Richland. This line was first built some six years ago.

NEWBERNE, N. C.—A telephone exchange is to be erected here. The whole equipment will be manufactured at Fayetteville, it is said.

DOUGLAS, MICH.—A telephone company has been organized at Douglas to connect Douglas, Saugatuck and Ganges with the outer world.

CHAMPAIGN, ILL—The Phœnix Telephone Company of Champaign has been making very rapid progress in the erection of poles and stringing of wires.

WESTERLY, R. I.—The Rhode Island Granite Works has been granted permission to erect telephone poles along Oak and Tower streets to its Red Quarry.

ANDERSON, IND.—J. M. Overshiner & Sons have entered extensively into the telephone business. They purchased the telephone at Elwood from the Pana Telephone Company and are also constructing an exchange at Logansport.

SANDUSKY, O.—The ordinance which grants to the Sandusky Telephone company rights to put up poles and string wires through the streets of Sandusky was passed at the regular meeting of the city council.

CLEBURNE, TEX.—A telephone company has been organized. Nearly all the stockholders are Cleburne men. The National Telephone Company of Boston is the promoter. The plant will be put in at once.

APPLETON, WIS.—F. L. Humes, of the National Telephone Co., has petitioned the council for permit to come into the city. This company will soon have an exchange in operation at Waukesha and at once go to work building one at Fond du Lac.

DRISCOLL, TEX.—The telephone line is now completed to Alice. The stockholders have elected the following officers and directors: L. K. Foster, president; G. W. Newberry, vice president; N. H. Brown, secretary and treasurer; John Wade, T. C. Wright and George Hobbs, directors.

TORONTO, O.—The city council has passed an ordinance granting franchise to the Phoenix Telephone Company of Steubenville to erect and maintain lines in this city. This company will embrace Steubenville, Toronto, Wellsville and Liverpool, north; Mingo and Brilliant, south; Richmond and Wintersville, west.

WEST BOYLSTON, MASS.—The New England Telephone company is about to build a house on the line of the Central Massachusetts railroad near the Clarendon Mills at West Boylston, for long-distance telephones in anticipation of use by the Metropolitan officials.

INDIAN FIELDS, N. Y.—The stockholders of the Coeymans and Westerlo Telephone Company have elected the following officers: President, G. C. Lamoreau; vice-president, A. D. Briggs; secretary, Lindsey Green; treasurer, Stephen Tompkins; directors, G. C. Lamoreau, Will Cole, Jr., Vincent Snider, J. M. Nodine, B. T. Briggs, A. D. Briggs, Lindsey Green, W. Caswell, H. S. Hempstead, H. N. Johnson, M. S. Reid and J. W. Cowen.

COLUMBUS, IND.—The Citizens' Telephone Company (the Harrison system) has completed and opened its large exchange in Columbus and has reduced the rate of the Central Union from $36 to $27 per annum for business houses, and from $36 to $18 for residences. The last named company now announces an open rate of $12 for business houses and $8 for residences. The country line of the Harrison system has been completed to Clifford, St Louis Crossing, Hope, Nortonburg, and Flatrock.

IOWA FALLS, IA.—The Western Telephone Company is a new competitor in that line in this state and Minnesota and promises to become one of the leading organizations of this class in the west. The officers of the company are: J. F. Case, Sumner, Ia., president; C. Webster, Waucoma, vice-president; T. H. Potter, Corwith, secretary; T. H. Way of Britt, treasurer. It is the intention of the company to push north as far as Minneapolis and St. Paul, and as far east as Chicago.

BALTIMORE, MD.—At a meeting of the directors of the Standard Telephone Company, which proposes to establish a new telephone system in Baltimore, it was decided to contract with a New York construction company for the building of its line. Officers were elected as follows: President, John N. Woodland; vice-president and general manager, George W. Cross; secretary, Bruce B. Gootee, and treasurer, Elbridge S. Johnson. It was stated that the contract is about closed for building the long distance line between Baltimore and Washington.

THE CHOICE OF TRANSFORMERS.[1]

BY PROF. D. C. JACKSON.

In order to place before you independent data representing all the American transformers of moderate capacities I will give the results of a long and carefully carried out series of tests made by Mr. A. H. Ford in the laboratory of the University of Wisconsin. For these tests transformers of fifteen hundred watts capacity, as nearly as possible, were procured directly from the manufacturers within about a year from this date, so that the tests may be presumed to represent the latest and best designs which are now supplied. These transformers are from the most prominent makers and in fact include all important makes of American transformers with two or three exceptions. The results of the tests are given in the attached table. (Table I.) These results, I find, do not differ very widely from those published by the Fort Wayne Electric Corporation in a small blue printed pamphlet, which however, contains tests made by the company upon only a few of the makes of transformers included in my table.

TABLE I.

No.	Watts capacity.	Open circuit current. F=125	Open circuit current. F=60	Watts Iron loss. F=125	Watts Iron loss. F=60	Watts Copper loss full load.	Total drop.	Efficiencies full load. F=125	Efficiencies full load. F=60	All day. F=125	All day. F=60
1	1250	.043	.066	37	48	30	2.5	96%	94%	85%	83%
2	1500	.076	.124	50	71	45	3 5	95	94	85	81
3	1500	.053	.100	32	46	33	4 0	96	95	89	85
4	2500	.230	.540	185	290	44	2 5	92	89	77	68
5	1800	.075	.600	58	109	67	5.0	94	92	85	75
6	2000	.055	.091	42	56	55	5.0	95	94	89	86
7	1000	.028	.064	24	28	33	3.0	95	94	87	86
8	1500	.073	.113	57	76	31	2.5	94	93	83	79
9	1500	.077	.144	43	55	28	3.0	95	95	86	84

The data for each transformer is given for tests upon two frequencies,—125 and 60 periods per second, respectively. Efficiencies have been calculated and are given in the table for each transformer when operated upon each frequency continuously at full load and also when operated at an assumed load which may be taken as an approximation to the average load found on good stations operating twenty-four hours. The latter are called "all day" efficiencies and are calculated as though the transformers ran nineteen hours out of the twenty-four on no load and five hours on full load.

A comparison of the losses of the different transformers and the efficiencies shows in most cases that the transformers with the smallest iron losses give the highest "all day" efficiencies. The effect of the iron loss on the working efficiency depends upon the length of time the plant runs. The waste of power due to the iron loss in the transformer continues as long as current is fed to the primary circuit, consequently a plant which only runs six hours per day will only waste one quarter of the power by the iron loss of its transformer, that it would if operated twenty-four hours per day. The actual number of watt hours used by the customers of the plant might not differ very greatly in the two cases, yet the out-put of the station when run twenty-four hours might be much greater than when run six; the former difference being due to the difference in the amount of power wasted in the transformers. It is therefore evident that extreme care in the selection of the best transformers to be used on an alternating plant which runs all day may be of the greatest advantage. The lower the frequency of the alternating current which is used, the greater are the returns coming from this care likely to be.

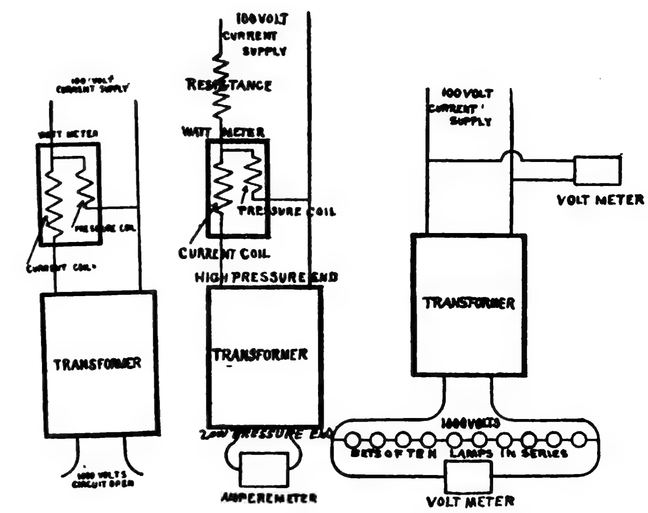
The advantage to be derived by testing every transformer before placing it on the line.—Let us compare transformers Nos. 3 and 4 as given in the table. These are both made by well-known manufacturers. The copper losses at full load do not differ very much, what difference there is being in favor of No. 4. At average loads there would be considerably less difference in these two points. The iron losses, which go on regardless of the load as long as current flows in the primary winding, differ very greatly even if we take three-fifths of the loss in No. 4 as the losses of a 1500 watt transformer of that type. Let us suppose that these transformers are placed on a plant which supplies current twenty-four hours each week day and twelve hours on Sunday, which makes a total of 8,136 hours per year that current would flow in the primary winding of the transformers, and the total number of watt hours wasted by the two transformers is shown below :—

	F. = 125.	F = 60.
Transformer No. 3,	8136 x 32 = 262,000.	8136 x 46 = 374,300.
Transformer No. 4,	8136 x 80 = 651,000.	8136 x 140 = 1,140,000.

In a station which turns out a kilowatt hour for each eight pounds of coal burned (and this in Wisconsin requires the station to be well arranged and the use of coal that costs two dollars and a half or more) transformer No. 4 requires the buying of about a ton and a half of extra coal every year when operated at a frequency of 125; therefore it costs, other things being equal, upwards of four dollars per year more to operate than number three. It would therefore pay well if other things were equal, to buy transformer No. 3, even if its first cost were many dollars greater than that of No. 11. The difference between the transformers is even greater when the frequency is 60.

For every hundred transformers of the types here compared, the generator plant that supplies current to No. 4 must be of 5 kilowatts greater capacity than that required for No. 3, which means an increase of three per cent. in the generating plant; that is, a plant of a given size which has transformers No. 4 must have a capacity for supplying current greater by three per cent., than if transformer No. 3 were used.

Differences sometimes occur between transformers of the same size and same make which are not as great as the differences here shown to exist between numbers three and four, but are sufficiently great to seriously affect their economy. In order to husband the capacity of a plant and to save in operating expenses, it is therefore of importance not only to test transformers of different makes which are presented for sale, but to test each transformer which is put on the line. This may be easily and expeditiously done. To test the iron losses the secondary coil of a transformer should be connected to the regular lighting circuits with an ordinary wattmeter included, and the circuit of the primary coil should be left open ; the arrangement is plainly shown in Fig. 1. The reading of the wattmeter shows the number of watts which are wasted by the iron loss. If the regular wattmeter is too expensive to buy, an ordinary Thomson recording wattmeter, provided a sufficiently sensitive and reliable one



FIGS. 1, 2 AND 3.

is at hand, may be used in place of it, and the record reduced to the basis of one hour. It is needless to say that instruments which are used in such tests as are here proposed, must be fairly reliable.

To test the copper losses in a transformer the quickest and easiest method, which is approximately accurate, is to connect the primary coil of the transformer in series with some resistance (iron wire or lamps) to the alternating incandescent circuit, and short circuit the secondary coil of the transformer through an amperemeter. (Fig. 2.) The resistance should be adjusted until the full load current of the transformer flows through the amperemeter. The reading of a wattmeter so connected in circuit with the primary coil gives the copper loss approximately.

The drop in pressure in a transformer may be measured by connecting the transformer to the lighting circuits and reading the primary and secondary pressures by voltmeter (Fig. 3). The transformer may then be loaded by lamps and the pressure again read, when the drop is at once seen. One voltmeter may be used for this, but two are more convenient.

For your guidance in selecting transformers, I will give you the following data, contained in a table made out by Professor Ryan. The table gives the largest currents which should flow in the 1,000 volt primary of good transformers when the secondary circuits are open.

Watts capacity.	*Leakage current.*
1000	.055
2000	.080
6500	.100
17500	.200

When the low pressure coil is connected to a hundred volt circuit the leakage currents may be expected to be ten times as great.

For intermediate capacities, intermediate values of the open circuit or leakage current may be expected. I will add to this

1. Abstract of a paper read before the Northwestern Electric Association.

the values of the iron loss which should not be exceeded in thoroughly good transformers.

Watts capacity.	*Iron loss.*
1000	30
1500	40
2000	50
2500	60
4000	80
6500	100
17500	150

The copper losses in transformers of all sizes should never exceed 3½ per cent. at full load, and ought to be between 1½ and 2½ per cent. The total drop in secondary pressure due to loading a transformer, if the primary pressure is kept constant, ought not to exceed 3½ per cent.

ALTERNATING VS. CONTINUOUS CURRENT DISTRIBUTION AT NIAGARA FALLS.

THE work at Niagara has given rise to several controversies and it seems there are still points on which there is a difference of opinion among those who were consulted in the early stages and in the carrying through of the work. Recent issues of the London *Times* contain a number of letters of a highly interesting character bearing on the history of the adoption of the alternating current at Niagara, which, in view of the importance of the subject and the eminence of the parties in controversy, we print below in full:

YOUR New York Correspondent lately announced the successful commercial delivery of electric current from the great 50,000-horse power generating station at Niagara Falls to the first consumers, who use it for making aluminum. I also have received reports of the thorough success of the practical working, and it will be interesting to many of your readers to know wherein the novelty of the work consists, and the value of the results to the whole world.

When I designed the 5,000-horse power dynamos the largest in existence were of 1,500-horse power. The transformers which we employ, as well as other machinery, are also of far greater magnitude than any previously made, and this is part of the reason why the cost of these works is far below what any other engineer has been able to approach. There was nothing experimental in going to these large sizes; the nearest approach to experimental work was when I settled upon the machines for converting alternating into continuous current for the aluminum works, and these have now justified my choice. Such machines on a small scale were shown by Schuckert at the Frankfort Exhibition of 1891; but I took upon myself a great responsibility when making the first commercial use of them on so great a scale—four machines, each of 150 volts and 2,000 amperes. I selected as manufacturers the General Electric Company of America, and they deserve the greatest credit for the result. This Company has also made some novel and excellent machinery which enables us to supply electrical energy at variable pressure to the 1,000-horse power electric furnaces of the Carborundum Company. I will not refer to matters which I had to arrange for, but which are not yet completed. These include transmission of electrical energy to Buffalo and its distribution; also the machinery for adapting the current for arc lights, for incandescent lights, for electric tramways, and for factories and mills. I mention these only to show the variety of requirements which had to be met, with strict attention to cost. Any customer may now ask either for continuous or alternating current at any fixed electrical pressure, or even at variable pressure. My solution of the problem lay in (1) the selection of alternating currents, and (2) the reduction of speed of alternations as low as was possible, and (3) additional safety was insured by my refusal to allow live circuits to be suddenly opened or closed. If this last policy be not continued the directors will have themselves to blame for trouble which must arise.

At the time when I decided upon alternating currents (which had not then been practically used for power purposes), many predicted failure, and some (including my friend Lord Kelvin) have continued to do so. Again, when I adopted low frequency, it was so generally condemned that I claim some foresight in having recognized its merits. I predicted low cost, high efficiency, and increased safety as the results of low frequency, and in practice I have been altogether confirmed. The price charged (with handsome profit) is half a farthing per Board of Trade unit, for which English companies (under more difficult conditions, it is true) are charging about 6 d., and from the time of the inception of this gigantic and novel plant until its commercial working at the present time there has not been a single hitch or mistake to correct.

The Niagara Company make a greater profit by not going to great distances, as it costs them less to supply it near at hand. There is no difficulty or experiment in going to great distances; it is merely a question of expense and of the value of power at the place to which it is transmitted. There are plenty of places in the world where it will pay well to carry electrical energy 400 or 500 miles. I have no hesitation in saying that the low cost and perfect success, practically and commercially, of the Niagara Works opens a new era in the world's industrial evolution.

GEORGE FORBES.

LONDON, July 25, 1895.

A letter by Mr. George Forbes in your yesterday's issue contains the following statement:—

"At the time when I decided on alternating currents (which had not then been practically used for power purposes) many predicted failure, and some (including my friend Lord Kelvin) have continued to do so."

This is not correct so far as the inclusion of my name is concerned. It is true that I advised the directors not to adopt the method of alternate currents; and the correctness of my advice is now illustrated by the fact that in the first practical use of the power it has been necessary to transform from alternate current to continuous current for the electrolytic smelting of aluminum.

In giving my advice to the directors I told them that they could certainly succeed with alternate current, but much better with continuous current.

KELVIN.

AIX-LES-BAINS, July 28, 1895.

IF Lord Kelvin were at home, with his documents to refer to, he would not have written the letter published in the *Times* to-day. On looking through his press copy-book he will nowhere find that he "told them" (the Niagara directors) "that they could certainly succeed with alternate current." On the contrary, he will find copy of a cablegram, in the summer of 1892, to these directors, declaring my policy of using alternating currents to be a fatal mistake or a disastrous mistake. He will also find the same view supported in a lengthy letter which he wrote at the same date. He will also find that in his letter of November, 1894, he referred to this attempt to save them from disaster. Besides these specific occasions on which he volunteered this advice he took further action in the same direction at various times. This was embarrassing to the officers of the company, and they did not disregard the advice of an authority so eminent without finding sound reasons to justify their conduct, which I need not mention here.

As to Lord Kelvin's suggestion, in the letter published to-day, that it would have been better to distribute to all customers the current required by the Aluminum Company (150 volt, continous current), I can at present only state that it is impracticable, and ask, "how about the 110 volts required for incandescent lighting, the 500 volts required for tramways, the 2,000 volts for arc lights, the 10,000 volts required for transmission to Buffalo, the alternating current required by the carborundum electric furnaces, and so forth?" Nearly every one will now admit that the alternating current alone solves the problem well and economically.

GEORGE FORBES.

LONDON, July 30, 1895.

IN your issues of Saturday, yesterday, and to-day appear letters from Professor George Forbes and Lord Kelvin concerning the adoption of the alternating current for the electric power installation at Niagara, and referring to the advice given by them to the directors of the Cataract Construction Company, which did the work.

As first vice-president of that company, which sought and gladly received the advice of these two eminent engineers, I feel it due to both of them that the facts should be stated briefly as follows:

1. In January, 1891, Lord Kelvin was chairman, and Professor Forbes the submitter of a project, to the International Niagara Commission. At the close of that commission every one condemned and rejected the alternating system, excepting only Professor Forbes and Messrs. Ganz and Co., of Budapest.

2. In January, 1894, the Niagara directors had adopted the alternating system upon the advice of Professor Forbes, and with the concurrence of all the expert advisers, including those who had rejected the alternating system in 1891, excepting only Lord Kelvin.

Lord Kelvin thereupon sent to us a cable, in which he certainly indicated a strong preference for the continuous current, but intended also (as we are now gratified to learn from him) as recognizing that we "could certainly succeed with the alternate current."

3. Our decision was thus made because of the prohibitive cost of the continuous current installation, which in most particulars fully justified the strong preference for it evinced by Lord Kelvin, whose eminent and valuable advice and encouragement we gratefully acknowledge. Except for his early and original support, our plan would have died "a-borning," and we thank him for his continuing interest.

4. But the development of our plan must have been long delayed had it not been for the courage and comprehensive knowledge of Professor Forbes, who alone stood for the absolute

commercial advantage of the alternating current, and for his admirable conception of his 5,000-horse power dynamo, so wonderfully worked out by the Westinghouse Company as to yield 5,315-horse power in the actual test on June 28, 1895.

Professor Forbes is entitled to the credit, as he must bear the responsibility, of the results of the advice given by him as to the three points stated in his letter of July 25: and we have followed his advice, perhaps not as far as his courage would carry him, yet beyond the former practice of the manufacturers, who now fully concur in the wisdom of his recommendations as adopted.

The rotary transformers approved by Professor Forbes and made by the General Electric Company are worthy of the highest praise for both design and execution.

5. In fine, the extraordinary and gratifying progress in the development of transforming apparatus, and a corresponding reduction of cost, have taken away many, if not all, of the reasons which Lord Kelvin gave against the adoption of Professor Forbes' original recommendation of the alternating current, which now, as he truly says, "alone solves the problem well and economically."

FRANCIS LYNDE STETSON.

LONDON, July 31, 1895.

Sir:—LORD KELVIN'S prepossession in favor of continuous currents as against alternating currents is not supported by modern electrical practice, save for the restricted purposes of electrolytic decomposition. On the contrary, for nine-tenths of all other purposes the advantage is found to lie on the side of alternating currents wherever the distance of transmission exceeds a few hundred yards. Lord Kelvin points to the use at Niagara of a special commuting machine to transform alternating currents to continuous, for a certain electro-metallurgic process, as though the fact that it had been necessary to add this adjunct condemned the use of alternating currents. It proves, however, the precise contrary. All the so-called continuous current dynamos really generate—as Lord Kelvin knows well without any reminder from me—alternating currents which are then commuted into continous currents by a costly mechanical device called a commutator affixed to each machine. It is now recognized by electrical engineers that for nine-tenths of ordinary purposes, such as electric lighting and transmission and distribution of power, it is far better as well as cheaper not to add any commutator. By adding it most of the advantages of alternating currents are simply thrown away, and endless troubles are introduced by the sparks at the commuting brushes, to say nothing of other drawbacks. It would be a great pity if the immense influence of Lord Kelvin's opinion were to be used against progress.

SILVANUS P. THOMPSON.

LONDON, Aug. 1, 1895.

GAS AND ELECTRIC HEATING.[1]

BY H. J. DOWSING, M.I.E.E.

AT a recent meeting of the Société Technique de l'Industrie du Gas, of France, M. G. Perthius read a paper on "The Cost of Heating by Electricity." This paper is interesting as showing that electric heating has become of sufficient importance to warrant gas engineers spending their time in denouncing it, and endeaving to prove that electric heating is more costly than gas. Any electrical engineer will acknowledge that a unit of heat produced by electricity at the present charge for current is more costly than that produced by gas, and it is merely flogging a dead horse to endeavor to prove it. The question, however, is not how much does it cost to produce a unit of heat, but *how much of it can you use?* We may, for instance, have any amount of cheap power in the waves of the sea, but how much of it can we employ for practical purposes? It is usually found more profitable to employ steam engine, and pay for every foot-pound produced, rather than to attempt to use wind-power—not only on account of its unreliability, but largely on account of the uneconomical means we have to employ for its utilization. This line of argument should appeal especially to gas engineers, for they entirely depend upon it to prove the economy of gas as a heating agent. M. G. Perthius, in his paper, said that he thought it necessary to throw some light on the subject of the cost of heating by electricity, owing to the sensational articles that were being published, and goes on to state that "whatever might be the source of electricity, its high cost made its practical adoption impossible." Has M. G. Perthius ever heard of electricity produced by water-power? Does he really think that gas, or any other fuel, will produce heat cheaper than can be produced by this means? I know of a large mill driven by water-power where some £700 a year is spent for fuel to maintain the heat necessary for the particular manufacture carried on. The millowners are now about to utilize more water-power, which costs them practically nothing, and warm their mill by electricity. Besides obtaining heat at a very low cost, they will have the advantage of being able to regulate the temperature better than by any other means. In works with ample steam-power, electrical heating can often be produced cheaply, and in large houses with private plants, electric heating can be obtained, especially during the day when it is most required, at as low a cost as by other suitable means. M. G. Perthius bases his comparisons, however, on the very safe grounds of the supply companies' charges, which are well known to be a long way off their lowest point. In order to make a comparison, the writer of the paper takes the cost of heating a ton of water by gas and electricity. Now most people are satisfied to take the cost of heating a pint of water, or at most a gallon, especially as few private houses require *tons* of water heated per day. We are told that with electricity at 5½d. per unit, it would cost 6.3d. to produce heat sufficient to raise a *ton* of water 1° Centigrade, while with gas at 6s. 8d., it would only cost ¼d. It would have been interesting if M. G. Perthius had carried his calculations a little farther, and added the information that with coal at 25s. per ton, the same amount of heat would come to *one twenty-fourth* the cost of gas. With such figures only before us, it would seem surprising that anyone should dream of using *even gas* for heating purposes. One thousand cubic feet of gas at its highest calorfic value (696 units per cubic foot) will produce no more heat units than 55 lbs. of coal. Gas cost, say, 3s., and coal 7d. Why then is gas used for heating at all? *Certainly not because the heat is produced at a cheaper rate*, and this knowledge no doubt accounts for the delay in the gas companies taking up heating and cooking in the first instance. Luckily for the manufacturers of gas stoves (and the gas companies themselves), electric lighting came along and gave the desired impulse. Probably a similar period of incubation is going on in the minds of the directors of electric supply companies at the present time, and some kindly opposition is required to hasten the process. It does seem strange that, with the gas companies' experience before them, smart business men should allow hundreds of horse-power to be dissipated daily without a strenuous effort to dispose of it in a field which is illimitable. Interest on the many thousands of pounds representing the cost of a central station must be earned (together with all costs of working) by the average demand of less than two hours per day. Most companies manage to pay a dividend on this two hours' demand, and if only another two hours' demand could be obtained *at another part of the day*, a double income on the same capital expenditure would be assured. The cost of interest, depreciation, management, and the fixed charges generally, are covered daily by the price per unit charged for lighting. This is acknowledged in Wright's system of charging, and any subsequent demand for current is charged at half rate. An equitable system would be to allow consumers the privilege of using up to their maximum demand during the day at slight extra charge on works cost. A customer having already paid in the price charged per unit for light, a sum representing interest and fixed charges on the amount of machinery necessary to produce the current required, ought not in all fairness to be called upon to pay these charges over again on that day, because he happens to require the current at another time for another purpose. If these matters are taken into consideration, the price charged per unit for "extra" uses would be so low as to, in many cases, approximate the cost of gas.

The reason that more expensive methods of heating than coal may sometimes be used with economy depends, as above stated, as much upon the heat utilized as on the cost per unit to produce. Thus, with our English custom of heating by means of an open fire, 90 per cent. or more of the heat produced from coal is usually wasted, but in the most efficient forms of gas heating apparatus 60 or 70 per cent. may be utilized. This at once shows that the disparity as to cost is not so great as at first sight appears. Add to this the greater convenience and cleanliness, and we see at once why gas may be sometimes used with comparative economy. There is not so great a difference in the cost of heat produced by electricity and gas, as between gas and coal, and when it is remembered that electrical heating apparatus is in many cases far more efficient than either coal or gas, we see that there is a possibility of using it, although the heat unit may be more costly to produce. The electrical system of heating has more advantages over gas than gas over coal. Not only is the electrical system more convenient than gas in being more portable, but it is even more cleanly, for there is an entire absence of combustion. The objectionable smell of gas which in some cases entirely prevents its use is one of the penalties which has to be paid for convenience, but there is no such drawback with electricity. Danger of explosion there is none, and an almost entire absence of danger from fire. Are not these advantages well worth paying for? While the cost of electric heating is more than gas, electricity is steadily replacing the more expensive systems of producing heat as, for instance, the spirit lamp.

With electricity and gas at their present prices, I should recommend no one to use either system for boiling large quantities of water such as are required for household purposes. The only really economical way is to use a separate tubular boiler with coal or coke as fuel. If this system is adopted, all cooking operations can be carried on by electricity with advantage. For cooking purposes far less heat is required than is generally supposed.

1. From the London *Electrical Review*.

In a trial with a gas oven, it was found that out of a total of over 18,000 heat units required in roasting a joint of 8¼ lbs., only 2,203 units were actually used in the food itself, the altogether disproportionate amount of 11,000 heat units being dispersed wastefully. Thus out of a total of 22 cubic feet of gas burned, only 3½ cubic feet were used in cooking the food, or, say, 16 per cent. When it is remembered that the oven is one of the most economical systems of cooking by gas, and more efficient than cooking by coal, it ought not to be a difficult thing for electricity to compete, despite its higher present cost.

Electricity must be compared with gas in the same manner as gas is compared with coal, *i. e.*, its efficiency and advantages must be taken into account. I no more expect that electricity will supersede gas for every heating purpose, than I believe gas will ever supersede coal as a fuel. Each system will have its place, and electricity will be used (as gas is now) where its greater advantages are valued, and not because it is always cheaper to use.

With the extravagant ideas at present abroad as to the amount of heat required for cooking purposes—based, no doubt, on the wasteful systems now in vogue—it may probably surprise many to know that the energy used in a 16 C. P. lamp for one hour would nearly suffice to cook a pound of meat. Of course, the heat would be used, say, in a quarter of an hour, but the energy would be the same.

In criticising the paper above referred to, one of the speakers stated that, in his experience, you could do the cooking by any ordinary system while waiting for the heat to be generated by electricity! This is arrant nonsense. The rate at which the heat is generated depends entirely on the amount of energy used. Heat is generated immediately the current is turned on, and because the makers of electrical cooking apparatus usually find it necessary to make the current small in order to use the existing house wires, it is no reason why a much quicker system should not be employed. Has M. Henri ever seen an electric fry-pan? Within a few seconds it is too hot to touch, and in a minute—or, at most, two minutes—it is ready for use. By what system could the food be cooked in two minutes? M. Delahaye did not think electricity would be used for cooking. Many gas engineers think the same with regard to electric lighting, and I know at least one who is ready to prove to anybody that electricity cannot be made at a price low enough for the electric light to be largely used. Electric heating, as most up-to-date engineers know, is rapidly spreading, and it will soon be a rarity to find a house where electricity is used at all in which at least some form of electric heating apparatus is not to be found. The use of the larger kinds of apparatus will depend very much upon the action of the supply companies, but there are signs that before long electricity will be cheap enough for use in many ways at present out of the question. One instance will show this. Several applications have been received from bakers who wish their ovens fitted for electric heating, but with current at the present charges the cost of working would be prohibitive. What a field for the supply companies! There are thousands of ovens which would require current from *midnight to early morn*. Probably no other outlet of so promising a nature could be found. To sell current when there is not even a day load available seems to be a move in the right direction.

ELECTRIC POWER TRANSMISSION AT FRESNO, CAL.

An interesting long distance power transmission plant is in course of construction at Fresno, Cal., which is unique in more than one particular. The head of water to be used is 1410 feet and the distance of transmission about thirty-five miles. The natural conditions surrounding the installation are extraordinary in themselves. The water for supplying the power is taken from the North Fork of the San Joaquin River at their confluence. The stream of the North Fork runs for several miles down a rocky canyon, forming rapids and cataracts as it runs between the steep mountains. At the head of the rapids a canal will take the water out upon the summit of a high ridge, which it will follow for six miles to a point nearly fifteen hundred feet above the San Joaquin River. Here a reservoir has been constructed with an average depth of ten feet. It covers about eight acres and can be made both larger and deeper, should the demand for power require an extension. Into this reservoir, the water brought along the ridge by the canal will be stored, but it will be used solely as an emergency store. It is calculated that it will hold enough water to drive the machinery for several days, so that should a break occur between the reservoir and the source of supply, the electrical work could continue until the repair was effected.

A pipe line runs directly from the canal a distance of about 4,000 feet, to the power house and the head of water obtained will not be less than 1,410 feet. The pressure at the bottom will be 600 lbs. to the square inch. The lower end of the pipe line is of welded steel pipe, ¾ inch thick, having special steel flanges and special packing at the joints. The amount of water power available is at least 7,000 H. P. at the head above mentioned.

All possible accidents are provided against. Should a break occur near the lower end of the pipe the rush of water would form a vacuum near the upper portion of the pipe and it might collapse under atmospheric pressure. An air valve will be placed near the top to provide against this contingency. The pipes will be made in sections of twenty feet each. At the upper end the metal will be ¼ inch thick and the pipe 24 inches in diameter. It will be fastened to the granite mountain sides by steel cables.

The power station will be located at the bottom of the mountain, and will contain three Pelton water wheels, 58″ in diameter, driven by a single nozzle. The generating plant will consist of three 340 K. W. General Electric Company's three-phase generators. The three-phase system has been selected in this case as the system which will give the highest efficiency of transmission with the lowest cost of copper.

From the point in the North Fork of the San Joaquin River, where the water is taken to the power house at the foot of the mountain, is a distance of about seven miles. From the power house to Fresno, where the electricity will be utilized is about 81¼ miles in a direct line, or 35 miles by the pole line. The line will consist of two circuits of bare copper wire, consisting of six wires strung on poles forty feet high. The current will be delivered to the lines at a pressure of 11,000 volts. From the power house the line will rise to the level of the San Joaquin, cross it and pass through a portion of the Auberry Valley, then rising over the Red Mountain, passing about a mile west of Clovis will continue direct on to Fresno. The first five miles will be over moderately level country, the other thirty through an open and practically level country under ideal conditions for transmission. It is estimated that the power which will be delivered in Fresno at present from the three-phase generators will not be less than 900 H. P.

At the Fresno end the line will be brought into a sub station and there current will be transformed down. From the sub station power will be delivered to all the mills in town, the water works, machine shops, planing mills, laundries, printing presses, elevators, packing houses, etc. It will also be used to drive the street railway system of the city which will require about 800 H. P. In the sub station, two arc dynamos, each of 60 lamps capacity will be driven by an induction motor, the motor being mounted on the same bed plate as, and being direct connected to, the dynamo. Current will be supplied for 4,400 incandescent lamps.

Gas and fuel in the San Joaquin Valley has always brought an extremely high price and this may be considered as the most potent reason for the present installation. It is believed that power can be supplied when the plant is started at about half its present cost; and to the towns around Fresno the privileges of electricity will probably be extended as soon as possible. This plant may easily be considered as taking the lead in the use of a high head of water and the distance over which the power is transmitted.

THE GENERAL ELECTRIC-WESTINGHOUSE DEAL.

A dispatch dated Pittsburgh, Aug. 18, reads as follows: In view of recent reports that the Westinghouse Electric and Manufacturing Company and the General Electric Company were negotiating to combine their companies, Mr. George Westinghouse was seen to-night. He said:

"Three months ago Mr. Twombly, a director of the General Electric Company, had asked me if the Westinghouse Company would be willing to exchange patent licenses upon a basis which would terminate the costly litigation between the two companies. Mr. Twombly was informed that the Westinghouse Company would enter into a general exchange of licenses, and a memorandum was drawn and committees were appointed by the parties to discuss an agreement upon the lines of such memorandum. No meetings of those committees were held, for reasons which only the General Electric officials can explain. It is said to have been due to irreconcilable differences among themselves."

Mr. Westinghouse went on to state that after some delay further offers and negotiations were made and committees were appointed for both companies. These committees met in New York on last Tuesday, Wednesday and Thursday, Charles A. Coffin, President of the General Electric Company, being one of its committee. An agreement was apparently reached, but this was afterward receded from by the General Electric Company. They afterward asked for thirty to sixty days to reconsider the subject. Then the Westinghouse Company declined to go further, believing that the negotiations had already been used in Wall street for stock jobbing purposes. The suggestion made that the companies had agreed upon prices and a division of territory was erroneous, Mr. Westinghouse said.

We have received from Messrs. G. T. Evans & Co. of Pittsburgh, Pa., a very handy Table for Computing Weight, Losses, etc., of Copper Wires. It ought to prove very useful in the hands of wiremen, contractors, etc.

MEETING OF THE ASSOCIATION OF EDISON ILLUMINATING COMPANIES AT DETROIT.

The Eleventh Annual Meeting of the Association of the Edison Illuminating Companies was held in Detroit, August 18, 14, and 15, 1895.

The first session of the Convention was called to order Aug. 18 at 10 a. m. by Mr. C. L. Edgar, President.

The members present were:

New York:—J. W. Lieb, Jr.; Arthur Williams; Luther Stieringer; S. D. Greene; A. D. Page.
Detroit, Mich.:—W. S. Thompson; E. M. Clark; Geo. Wiley; Geo. W. Cato; Geo. Peck; Hoyt Post, Attorney Detroit Company; O. P. Gilbert.
Cincinnati, O.:—John I. Beggs.
Rochester, N. Y.:—Geo. A. Redman.
Brooklyn, N. Y.:—W. S Barstow.
Grand Rapids, Mich.:—Daniel McCoy; A. F. Walker.
Cleveland, O.:—Samuel Scovil; Robt. Lindsay.
Toledo, O.:—Winfield S. Jewell.
Boston, Mass.:—C. L. Edgar.
Chicago, Ill.:—B. E Sunny; Samuel Insull; F Sargent.
Schenectady, N. Y.:—J. R. Lovejoy; W. S. Andrews; Caryl D. Haskins.
Atlanta, Ga.:—H. T. Edgar.
Cumberland, Md.:—J. S. Crider.
Rockford, Ill:—M. A. Beal.
Kansas City, Mo.:—Edwin R. Weeks.
New Bedford, Mass:—Chas. R. Price; Geo. R. Stetson.
Columbus, O.:—A. W. Field.
Hagen, Germany:—Adolph Muller.

After the roll call the Executive Committee represented by its Chairman, Mr. John I. Beggs, made a report recommending the acceptance of the application of three companies for admission, namely, the Edison Light & Power Co., Pottsville, Pa.; the Toledo Electric Co., Toledo, O.; the Sault Ste. Marie Co., Sault Ste. Marie. The companies were admitted to membership.

A report by Mr. A. E. Kennelly, of the Committee on Lightning Protection, Grounding the Neutral in 3-wire Systems, Crosses with High Tension Systems, was accepted and the committee discharged.

Addresses were then made by Mr. S. D. Greene of the General Electric Co., Mr. Samuel Insull of Chicago and Mr. J. I. Beggs of Cincinnati, on "the Relations of the General Electric Co. to Edison Licensee Companies."

After considerable discussion, a paper by Mr. W. L. R. Emmett of the General Electric Co. was read, entitled "Some Comparison between the Direct Current Low Tension System and the Alternating Current and Multiphase System for Central Station Lighting." Mr. Emmett was unavoidably absent and his paper was ordered printed in the minutes. The session then adjourned.

The second session was held at 2 P. M. and the Storage Battery Committee made a report. Discussion followed Mr. Müller, of Hagen, Germany, Mr. C. L. Edgar, and Mr. J. W. Lieb, Jr., gave their experiences. A paper by Messrs. Pierce & Hale was then read by Mr. C. L. Edgar of Boston, entitled "Energy Losses in the Boston Edison Station."

After discussion on this paper, the session adjourned.

The evening was given up to a car ride and visit to Lalla Rookh, the members being the guests of the Detroit Edison Co.

August 14.

The third session was called to order at 10 A. M. A paper by Mr. W. S. Barstow on "Method of Charging for Current for Incandescent Lamps and Motors," provoked much discussion and with Mr. Arthur Williams' paper, "Relation of Company to Customer" occupied the entire morning. The session adjourned at 1 P. M.

The fourth session opened with a discussion by Mr. Beggs, Mr. Greene and Mr. Howell on Incandescent Lamps, Welsbach Light and Acetylene Gas.

A paper by Mr. C. D. Haskins on "Facts in Relation to Mechanical Recording and Chemical Meters" was then read and discussion followed.

The evening was taken up by a drive and lunch on Belle Isle, by courtesy of the Detroit Edison Co. and the General Electric Co.

August 15.

In accordance with past custom, the last day of the Convention was given to entertainments. This took the form of a delightful sail along the river at the invitation of the Detroit Edison Co. who, together with the General Electric Co., received the thanks of the Convention for their past courtesies.

Convention Notes.

The meetings of this Convention were particularly interesting on account of the lengthy and interesting discussions on the various papers. Mr. Edison sent regrets for his inability to attend as he was unable to leave his mining interests at Edison, N. J.

The General Electric Co. presented each member of the Association with a handsome badge representing the fields of a multipolar generator, from the centre of which hung a miniature incandescent lamp. The title of the association, the place of meeting and the date were neatly arranged around the field.

The next Convention will be held in, or in the vicinity of Brooklyn, commencing the second Tuesday in August, 1896, and continuing three days.

Among the non-members who attended the Convention we noticed: Mr. E. W. Little, of the Interior Conduit and Insulation Co., New York; Mr. Geo. A. McKinlock, Central Electric Co., Chicago; Mr. Benj. F. Miles, of the National Carbon Co., Cleveland; Mr. Wallace Franklin, Westinghouse, Church, Kerr & Co., Grand Rapids; Mr. Albert Hoppin, of Allis & Co., Milwaukee; Mr. Martin Insull, of Sargent & Lundy, Chicago; Mr. Charles Wells, of The Electrical Appliance Co., Chicago; Mr. J. S. Crider, of the Washington Carbon Co., Pittsburg, was also present as a delegate.

The only exhibit, if one could call it one, was the Fisher rotary engine in the basement of the Cadillac Hotel. It appeared to be a very practical machine.

REPORTS OF COMPANIES.

BOSTON ELECTRIC LIGHT CO.

The annual report of the Boston Electric Light Company for the year ending June 29, 1895, shows total income, $610,265; operating expenses, $411,449; net, $198,815, less interest on bonds and loans, $31,855, and dividends, $136,000; leave surplus, $30,889; total balance to credit profit and loss, June 29, 1895, $372,611.

GERSON ELEC. MFG. CO.

The Gerson Electrical Manufacturing Company of Philadelphia has made an assignment for the benefit of creditors to George W. Wilgus. The deed is dated July 15, and conveys no real estate.

EDUCATIONAL.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY.

The programme for 1895 of the Massachusetts Institute of Technology gives in detail the course of instruction with a statement of the requirements for admission and a list of the officersr The equipment of the electrical laboratory includes a large numbe of dynamo machines of various patterns, both arc and incandescent, devoted to purposes of instruction. Among these are a 150-light Edison dynamo, and a 9,000 watt, Thomson inclined coil, constant potential dynamo. A 500-light Thomson-Houston alternating current machine, with transformers of various types, also forms a part of the equipment. A 500-light United States direct-current compound dynamo is used for lighting the Engineering Building, and is available for purposes of instruction, as are also several multiphase generators and motors. The laboratory also possesses a number of Thomson-Houston and Edison street railway motors, both bipolar and multipolar.

UNIVERSITY OF NEBRASKA.

The announcement of the course in the Department of Electrical and Steam Engineering in the University of Nebraska for 1895-96, has been received.

The equipment of the electrical laboratory is chosen largely to represent distinct systems of lighting and power. For incandescent lighting: the Edison two-wire, the Edison three-wire, and the Westinghouse high pressure alternate current systems are complete. In addition to these complete systems there is switchboard equipment for the Thomson-Houston alternate current systems, and transformers of the Thomson-Houston, Wagner, Packard, Slattery, and National types. There are also constant pressure dynamos of the Weston and the Donaldson-Macrae designs.

For arc lighting: the Thomson-Houston system representing the open coil, and the Wood and Excelsior systems representing the closed coil types, are complete. Besides this are the T.-H. alternate current system of arc lighting, and the various types of constant direct current arc lamps.

For power and power transmission: the direct and alternate current systems are represented, among which is a Donaldson-Macrae motor plant, the three phase system of the Allgemeine Electricitäts Gesellschaft," and the Scott system of polyphase distribution. The Department is in charge of Prof. R. B. Owens.

ATTEMPTING TO WRECK A STATION AT HARVEY, ILL.

The Chicago *Dispatch* of Aug. 7 says:—An attempt was made last night to damage the electric light plant at Harvey. Emery was poured into all the oil cups and bearings. Fortunately, the cups were all cleaned before starting up the machinery, when the emery was discovered. Had the attempt succeeded Harvey would have been in total darkness for the night.

PERSONAL.

DAVID LEONARD BARNES.

David Leonard Barnes.

THE recent working arrangement concluded between the Westinghouse Co. and the Baldwin Locomotive Works was coupled with the announcement that the joint operations of the two companies would be under the technical supervision of Mr. David Leonard Barnes whose name is well known in the railroad world.

Born in 1858, Mr. Barnes finished his classical education at Brown University, where he graduated with the degree of Master of Arts. Being of a mechanical bent he determined to devote himself to engineering and with that end in view entered the Massachusetts Institute of Technology, following the course in Mechanical Engineering. Shortly after graduation Mr. Barnes entered the drafting room and machine shop of the Rhode Island Locomotive Works, remaining there from 1878 to 1888 and accumulating a vast amount of experience in the construction of railroad rolling stock. In 1883, Mr. Barnes accepted the position of chief draftsman for the New York Locomotive Works, but resigned a year later to accept the position of chief draftsman and mechanical engineer for the Rhode Island Locomotive Works which position he occupied until 1887.

In that year Mr. Barnes opened offices in New York and Chicago, as consulting engineer, making a specialty of railroad rolling stock and operation, elevated and street railways, and electric plants. Mr. Barnes' technical writings have always commanded attention; he is the author of papers on a variety of scientific and technical subjects and of a work on Compound Locomotives. As Mechanical Editor of our excellent contemporary the *Railroad Gazette*, his writings reach a large audience in the railway world. Mr. Barnes is a member of the American Society of Mechanical Engineers, the American Society of Civil Engineers and of other engineering and railroad associations.

MR. LEO DAFT, the well known electrical engineer has removed his offices to Room 408, Stimson Building, Los Angeles, Cal.

MR. C. F. HUTCHINGS, of Pittsburgh, has been appointed Electrical Superintendent of the Wilmington City Railway Company.

MR. WILLIAM C. BENBOW who has for the past six or seven years been with the Engineering and Mining Departments of the Thomson-Houston and General Electric Companies has recently resigned his position to assume the management of the mines of the Cambridge and Guernsey Consolidated Fuel Co., at Cambridge, Ohio.

MR. HARRY B. COX, of Hartford, has returned from Europe, where he has successfully disposed of the English and European patents on his thermo-electric apparatus. Mr. Cox reports that he has had over eleven hundred inquiries directly from the recent illustrated article in the columns of THE ELECTRICAL ENGINEER, and that his device elicited the most intense interest among English electricians.

LETTERS TO THE EDITOR.

THE RELATIVE ECONOMY OF CONSTANT POTENTIAL AND CONSTANT CURRENT ARC LIGHTING.

I HAVE been several times on the point of setting on foot a discussion, so opportunely introduced by Mr. W. N. Stewart in your issue of August 7, as to the relative economy of constant potential and constant current arc lighting systems. Now that the question has been seriously raised by Mr. Stewart, and has elicited a reply from Mr. E. R. Knowles in your issue of the 14th inst., the following notes, which I hope to substantiate at some future time by the figures themselves, may prove of interest.

In June, 1894, the Edison Electric Illuminating Co. of Brooklyn began lighting the streets on an extensive scale by means of constant potential arcs run from their underground mains. As this plan was more or less of an experiment, it was to be expected that the operating expenses of the first six months would be far in excess of the normal; and that a comparison between this new system and the older, or constant current, system would therefore be unfair to the former. Frequent inspections of the machinery, appliances and personnel of the various companies operating in Brooklyn have gradually led me to the belief that the constant potential arc lamp can hold its own against its older rival.

On July 1, 1895, the Citizens' Electric Illuminating Company, operating constant current arc lamps, passed under the control of the Edison Company. I at once endeavored to obtain comparative figures on economy, but without success, since totally different methods of account keeping were employed, and it was necessary to reduce to a common basis of comparison one system all underground with ornamental iron bracketed poles and serving incandescent lamps as well, and another system nearly all overhead with wooden poles and mast arms and serving arc lamps only. However, the subject has received considerable attention at the hands of the Edison authorities and myself; and with the promised assistance of the former there may be some figures forthcoming as soon as the operation of the two systems under one management and one system of bookkeeping will furnish the data.

Even should these figures prove, as I think probable, that the economy of constant potential arc lighting on a mixed circuit (arc, incandescent and motor) is greater than that of constant current arc lighting on a purely arc circuit, thus upholding Mr. Stewart's argument, the points submitted by this gentlemen have a still wider application, and may be used in comparing a pure, constant potential with a pure constant current arc system.

As Mr. Knowles intimates, it is doubtful whether anyone would seriously advocate the use of a pure constant potential arc system; and yet, five years ago the Siemens & Halske people not only advocated, but actually installed, such a system in Tokyo, Japan, to supply quite an extended area. In this instance the dead resistance consisted of a carefully proportioned lead from one lamp to its mate. On our ordinary constant potential mixed circuits the dead resistance for each pair of lamps takes up from thirty-five to forty volts. How much of this is essential for the elasticity of the circuit? Can we not cut this resistance down so as to make a constant potential pure arc lighting system, with its improved machinery, smaller floor space, decreased attendance and absence of belting and countershafting, a commercially desirable installation? Is there not a field for such a system in the territory now covered by the constant current system, similar to that occupied by the low tension system in the incandescent lighting industry? With no lamps or motors to bother us, we can make the voltage of our circuits practically what we please, and the dead resistance is no longer required to *take up voltage*, but merely to give elasticity.

The old, old story of the greater economy of the constant current system has lost its charm—except it be accompanied by figures. We have learned this story, just as we have learned our politics and religion, by being so taught when we were young. Now it is time either to quit believing, or to know *why* we believe. Will those who know please tell us?

H. S. WYNKOOP, M. E.

BROOKLYN, August 14, 1895.

[THE subject here under discussion is one of vital importance in electric light economy and we will be glad to give space to further contributions on it. EDS. E. E.]

THE REGULATION OF THE POMONA PLANT.

IN the *paper* on the "Pomona Plant," read before the Amer. Inst. of Elec. Engrs., by Mr. G. H. Winslow, the writer makes some statements in regard to the regulation, here, which are hardly up to date.

There is practically no hand regulation used in this plant, as, owing to some more careful adjustments, made some time ago, there is no "see-sawing." All the *hand* work we do, is making slight changes in the *field* charge, to compensate the difference in speed between electrical changes of load and the slower action of the water wheels.

JOHN E. ADAMSON, Electrical Engineer,
San Antonio, Cal., Light and Power Company.

SAN ANTONIO, CAL., Aug. 5, 1895.

LIGHTNING DRIVING ELECTRIC CARS.

REFERRING to your article headed "Can Lightning Run Trolley Cars?" in the issue of August 7, I would suggest that in the instance mentioned by the Connecticut reporter the lightning traveling along the conductor entered the motor by arcing across the spaces between contacts in the controller box, actuating the armature through the contact which first throws the current into the armature, thus causing the car to move. It is quite probable that there were other paths of escape along the line for the lightning discharge which prevented the armature being burned out.

SCIENTIFIC USES OF LIQUID AIR.[1]—I.

BY PROF. J. DEWAR, F. R. S.

WHEN Faraday was working on liquid gases in this Institution about 1823, with such means as were then at his command, his inquiry was limited to the determination of the specific gravities and vapor pressures of such bodies. Twenty years later, by the use of solid carbonic acid, the greatest cold then possible was obtained, and Faraday made admirable use of Thilorier's new cooling agent to extend his early investigations. Just as liquid carbonic acid produced in glass tubes was of no use as an agent for effecting the liquefaction of more resisting gaseous matters, until it could be manipulated in the solid state, so liquid air, until it could be handled, stored and used in open vessels, like any ordinary liquid, could not be said to possess scientific uses in any wide sense. Such operations become easy when double-walled vacuum vessels (such as were described in a former lecture) are employed in the conduct of experiments where substances boiling at very low temperatures have to be manipulated. The chief scientific use of liquid air consists in the facilities it gives for the study of the properties of matter at temperatures approaching the zero of absolute temperature. In this lecture the expression liquid air may mean either oxygen or air. Where a constant temperature is required oxygen is used. Liquid air made on the large scale may contain after it is collected in open vacuum vessels, as much as 50 per cent. of oxygen. Such a liquid boils between —192°C. and —182°C., and the longer it is stored the nearer it comes to —182°C., or the boiling point of pure oxygen. For a number of experiments of a qualitative character, whether it is liquid air or oxygen that is used makes no difference. In many of the experiments to be recorded, liquid oxygen made from the evaporation of liquid air was employed. In pursuing this subject in consort with Prof. Fleming,[2] a long series of experiments, involving the use of large supplies of liquid oxygen, have been carried out on the electric resistance of metals and alloys, and the results warrant the conclusion that at the zero of absolute temperature all the pure metals would be perfect conductors of electricity. Under such conditions a current of electricity started in a pure metallic circuit would develop no heat, and therefore undergo no dissipation. Similarly, we infer there would be no Peltier effect at the zero. In other words, the passage of electricity from one metal to another would take place without evolution or absorption of heat.

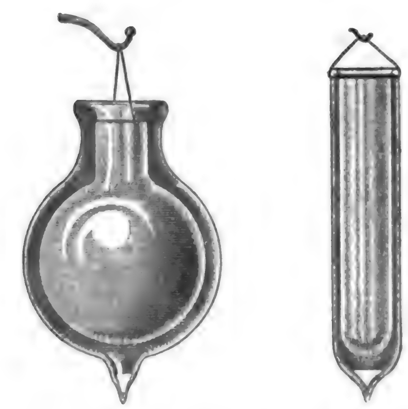
Further investigation, along with Prof. Liveing,[3] on the refractive index of liquid nitrogen and air, has led to the conclusion that the refractive indices of nitrogen and air are respectively for the D-ray, 1.2053 and 1.2062. In these determinations, instead of using the prisms, we have employed the method of Terguem and Trannim, which consists in suspending in the liquid two plates of glass with a thin layer of air between them, and measuring the angle of incidence at which the chosen ray suffers total reflection at the surface of the air. As all the vacuum vessels are either spherical or cylindrical in form, when filled with liquid they act as lenses which are irregular and full of striations. Further, small bubbles of gas being given off in the liquid rendered any image indistinct when viewed with a telescope. In order to avoid the necessity of observing any image through the liquid, it was used simply as a lens to concentrate the light observed on the slit of a spectroscope. Under such conditions the observations were easily executed, and the results satisfactory.

For some time a series of observations on the thermal opacity of liquid oxygen and nitrogen have been projected. It is, however, exceedingly difficult to experiment in such a way as to eliminate the absorbing action of the glass vessels, and as the use of rock salt is impracticable, the absorption of heat of low refrangibility remains for the present undetermined. It is possible, however, to use the glass vacuum vessels to determine approximately the relative thermal transparency for heat of high refrangibility, such as is radiated by a colza lamp. The following results represent the heat transmitted through the same vacuum vessels filled with different liquids, taking chloroform as the unit for comparison and correcting for differences of refractive index :—

Chloroform	1.0
Carbon bisulphide	1.6
Liquid oxygen	0.9
Liquid nitrous oxide	0.93
Liquid ethylene	0.60
Ether	0.50

From this result it follows that liquid oxygen is nearly as transparent to high temperature heat radiation as chloroform, which is one of the most transparent liquids next to carbon bisulphide. Liquid ethylene is much more opaque. These results must, however, be considered only as an approximation to the truth, and as generally confirmatory of the inferences Tyndall drew as to the relation between gases and liquids as absorbents of radiant heat.

Instead of silvering the interior and exterior of the vacuum vessels, it is found convenient when using mercury vacua to leave a little excess of liquid mercury, in order that the act of filling the inner vessel with liquid air should cause a fine silvery deposit of the metal over the exterior surface of the inner vessel. In such a vessel liquid air or oxygen shows no signs of ebullition, the surface remains as quiet and still as if it was ordinary water. The supply of heat is cut down to less than 4 per cent. of what it is without exhaustion and silvering in good vacuum vessels. The result is that volatile liquids can be kept 30 times longer. Such vessels do not, however, maintain indefinitely the high standard of heat isolation they possess the first time they are used. After repeated use all vacuum vessels employed in the storage and manipulation of liquid air deteriorate. Illustrations of the appearance of such vessels are given in Figs. 1 and 2. The rapidity with which a space is saturated



FIGS. 1 AND 2.—VACUUM VESSELS FOR STORAGE OF LIQUID AIR.

with mercury vapor (which we know exerts a pressure of about one-millionth of an atmosphere) is easily proved by simply filling a barometer in the usual way, and then instantly applying a sponge of liquid air to a portion of the glass surface of the Torricellian vacuum space, when a mercury mirror immediately deposits. It is important to know the amount of mercury deposited from a saturated atmosphere which is maintained (containing excess of liquid mercury) at the ordinary temperature, the condensation taking place when liquid air or oxygen is discharged into a vessel surrounded by such a Torricellian vacuum. If the deposit on the cooled bulb is allowed to take place for a given time, the outer vessel can then be broken and the amount of mercury which coated the bulb ascertained by by weighing. Knowing the surface of the cooled bulb, the amount deposited per unit of area can be calculated. In this way it was found that in ten minutes two milligrammes of mercury per square centimetre of surface was deposited. Considering that one-tenth of a milligramme of mercury in the form of saturated vapor at the ordinary temperature corresponds to the volume of 1 litre, this proves that the equivalent weight of 20 litres had been condensed in the space of ten minutes. This plan of cooling a portion of the surface of a vessel by the application of a liquid air sponge, enables us to test our conclusions as to the amount of matter present in certain vacua.

SOCIETY AND CLUB NOTES.

SOCIETY OF THE U. S. MILITARY TELEGRAPH CORPS AND THE OLD TIME TELEGRAPHERS AND HISTORICAL ASSOCIATION.

THE Fifteenth Annual Reunion of these two societies will take place in New York, Sept. 11, 12 and 13, with headquarters at the Broadway Central Hotel. The programme of arrangements includes elaborate provisions for the entertainment of the members, including an entertainment at Chickering Hall, an ocean excursion to Long Branch, and general sight seeing. It is the desire of the Committee of Arrangements that every member of the Societies who can arrange to do so, should be present with his family at the Fifteenth Reunion. Notices of intention to attend the meeting should be sent to Mr. C. P. Bruch, 253 Broadway, Chairman Committee on Reception; for transportation rates, to Mr. J. F. Shorey, 195 Broadway; and for hotel accommodations and rates, to Mr. M. W. Rayens, 195 Broadway.

MR. J. F. BLAUVELT, of the New England Butt Co., of Providence, was a caller at this office this week and reported business in braiding machines to be steadily, if somewhat slowly, on the increase.

CONTENTS.

THE "EXPRESS" TELEPHONE SWITCHBOARD.

ELSEWHERE in this issue we publish a description of the telephone switchboard designed by Messrs. Sabin and Hampton, of San Francisco, and known as the "Express" board. It is claimed that with the new system more efficient service can be given than is possible with the best type of "multiple" switchboard now in use. Inasmuch as the multiple switchboard utilizes the principle held by many to be the best possible to secure rapidity of operation, the claim that with a totally different construction superior results can be accomplished is one demanding serious consideration. One of the advantages claimed for the new switchboard is said to be its lesser cost of installation as compared with the multiple board. We can readily believe such a statement, as the latter involves a repetition of working parts in an extraordinary degree, while in the other there is no such repetition. But in considering the matter of cost it should be remembered that the time element in telephony is more important than economy of equipment. The telephone, to be of any use at all, must be a time saver, and no system, however cheap it may be, can displace another unless it can show itself at least equal to existing apparatus in the saving of time. A leading feature of the Sabin-Hampton system is that the labor of making connections is divided into three parts performed by different operators. The difficulty of getting operators to act in concert has always been recognized, and the experience gained in the working of an analogous though now obsolete type of switchboard has doubtless influenced inventors against the division of labor in telephone operating. In the system we describe, an elaborate arrangement of visual signals has been introduced, with the result, it is claimed, of securing concerted and prompt action on the part of the operators. The visual signals referred to form the most interesting part of the apparatus, and as the efficiency of the service entirely depends on their satisfactory action, their mode of working will repay close study.

THE ALTERNATING CURRENT IN RAILWAY WORK.

MUCH of the time of electro-technical bodies both here and abroad was formerly taken up with discussions on the relative advantages of the continuous and alternating current. The continuous current having been first in the field its advocates siezed every opportunity to point out how the alternating current was unsuited to all applications of power, and that such a system was practically debarred from enjoying the benefits of a large part of the earning capacity of a station. The introduction of the polyphase system has done perhaps more than anything else to bring about a parity between the two types of current, and though at present employed more generally for long distance transmission work, the number of central stations adopting the polyphase system is gradually but surely increasing. At the same time we notice several instances in which the polyphase current has been applied in railway work, among others at Sacramento, Cal., and at Lowell, N. H. In these instances it is true the alternating current is being converted to the continuous by rotary converters, but it shows a growing application of a method designed to avoid the use of heavy feeders. This application of the poly-

phase current seems to be but an opening wedge to a more direct application of the alternating current to the driving of the car itself. We know as a matter of fact that experiments with this end in view are being carried out in several quarters, and that while the results are not yet such as to warrant the offering of the system as a substitute for the continuous current, enough has been learned to afford encouragement for further experiments in the same direction. As to the type of alternating current to be used, whether single, two or three-phase, other conditions than mere efficiency and economy will have to be considered and more particularly that of the number of working conductors necessary. Both the two and three phase system would require at least two overhead conductors in addition to the ground return and this will no doubt militate against the application of either of these systems. We need only recall the strenuous opposition of the street railway companies to the adoption of the double trolley system which the telephone companies tried to force upon them in the early days of electric railroading, and which they even now spasmodically bring forward. This objection of course would not lie where the conductor system were placed underground. But with the general conditions of street railway traffic before us it will require most extraordinary conditions and advantages to induce railway companies to operate more than a single overhead wire and such being the case the single phase alternating current, for the present, seems the only one available, for general city traffic at least. The single-phase synchronous motor would therefore find its most immediate application and would call for special gearing to adapt it to the needs of the varying speeds of street car traffic. A number of such gears, among them those of the hydraulic type, are available and will probably find an early application to this work.

THREE CENT CAR FARES.

The trolley has won its way to a position of incalculable usefulness through a period of abuse without equal in its virulence, falseness and stupidity, and is now at the point where it is beginning to accomplish various utilities that its friends hardly dreamed of in the early days. People are now expecting impossibilities of it, and the press that so lately was full of scorn and contumely is now about as full of wild predictions of what the trolley is going to do for rural communities, and for high speed over long roads. We note another topic of recent origin upon which a great deal will shortly be heard, namely three cent car fares, which promise at no distant date to be in some places a further genuine benefit accruing from the adoption of electricity as a motive power. There can be no question that the trolley has brought a reduction of fare well within the range of practical politics, for in Detroit we already find the fine new Peck-Everett system selling tickets at 8 for 25 cents; while in a few other cities agitation or negotiation has already begun. Many roads would, we know, be seriously, if not fatally crippled at present by a fare less than 5 cents; but there are a number of plans that may become feasible, ensuring economy to the passenger without lessening the necessary income of the company. We are altogether too fond in America of running everything on the flat rate principle, which, satisfactory as it may be for rough and ready times, is altogether too crude for an age of science and a close adjustment of social economics and conditions. The rider who pays 5 cents for 2 cents of brief service has right in his complaint. It will be several years, probably, before the 3-cent unit becomes universal, but the tendency has already begun to manifest itself, and foresight must determine what is to be done about it. Not only in major, but in minor, aspects, the subject involves important considerations and careful calculation as to the amount of service that a road can honestly and legitimately give for so small a fare. The extent to which such a reduction might foster the habit of riding is also worthy of study, and no harm can be done by ascertaining the amount of short riding that can be worked up on minimum fares.

OFFICIAL EDICTS AS TO FENDERS AND HEATERS.

The Massachusetts Railway Commission has lately given the street car lines within its jurisdiction plenty of food for thought as well as an opportunity for work and expenditure by ordering a wholesale equipment of all cars with fenders and electric heaters. Both edicts might, it seems to us, be questioned on the score of propriety, perhaps even on that of legality; but they are a good sign of the times. We confess to having very little faith in the majority of the fenders now on the market, but such an order as this should be the means of bringing about a sharp and severe testing and analyzing of the different and multitudinous appliances, and should hold up the best in a strong light. Our regret is that the commission does not show itself equally emphatic in regard to brakes. Street cars need just as efficient brakes as steam cars do; and the air brake is none too good for them.

As for electric car heaters, we can only hope again that the step is not premature; and we venture to think that here again is a direct incentive to improvement, economy and perfection. Other States will certainly fall in line, and the demand anyhow this fall will be enormous. We are a little curious to see the effect on the power-house, for the change requires the generation of no small amount of current, with a corresponding increase in the dynamo and the engine capacity. There should be some very interesting records soon for statisticians to dissect. Whatever be the economy, there can be no doubt as to the gain in the cleanliness and healthfulness of the cars by the adoption of the new method.

TWENTY-FIVE YEARS OF EXISTENCE.

THE mortality of industrial concerns was long since proved to have a high rate, to which as elements of disappearance in late years may be added the practice of consolidation and the prevalence of trusts. It is a really noteworthy event to find a concern celebrating its quarter century, and we hasten to offer our hearty congratulations to the American Electrical Works upon such an anniversary, in the celebration of which a host of friends joined it last week. The electrical field has always been kaleidoscopic in its business changes, and there are not a great many that have lived through the growth of the telegraph, the birth of the telephone, the dawn of the electric light, and the rise of electric power. The insulated wire manufacturers have exhibited greater vitality than almost any other group, which can be readily understood in view of the fundamental nature of their product in all of the electrical arts,—and such names as Day's Kerite and Bishop recall at once the pioneer work that is now in reality more remote in years than in other qualities of present significance. When a house has lived through a quarter of a century and is in touch and sympathy with the times it has given no mean pledge of its ability to endure and prosper through further terms, and this happy lot will be desired by all of us for Messrs. Phillips and Sawyer and their associates, as well as for all other well-doers in this noble field of electrical industries and arts.

1870—1895.

TWENTY-FIFTH ANNIVERSARY AND SEVENTEENTH ANNUAL CLAMBAKE OF THE AMERICAN ELECTRICAL WORKS.

Eugene F. Phillips.

THERE was no need for any one to consult the weather prophets on last Saturday, August 17, for, as every one in the electrical business well knew, it was the day set apart for the annual bake given by the American Electrical Works to the electrical fraternity, and "Phillips' weather" as it has come to be known, was sure to ensue, and that meant fair skies, a glorious, warm sun, and cool, refreshing and inspiriting breezes from Narragansett Bay. These annual clam bakes are now familiar to most electricians, from Maine to California, are always enjoyed and looked forward to by busy city business men, who throw off their dignity once a year, and go in for a merry, light hearted time, just as they did years and years ago before they had gotten out of their teens.

This year, however, there was an added interest in the occasion, as the Summer of 1895 marked the twenty-fifth anniversary of the career of Mr. Eugene F. Phillips, the president of the American Electrical Works, in the manufacture of insulated wire for electrical purposes, and it might be truthfully stated, the twenty-fifth anniversary of the great electrical industry, which in 1870 was just about developing that potential force, which has since made it one of the leading industries of the world.

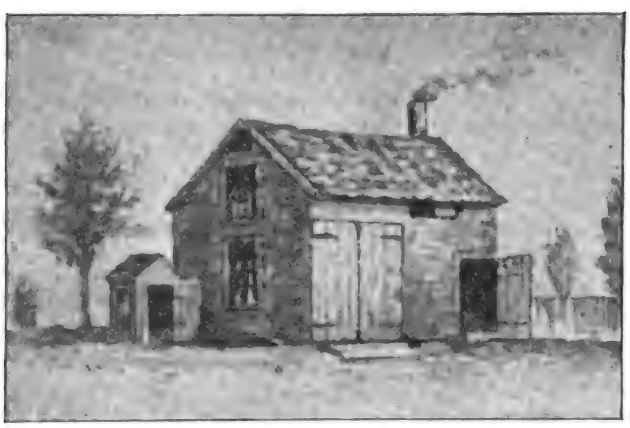
W. A. Hathaway.

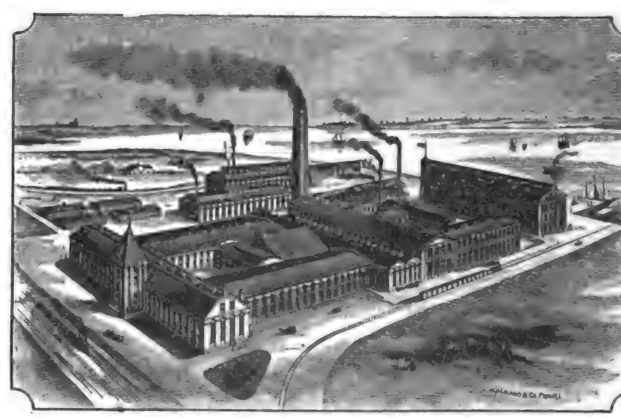
Such being the case we think a short history of the development of the American Electrical Works will be found interesting at this time. Previous to the year 1870, Mr. Phillips was associated as treasurer with the Atlantic Tubing Co. of Providence, a company which was engaged in the manufacture of flexible gas tubing. At that time the question of covering electric wire occurred to him, and as his company would not experiment in this new line, Mr. Phillips commenced to manufacture insulated wire in the barn of his own house, situated on Chestnut street, taking his power by means of a shaft from a jeweller's shop in the vicinity. His experiments in this line were successful, the business grew apace, and in 1874, commodious wooden buildings were built on Stewart street, and the manufacture of insulated wires became an established business. Soon it was necessary to increase the capacity, and the handsome brick buildings on Stewart street were erected in 1882, in which year also the American Electrical Works were incorporated, and as the business grew larger other buildings were erected until a large factory stood very near the site of the old barn where the business was begun in 1870.

W. H. Sawyer.

As new departments were added, however, to keep pace with the rapidly growing electrical industry, and larger cables became necessary, it became evident that even larger quarters were necessary, and in 1893, the site of the old Richmond Paper Works was secured at Phillipsdale, R. I., a little village named after Mr. Phillips, about two miles up the Pawtucket River, from Providence. The new factory contains about 2½ acres of floor space, and is surrounded by about 28 acres of ground. The company has a boarding house for its employees, a grocery store, and practically maintains the whole village. About 700 hands out of a capacity of about 1,000 are at present employed, and work is being carried on 20 hours out of the 24. The capital of the company is now $750,000, and they use about 3 car loads or about 75,000 pounds of copper bars a day.

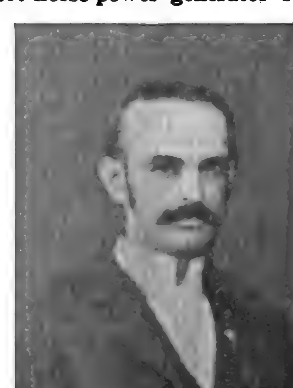
The most important innovation at the new factory, was the introduction of rolling and drawing mills, and now the company handles the copper just as it comes from the Lake in ingots, rolling it first into long rods about ⅜ of an inch in diameter, and then drawing it to any desired size from No. 0000 solid down to wires as small as one and one-half one-thousandths of an inch,—about half the diameter of the human hair. The factory is lighted by three 250-light incandescent dynamos, and one 85 arc light machine, and has a 250 horse-power generator for furnishing power to different parts of the factory.





1870. THE AMERICAN ELECTRICAL WORKS. 1895.

Mr. Phillips has been ably assisted since January, 1878, by Mr. W. H. Sawyer. This gentleman started his electrical career at the age of 14, and came prominently to the notice of electricians at the Centennial Exhibition, where he had charge of the electrical construction under Mr. W. J. Phillips. Mr. Sawyer was also one of the originators of the American District Telegraph Co., was at one time superintendent of the Gold & Stock Co. and American District Co., of New York, and was afterwards superintendent of the American District Telegraph Co., of Philadelphia. In 1878 he brought his practical



P. C. Ackerman.

electrical experience to the assistance of Mr. Phillips, and has ever since had charge of the practical manufacturing and the electrical department.

Mr. W. A. Hathaway joined the American Electrical Works in February, 1888, and Mr. C. R. Remington, Jr., in April, 1888. The history of these gentlemen is synonymous with the growth of the company. They entered the company as practically their first business experience, and have grown up with it, gaining in good will and popularity amongst the electrical trade, until to-day it would be difficult to find two men better known or more heartily admired and liked, in the electrical trade.

Mr. P. C. Ackerman, in charge of the company's New York office, dates his connection with the wire trade back for 12 years, of which 9 have been devoted to the service of the American Electrical Works. Frequent trips from Maine to California have, barring the staff of the Company, made Mr. Ackerman perhaps the best known man connected with it. Since the establishment of the Western office, at Chicago, under Mr. F. E. Donohoe, Mr. Ackerman has not travelled west of Chicago, but is popularly known to the trade in the Eastern States. His office is at 10 Cortlandt St., New York, and his figure is a familiar one in the electrical centre of the city.

As to the Clambake, what more can we say than we have said in previous years? About 200 guests accepted Mr. Phillips' kind invitation and partook of his royal hospitality at Haute Rive Club, and joined in the usual festivities, playing base ball, foot ball, striking with the heavy hammer, lifting heavy weights, and in all other conceivable ways, which men so well know when they are freed for a day from the cares of business. The base ball match was a tie, of course; that is the only safe way on these occasions, or the umpire's lot would otherwise, in the language of Gilbert, be "not a happy one." The usual electric athletes distinguished themselves to their own entire satisfaction, and records for all kinds of feats, not the least being the number of clams disposed of, were as easily beaten as in former years.

The after dinnner speeches were particularly happy. Mr. Thos. D. Lockwood, acted as toastmaster, though as in previous years, speechmakers confined themselves, or rather unconfined themselves, to subjects totally distinct from the toast to which they were supposed to be replying. That seems to have got to be a point of etiquette, on these occasions, which must not be transgressed. One excellent innovation desires mention and was introduced by Mr. Phillips, and that was the feeling way in which he referred to many who had passed away to their long rest within the past year or two, and whose smiling faces were sadly missed. It showed good feeling, and as one speaker said, it was pleasant to think that in after years when one might be called away to the happy hunting grounds—I was going to say clam fields,—their memory might be recalled on such occasions, and a toast quaffed to their memory. Mr. Phillips, proposed the toast of "Dear Departed Friends;" Mr. Ralph Pope replied to the toast of the "Telegraphers;" Mr. Lockwood responded to the "Telephone;" Mr. W. S. Key in an eloquent address responded for the "Electrical Press;" Mr. C. S. Sergeant for "Electric Power Transmission;" Capt. Wm. Brophy for "The Electric Light;" and then Mr. Lockwood proposed Mr. Phillips and the members of the American Electrical Works as "Jolly Good Fellows." Mr. Phillips in reply to the toast stated that he had given great thought to the development of the manufacture of electric wire, and had remained up at least one night thinking out many profound problems, and called upon his son who was present to stand up in corroboration of his father's statements. This the young man did, amidst the loud applause and laughter of the guests, after which they dispersed to wander about the grounds till it was time to again think of going home.

An unusually handsome souvenir was distributed this year, which was much prized by the recipients. It represented in silver, a basket of the succulent Rhode Island clam, full to the brim, and capped with a ripe ear of yellow corn. It makes a handsome paper weight, and we offer our sympathies to those who were not there to get one. This account cannot be concluded better than by the well chosen words on the back of the menu of this year:

"True philosophers, methinks,
Who love all sorts of natural beauties,
Should love good victuals and good drinks."

Thackeray.

"JUST THE THING FOR PRACTICAL MEN."

Mr. H. W. Jeamin, superintendent of the Jonesboro, Ark., Power Co. writes: You will find enclosed 60 cents for which please send me by return mail one of your morocco filing cases. I cannot express my appreciation in words for your enterprise in getting up those data sheets. It seems just the thing for practical men (such as myself), who are struggling under small salary to get a foothold in the field of electricity, who start in without a technical education, and learn what they can by dint of hard study and the expenditure of about all their means. I have found it very hard work and expensive to collect such data pertaining to my business in all of its details; viz., electric lighting. I take THE ELECTRICAL ENGINEER as well as several other technical papers. THE ELECTRICAL ENGINEER is my favorite, and I will always speak a word of praise for it whenever the opportunity offers.

THE CONSCIENTIOUS CLAIMS OF COLUMBUS, GEORGIA.

COLUMBUS, GEORGIA, is making an earnest and "conscientious" bid for the attention of the many visitors who will be attracted southward by the Atlanta Exposition, some of whom will keep a shrewd eye on the commercial possibilities of the New South. We have received a condensed folder, which is intended to give any one seeking a location in the South such information as he might desire. It gives the special advantages of Columbus, Ga., as a cotton manufacturing centre, and the inducements offered to those desiring to establish other industries there.

ELECTRICAL ACTIVITY IN CALIFORNIA.

The Oakland, Cal. *Enquirer* says: It is one sign of the times when an electric plant to cost $38,000 is contracted for in San Francisco. That will be the cost of the electric outfit of the Parrott building on Market street. According to Fresno advices, the dam across the San Joaquin river near Millerton, twenty-six miles from Fresno, will be completed during the present month and the machinery and appliances for the new electric power plant are said to be ready to put in. Poles are going up between Grass Valley and Nevada City for the Nevada Electric Power Company, and the Gold Hill mine will be operated by electricity. The Power Development Company of San Francisco, of which Charles Webb Howard is the president, expects to furnish at least 10,000 horse power from the water of the Kern river canyon, thirteen miles northeast of Bakersfield.

THE BALDWIN-WESTINGHOUSE PLANS.

So much misinformation, says the *Railroad Gazette*, has been published as to the purpose of the Baldwin-Westinghouse people that it may be worth while to say a little more explicitly what we have already said as to precisely what they intend to do. The first work to be done is to get up a set of designs for standard equipment. This will include motor trucks for light and for heavy service. Whether these trucks will be put under cars which will carry passengers, or baggage, or freight, or mere ballast, to give adhesion weight, will depend entirely upon the conditions in which they are used. This is a mere detail of construction. It is quite likely that in some cases the platforms under which such trucks are put will be covered over, to give the vehicle something of the appearance of electric locomotives, such as have already been built. It is quite possible, also, that this will not be done. The essential thing is to get up designs for trucks to carry the motors, which will be up to the best locomotive practice in economy of construction, safety of operation, and ease and economy of repair. When this equipment has been designed, doubtless one, or two, or three motor trucks will be built, and will be used experimentally. The companies have many requests for plans and estimates for electrical equipment of existing lines and of projected lines, and it is highly likely that they will have all they can do as soon as their standard equipment is thoroughly worked out. We have not learned, however, that they have been asked for designs for equipment for main lines of railroad, and feel sure that they would not encourage such an experiment.

THREE-PHASE APPARATUS IN POWDER MILLS.

The American Powder Co., at South Acton, Mass., have contracted for the building of a three-phase power plant, consisting of two 75 K. W. 550 volt generators, and eight 20 H. P., one 10 H. P. and three 5 H. P. induction motors all wound for similar voltage. The generators are to be driven by a combination of steam and water power. Water wheels driving from 100 to 150 H. P., and an engine supplying whatever may be required in excess of the capacity of the wheels up to 150 or 200 H. P. The motors will be placed at distances of about 800 feet to 2,600 feet from the generators, the line being practically continuous in one direction. The majority will be placed in a group at about 800 to 1,200 feet from the generator.

The motors will be housed in small brick buildings built for and adjacent to each powder mill, there being in no case more than one motor to a mill. These mills are all quite small, as each step in the powder making process is carried on in a different mill. The main shafting of each mill extends outside the mill proper and to this shafting the motors will be belted, running at an average speed of 110 to 120 revolutions. It will thus be seen that there is no motion in any mill except that necessary for the manufacture of powder. The equipment of these mills is directly due to the success which has attended the operation of two other mills of this company located in the West, which are operated by continuous motors and generators.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUG. 13, 1895.

Accumulators:—

Support for Electrical Batteries Used in Vehicles, T. Frogatt, London, Eng., 544,480. Filed May 1, 1895.

Alarms and Signals:—

Relay, T. B. Dixon, Henderson, Ky., 544,351. Filed Nov. 17, 1893.
Details of construction. Used in connection with a railway signal track instrument.

Thermostatic Instrument, M. Martin, Malden, Mass, 544,363. Filed June 5, 1893.
Details of construction, to keep dust from terminals.

Electromagnetic Signal, C. E. Scribner, Chicago, Ill., 544,387. Filed Jan. 8, 1895.
Two strips of soft iron placed within the centre of a solenoid are repelled at their ends when the solenoid is energised.

Conductors, Conduits and Insulators:—

Manufacture of Electric Cables, W. R. Patterson, Chicago, Ill., 544,372. Filed Aug. 24, 1891.
A machine for winding paper tape loosely on the wire.

Cleat for Holding Electric Wires, E. W. Buffington, Fall River, Mass., 544,501. Filed Mch. 15, 1895.

Apparatus for Insulating Wire, T. N. Hallanger, Chicago, Ill., 544,530. Filed Nov. 14, 1891.
Machine for carrying out process described in patent below.

Insulated Electric Conductors, T. N. Hallanger, Chicago, Ill., 544,531. Filed Feb. 18, 1893.
Each conductor is surrounded by a spirally wound tube, leaving an air space.

Dynamos and Motors:—

Commutator Connection for Dynamo Electric Machines, H. H. Wait, Chicago, Ill., 544,339. Filed Mch. 1, 1895.

Commutator Brush Holder, G. J. Junker, Mt. Vernon, Ill., 544,358. Filed Nov. 9, 1894.

Construction and Method of Operating Dynamo Electric Machines, F. H. Loveridge, Coldwater, Mich., 544,361. Filed Aug. 2, 1894.
The machine is adapted to deliver currents of various potentials simultaneously from the same commutator.

Winding for Dynamo Electric Machines or Motors, E. Thomson, Swampscott, Mass., 544,396. Filed Jan. 27, 1894.
A laminated core provided with projecting iron extensions between the coils, and having each single coil or circuit which generates or utilizes an alternating impulse, divided and interspersed between projections that occupy different positions around the structure.

Combination Dynamo, E. P. Warner, Chicago, Ill., 544,633. Filed Feb. 24, 1890.
A switch adapted to short circuit a portion of the field magnet coils to reduce the field strength, whereby the dynamo may be readily converted from a full arc to a half arc machine.

Electrometallurgy:—

Process of and Apparatus for Extracting Ores by Electrolysis, E. W. Clark, Butte, Mont., 544,610. Filed Nov. 5, 1894.
Places the positive and negative electrodes in separate chambers, one of which is a separating and the other an amalgamating chamber, provided with a channel or passage between them, within which channel is interposed a screen or filter, whereby the chlorine gas is generated in one compartment or chamber and the hydrogen gas and hydrate of soda in another.

Lamps and Appurtenances:—

Support for Incandescent Lights, C. A. Carmany, Middletown, Pa., 544,502. Filed Sept 8, 1894.

Electric Arc Lamp, R. H. Cunningham, Richmond, Va., 544,529. Filed Sept. 8, 1894.
The arrangement consists in the arrangement of the solenoids and their cores and the special devices connected therewith transmitting motion to the lamp-electrodes. Operates on the "differential" principle.

Electric Arc Lamp, J. H. J. Haines, New York, & A. B. Fernald, Jersey City, N. J., 544,578. Filed Nov. 20, 1894.
Similar to patent below.

Electric Arc Lamp, J. H. J. Haines, New York, & A. B. Fernald, Jersey City, N. J., 544,579. Filed Nov. 20, 1894.
A carbon carrier in the form of a screw and a nut rotated thereby, a moving support for said nut, by which it and the rod may be lifted, and means mounted upon said support for acting upon and controlling the rotation of the nut.

Measurement:—

Electromagnetic Damper for Measuring Instruments, E. P. Warner, Chicago, Ill., 544,332. Filed Sept. 13, 1894.

Miscellaneous:—

Tracker for Mechanical Musical Instruments, H. C. Reichardt, Pottsville, Pa., 544,332. Filed Dec. 18, 1894.

Synchronism Indicator, R. D. Mershon, Pittsburg, Pa., 544,365. Filed Nov. 12, 1894.
For description see page 175, this issue.

Electric Rheostat, F. B. Badt, Chicago, Ill., 544,278. Filed May 31, 1895.
The resistance coils are embedded in a plate of glass, the glass being molded about the conductor in the formation of the glass. The glass plate is clamped between a pair of ribbed cast iron plates.

Electric Wire Containing Hat or Cap Band, A. M. Rodrigues, Brooklyn, N. Y., and E. D. Rockwell, Bristol, C nn., 544,419. Filed June 10, 1895.

Electric Gas Lighter, E. Orling, Stockholm, Sweden, 544,514. Filed Feb. 5, 1895.
Adapted especially for Welsbach burners.

Electrotherapeutic Appliance, J. E. Wiles, Milwaukee, Wis., 544,552. Filed Jan. 14, 1895.
A multiple cell battery of tubular form.

Electric Lighting Attachment for Gas-Burners, F. A. Webb, Beverly, Mass, 544,634. Filed Mch. 11, 1895.
Means for electrically lighting Welsbach or Bunsen gas burners.

Railways and Appliances:

Conduit for Electric Conductors for Railways, F. L. Capps, Newark, N. J., 544,283. Filed Sept. 18, 1894.
Details of construction to secure high insulation.

System of Electrical Distribution, S. C. C. Currie, New York, 544,289. Filed Nov. 27, 1893.
For description see page 179, this issue.

Conductor for Electric Railways, P. C. Just, Chicago, Ill., 544,306. Filed Feb. 6, 1893.
A conductor so supported as to allow expansion and contraction under changes of temperature.

Trolley for Underground Electric Railways, M. D. Law, Washington, D. C., 544,312. Filed Jan. 31, 1894.

Traveling Contact Device for Electric Railways, J. C. Love, Philadelphia, Pa., 544,313. Filed Sept. 5, 1893.

Electric Railway Conduit System, L. H. Sherwood, Mt. Vernon, N. Y., 544,391. Filed Sept. 7, 1894.
The conductor is placed within a continuous tube, and thus protected from water entering from above.

Switches, Cut-Outs, etc.:—

Multiple Fuse Switch, J. Melzer, Saaz, Austria-Hungary, 544,318. Filed Oct. 20, 1893.

Strong Current Arrester, F. R. McBerty, Downer's Grove, Ill., 544,368. Filed May 31, 1894.
A spring is released by the melting of a fusible conductor.

Automatic Safety Appliance for Electric Conductors, A. E. Hutchins, Detroit, Mich., 544,496. Filed May 9, 1893.
Automatically shunts the main current to the ground as soon as the main line breaks or sags.

Telegraphs:—

Printing Telegraph, C. L. Buckingham, New York, 544,345. Filed April 16, 1894.
Relates to type-printing machines, and is designed more particularly to adapt said machines for printing typographical characters in page form at high speed upon sheets of paper.

Printing Telegraph, C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 544,346. Filed Jan. 10, 1895.
Details relating to the above.

Printing Telegraph, C. L. Buckingham, New York, and E. Germann, Brooklyn, N. Y., 544,347. Filed Jan. 10, 1895.
Details relating to the above.

Printing Telegraph, C. L. Buckingham, New York, and E Germann, Brooklyn, N. Y., 544,348. Filed May 20, 1895.
Details relating to the above.

Fountain Ink Roller for Telegraph Registers, C. A. Rolfe, Chicago, Ill., 544,644. Filed Oct. 13, 1894.
A "fountain" ink wheel for telegraph registers.

Telephones:—

Telephone Switch, F. R. Whitney, Lewiston, Me., 544,335. Filed June 30, 1894.
Details relating to a suspension hook.

Multiple Switchboard System, O. A. Bell, Brooklyn, N. Y, 544,341. Filed Feb. 21, 1893.
Details of construction by which the provision of a special clearing out annunciator is avoided and by which an operator at one section of the switchboard is enabled to determine whether any line is busy.

Plug and Cord for Telephone Switchboards, F. R. McBerty, Downer's Grove, Ill., 544,369. Filed Sept. 18, 1894.
Its object is to produce an improved form of a device for securely attaching the flexible conductor to the connecting plug.

Automatic Signaling Device for Telephone Switchboards, F. R. McBerty, Downer's Grove, Ill., 544,370. Filed Dec 26, 1894.

Electric Grounding Switch, C. E. Scribner, Chicago, Ill., 544,383. Filed Dec. 6, 1887.
Intended for telephone switchboards.

Single Cord Grounded-Circuit System for Multiple Switchboards, C. E. Scribner, Chicago, Ill., 544,384. Filed Dec. 1, 1890.

Test Signal for Multiple Switchboards, C. E. Scribner, Chicago, Ill., 544,385. Filed July 7, 1891.
Its object is to provide a simple and effective means for producing a signal in response to a current of proper character in the test circuit.

Telephone Switchboard Apparatus, C. E. Scribner, Chicago, Ill., 544,386. Filed Dec. 26, 1894.
The object is to facilitate the work of the operator in establishing connection between lines by automatically controlling the connection and disconnection of her telephone with the plug-circuit employed in uniting lines.

Telephone Exchange System, C. E. Scribner, Chicago, Ill., 544,388. Filed May 13, 1892.
A modification of the "law" system. The object is to simplify the apparatus employed in connecting between telephone lines at the exchange.

Signal Apparatus for Telephone Exchanges, J. J. O'Connell, Chicago, Ill., 544,545. Filed Apl. 17, 1893.
Provides a visual signal for the "busy" test, and a similar signal whereby the operator at the calling office is informed when the connection is made at the distant office.

Apparatus for Telephone Exchanges, J. J. O'Connell, Chicago, Ill., 544,546. Filed Apl. 17, 1893.
Relates to a visual "busy" signal.

Electrical Signaling Apparatus, W. W. Dean, St. Louis, Mo., 544,567. Filed Sept. 24, 1894.
A plurality of electromagnets operating a signaling device, with an interlocking means whereby the magnets may separately or conjointly control the signals. Applicable to the "common battery" telephone system.

ELECTRIC HEADLIGHTS FOR THE SOUTHERN PACIFIC RAILROAD.

Electric lights will soon succeed oil lamps as headlights on all of the passenger train locomotives of the Southern Pacific Company. The company has been experimenting with electric headlights for some time, and at last has perfected a light that can be operated by a dynamo on the engine, which will illuminate the track for a distance of 2,000 feet. Oil lamps light the track for only 200 feet ahead of the locomotive, and when running at a high speed engineers are frequently unable to stop, after observing an obstruction on the track, in time to prevent an accident. The Southern Pacific will be the first railroad company in the United States to equip all of its passenger train locomotives with electric headlights.

THE CANADIAN ELECTRIC FORGING AND SMELTING CO., LTD., has been organized in Canada with a capital stock of $500,000. The company has acquired the patent rights for the Burton liquid electric forging and smelting process for Canada. The offices are located at 42 York St., Toronto, Can.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE PARTZ ACID GRAVITY BATTERY.

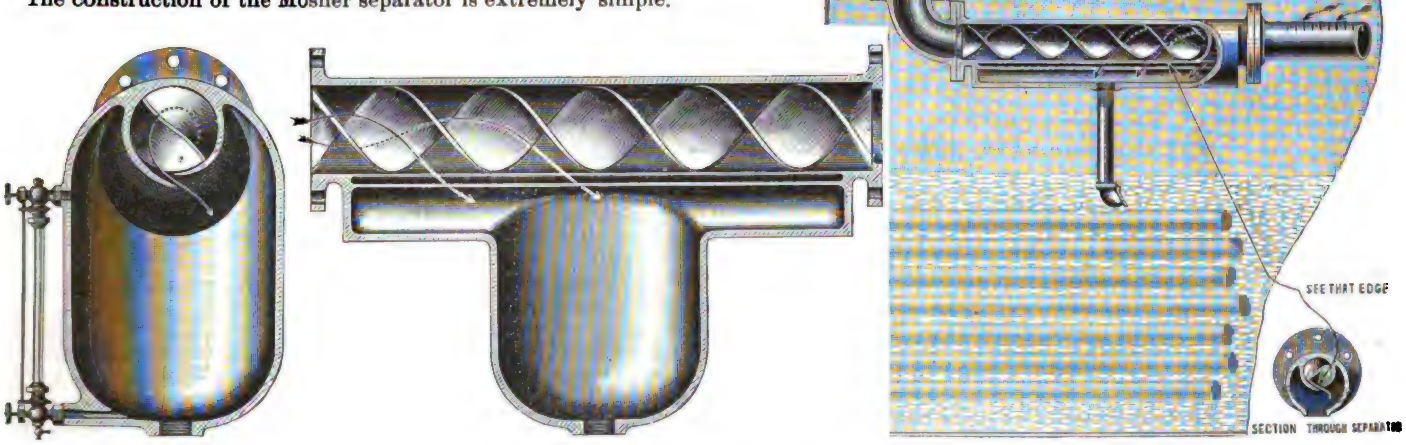
The S. S. White Dental Manufacturing Company has published a pamphlet in which the merits of the Partz "acid gravity" battery are set forth. The many applications of the battery are covered under the various heads: General purposes; physical laboratory and experimenting; coupled in various ways; for heavy bell work; as a substitute for sal-ammoniac cells; for physicians' office uses; on closed circuit; what feeding will do; for motor, etc., etc.

The results are also given of tests of the Partz batteries at the World's Columbian Exposition. The points of greatest importance practically demonstrated by these tests is the fact that when the electromotive force of the cells is apparently exhausted, the feeding in of a little sulpho-chromic salt restores them to full activity.

THE MOSHER STEAM SEPARATOR.

We illustrate in the accompanying engravings, the Mosher patent steam separator for separating all moisture from steam. The practical man will understand at a glance the principle of operation, which is the utilization of centrifugal force, acknowledged to be the only successful method of separation. The other important feature, and one which is found only in this separator, is that of at once isolating all water of separation from the current of steam, thereby rendering it impossible for any water to be again picked up and carried over to the engine.

The construction of the Mosher separator is extremely simple.



FIGS. 1, 2 AND 3.—THE MOSHER STEAM SEPARATOR.

As will be seen in Figs. 1 and 2, the steam conduit consists of a slightly enlarged section of the main steam pipe in which is located a worm or twisted plate. The wall of this conduit is of spiral form with one lip below the other, as is shown by the cross section Fig. 1, thus forming a slot through which all moisture is thrown to the collecting chamber below. Thus the steam is acted on many times in its passage around the twisted plate and the heavier particles being thrown outwardly by centrifugal force are shaved off and deposited in the isolated chamber below. From which it may be returned to the boiler.

The Mosher separator is also made with small collecting chamber, rendering it more compact and adapted to places where other styles would be excluded on account of limited space. The compact style is peculiary adapted to many other uses, among which is the extraction of oil from exhaust steam, rendering a considerable saving in oil and in destruction of roofs; on exhaust pipes when steam is used for heating purposes, to keep pipes and radiators from becoming clogged with oil and rendering them inefficient; between cylinders of compound engines to extract water of condensation; between low pressure cylinder and condenser to avoid the clogging up of condenser by oil from cylinders; also in ice and refrigeration plants to extract the oil from ammonia gas, thus providing against pipes becoming coated on the inside by oil in cylinder lubrication, which renders them very inefficient. In the last named capacity the Mosher separator is the only device that has successfully accomplished this extremely difficult problem of separation.

Many boilers are subject to violent priming or foaming during which a considerable amount of water is carried out of the boiler. In such cases the trouble may be entirely avoided by the introduction of a Mosher separator inside the boiler, as shown in Fig. 3. The separator, which by reason of its small size may be introduced through the ordinary manhole and connected between throttle and a perforated dry pipe will prevent any possibility of wet steam leaving the boiler due to primage and therefore furnish dry steam at all times regardless of how severe the boiler may "foam" or "prime."

The Mosher separator is built in sizes from one and one half inches to any size required. The larger sizes are constructed of steel castings or boiler plate when so desired and will withstand any desired pressure. Separators are tested for two hundred pounds working pressure per square inch. These separators are built by Charles D. Mosher, No. 1 Broadway, New York, who will be pleased to send his "Treatise on The Steam Separator" to all who desire it.

THE GRAND AVENUE ELECTRIC WORKS, KANSAS CITY, MO.

An item in a recent issue may have given the impression that the Grand Avenue Electrical Works, of Kansas City, Mo., were a branch of the Standard Telephone Company, of Wisconsin. We are requested to state that such is not the case, but that the Standard Company is promoting a telephone exchange with the aid of the Grand Avenue Company, and is meeting with considerable encouragement among telephone users.

AN "IDEAL" ENGINE ROOM.

We have received from the Harrisburg Foundry and Machine Works, Harrisburg, Pa., a pamphlet containing press notices of the up to-date engine room at Keith's New Theatre, Boston, on which no care or expense seems to have been spared. This room is supplied with 3 Harrisburg Foundry and Machine Company's Ideal Engines, 15½ x 14" cylinder, which give an aggregate of 525 horse-power. They are used to run 6,000 16 candle-power lights, at 110 volts. The engines run at 270 revolutions, and are practically noiseless. The finish of the machinery is excellent, the trimmings all being of the best nickel plate.

6,000 H. P. OF HARRISBURG IDE AND IDEAL ENGINES.

W. R. Fleming & Co., representing the Harrisburg Foundry and Machine Works, Harrisburg, Pa., report the following list of Ide and Ideal engines as recent sales made through their offices in New York, Boston, and Philadelphia, exclusive of sales outside of these territories.

1-160 H. P. direct connected to Siemens-Halske dynamo for Hotel "San Remo," N. Y.; 1-50 H. P., direct connected to General Electric dynamo, for N. Y. Life Ins. Co., N. Y.; 3 150 H. P., direct connected to Crocker-Wheeler dynamos for Hotel "Walton," Philadelphia; 2-50 H. P., direct connected to General Electric dynamos for Fahys Building, N. Y.; 3-50 H. P., direct connected to Eickemeyer dynamos for elevator service, Fahys Building, N. Y.; 1-150 H. P., tandem compound engine to S. O. & Co., Ansonia, Ct.; 1-80 H. P. and 1-120 H. P., direct connected to General Electric dynamos for Germania Life Ins. Building, N. Y.; 2-80 H. P., direct connected to General Electric dynamos for Hotel "Stenton," Philadelphia; 1-40 H. P. and 1-60 H. P. for W. H. Hayden, Bath, Me.; 1-25 H. P. to Brigham Electric Co., Boston; 2-400 H. P., direct connected to General Electric railway generators for export to Rio Janeiro; 1-30 H. P. for Columbia Spinning Co., New Bedford, Mass.; 1-20 H. P. for new City Hall, Brockton, Mass.; 1-300 H. P. tandem compound Ide for export So. Africa; 1-75 H. P. Ide for American Surety Bldg., N. Y.; 2-750 H. P. tandem compound railway engines, Ide, direct connected to General Electric dynamos for Philadelphia, Castle Rock & Westchester R. R. Co., Philadelphia;

2-80 H. P., direct connected General Electric dynamos to Bar Association Bldg., N. Y.; 2-50 H. P., direct connected to dynamos, Lorsch Bldg., N. Y.; 3-125 H. P. Harrisburg tubular boilers, and complete steam construction for Custom House, N. Y.; 2-200 H. P. tandem compound engines and 1-40 H. P. simple engine for magnificent new Hotel Royal, Poinciana, Fla.; 1-100 H. P. to Larchmont Elec. Co., Mamaroneck, N. Y.; 1-60 H. P. for "Mail & Express" Building, N. Y.; 1-25 H. P. engine and 1-25 H. P. Harrisburg boiler for General Electric Co., Foreign Dept., Schenectady, N. Y.; 1-15 H. P. Manhattan Ry. Co., N. Y. City; 3-125 H. P., direct connected to Siemens-Halske dynamos for apartment house, 75th St. and Columbus Ave., N. Y.

RECENT CHLORIDE ACCUMULATOR INSTALLATIONS.

A BATTERY of Chloride accumulators manufactured by the Electric Storage Battery Co. of Philadelphia, having a capacity of 216 K. W. hours, has been sold to the Argentine Republic for furnishing light and power in one of the Government Buildings in Buenos Ayres. A contract has also been closed with the German Liederkranz Society of New York City for a lighting battery with a capacity of 182 K. W. hours. The Western Union Telegraph Co. is installing at Washington, D. C. under the supervision of its Asst. Electrical Engineer, Mr. G. W. Gardanier, 796 Chloride accumulator elements of various sizes.

THE HOGAN BOILER COMPANY'S "PROOFS."

"PROOFS" a pamphlet published by the Hogan Boiler Company, Middletown, N. Y., shows in detail the advantages of the Hogan stationary and marine water tube boilers, which it makes in twenty-four sizes, in units of 75 H. P. to 800 H. P. Tables are given showing extra first cost of materials and appliances, and average extra floor space necessary and extra first costs, in steam plants varying from 1,000 to 10,000 horse power ordinarily necessary. Under all these heads a twenty per cent. greater efficiency is shown for the Hogan boiler, with a great economy in fuel.

THE MASSACHUSETTS FAN CO.

The business of The Davidson Ventilating Fan Company has been acquired by the Massachusetts Fan Company, with offices at 41 Federal St., Boston, Mass. The Davidson fan will be manufactured and sold by the new company. A large stock of fans is now being made up, and orders of any size can be filled without delay.

BRANCH OFFICES OF THE ELECTRIC STORAGE BATTERY CO.

IN order to meet the growing demand for its products, the Electric Storage Battery Company has opened branch offices at 383 Exchange Building, Boston; 309 Dearborn St., Chicago; 15 First St., San Francisco; 215 North Calvert St., Baltimore; and 66 Broadway, New York. The office of the Electric Launch Company will be at Morris Heights, New York City.

THE ELECTRICAL MAINTENANCE COMPANY.

THE ELECTRICAL MAINTENANCE CO., 50 Broadway, New York, is doing an active business in inspecting and keeping in repair electric machinery of all kinds—dynamos, motors, electric elevators, switchboards, storage batteries, etc., etc. It holds itself liable to replace burned-out armatures, field coils, commutators and brushes, and other portions of the electrical machinery damaged otherwise than by ordinary wear and tear, at a yearly contract price, which is a fixed charge to customers, entirely releasing them from the responsibility of the successful working of their electrical plants.

This company has now made permanent arrangements with Messrs. A. K. Warren & Co., the largest and best equipped electrical repair shop (official repair shop of the General Electric Company) in the country, to do its heavy repairing. All inspections are made from this office by its experts regularly, and a report of the inspection is mailed monthly.

A BARGAIN IN BIG ENGINES.

OWING to the recent consolidation of the Edison and the Citizens' Companies in Brooklyn and a redistribution of the station loads, the two magnificent engines installed recently in the Citizens' Electric Light Co.'s station, are to be dispensed with and are now offered at a bargain by Paul T. Kenny, 126 Liberty St., New York. The following is a description of the engines:

McIntosh & Seymour vertical four cylinder, triple expansion, automatic engines; size of cylinders, 18 x 24, 21 x 24, 23 x 24; R. P. M., 155: steam pressure, 150; and horse power of each 400. The cylinders are provided with the regular McIntosh & Seymour double valve arrangement. The main driving wheel between cylinders is 11', 6" in diameter and 48" face, weight 16,000 lbs. The engines have shaft governor and overhanging cranks, and are fitted with oil tanks, sight feed outlets and oiling devices complete. A cut of the engines is shown on page xviii of the advertisements in this issue.

CONTRACTS AWARDED FOR THE NEW WILKES BARRE, PA. ELECTRIC LIGHT STATION.

THE WILKES BARRE ELECTRIC LIGHT CO., for whom Mr. J. H. Vail is acting as supervising engineer, has awarded the following contracts: Boilers, 900 H. P., to the Stirling Boiler Co.; engines, 400 H. P. Armington & Sims engines, to E. P. Hampson & Co., general agents; stack, steel plate, brick lined, self-supporting stack, to Riter & Conley, Pittsburgh, Pa.; pumps, vertical, deep well pumps, to H. R. Worthington & Co.; iron roof structure and other iron work, to N. J. Steel & Iron Co., Trenton, N. J.; shafting and friction clutch pulleys, to Falls Rivet & Machine Co., Cuyahoga Falls, O.; traveling crane, to Maris Bros., Philadelphia, Pa.; heaters, to Warren Webster & Co., Philadelphia, Pa.

THE PEERLESS RUBBER MANUFACTURING COMPANY.

We have received a catalogue and price lists of the Peerless Rubber Manufacturing Co., 16 Warren street, New York, in which the many branches of their wide range of rubber and other goods are treated in detail. The catalogue extends to 72 pages, and forms a useful guide to those on the lookout for reliable forms of packing, gasket, steam hose, rubber and leather belting, matting, pads and miscellaneous rubber goods.

BIDS WANTED.

MR. LOUIS R. SCHULTZ has been retained as consulting engineer for R. J. Thompson & Co., cor. 11th and Chestnut Sts., Philadelphia. He is receiving proposals up to Aug. 23 for a 200 H. P. lighting and power plant. Direct connected dynamos will be used.

WESTERN NOTES.

THE DALTON & LARK MINING CO., of Bingham, Utah, have recently put in a 100-light Dayton dynamo, to light their shafts, mines and building. The plant was installed by R. W. Nicol of Salt Lake City.

THE METROPOLITAN ELECTRIC COMPANY, Chicago, has secured the Western Agency for the "Ship" cored carbons. These carbons are imported from Vienna, Austria. They have already established an enviable record, and as the Metropolitan Company has placed a large stock order, they will be able to fill all orders for imported carbons promptly.

THE FRANKLIN ELECTRIC CO., of Miamisburg, O., announce that they have bought the entire business and good will of the Franklin Electric Co. formerly of Cincinnati, O. and will continue the manufacture of battery motors of all sizes, electric alarm clocks, etc. They will also handle a full line of students' and experimenters' supplies, such as castings and parts of dynamos, motors, steam and gas engines, either partly finished or in the rough. They will strive to furnish anything the young electrician, student, or experimenter may want, and at lowest prices.

LAMPASAS, TEXAS.—The Lampasas Electric Light Co. has been organized with a capital stock of $20,000. Its officers are: J. T. Donovan, president; J. C. Matthews, vice-president; W. H. Browning, secretary and treasurer; and E. A. Maxwell, manager. It has 14 miles of Okonite wire circuit, and operates from one Heisler 800 light machine, and one Jenney of 800. Water power is used, the wheel being a 93 H. P. Leffel. The company is in the market for arc lamps for their Heisler system, 2,000 C. P., 5 amp., series, ½ inch carbon. The power house is of stone. There is a fine opening in the neighborhood for power transmission. From the Colorado River, 15 miles distant, 1,600 H. P. could be taken. This, transmitted to Lampasas, could run all the street cars, gins, and cotton mills in the city.

NEW YORK NOTES.

THE Perkins Electric Switch Mfg. Co., of Hartford, Conn., through their New York representative, Mr. C. I. Hills, have sold 50 Waterhouse-Gamble ornamental arc lamps, to be installed in the new dry goods store of M. C. Spencer & Co., on 125th St., New York.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XX. AUGUST 28, 1895. No. 382.

THE GROWTH OF LONG DISTANCE COMMERCIAL TELEPHONY.

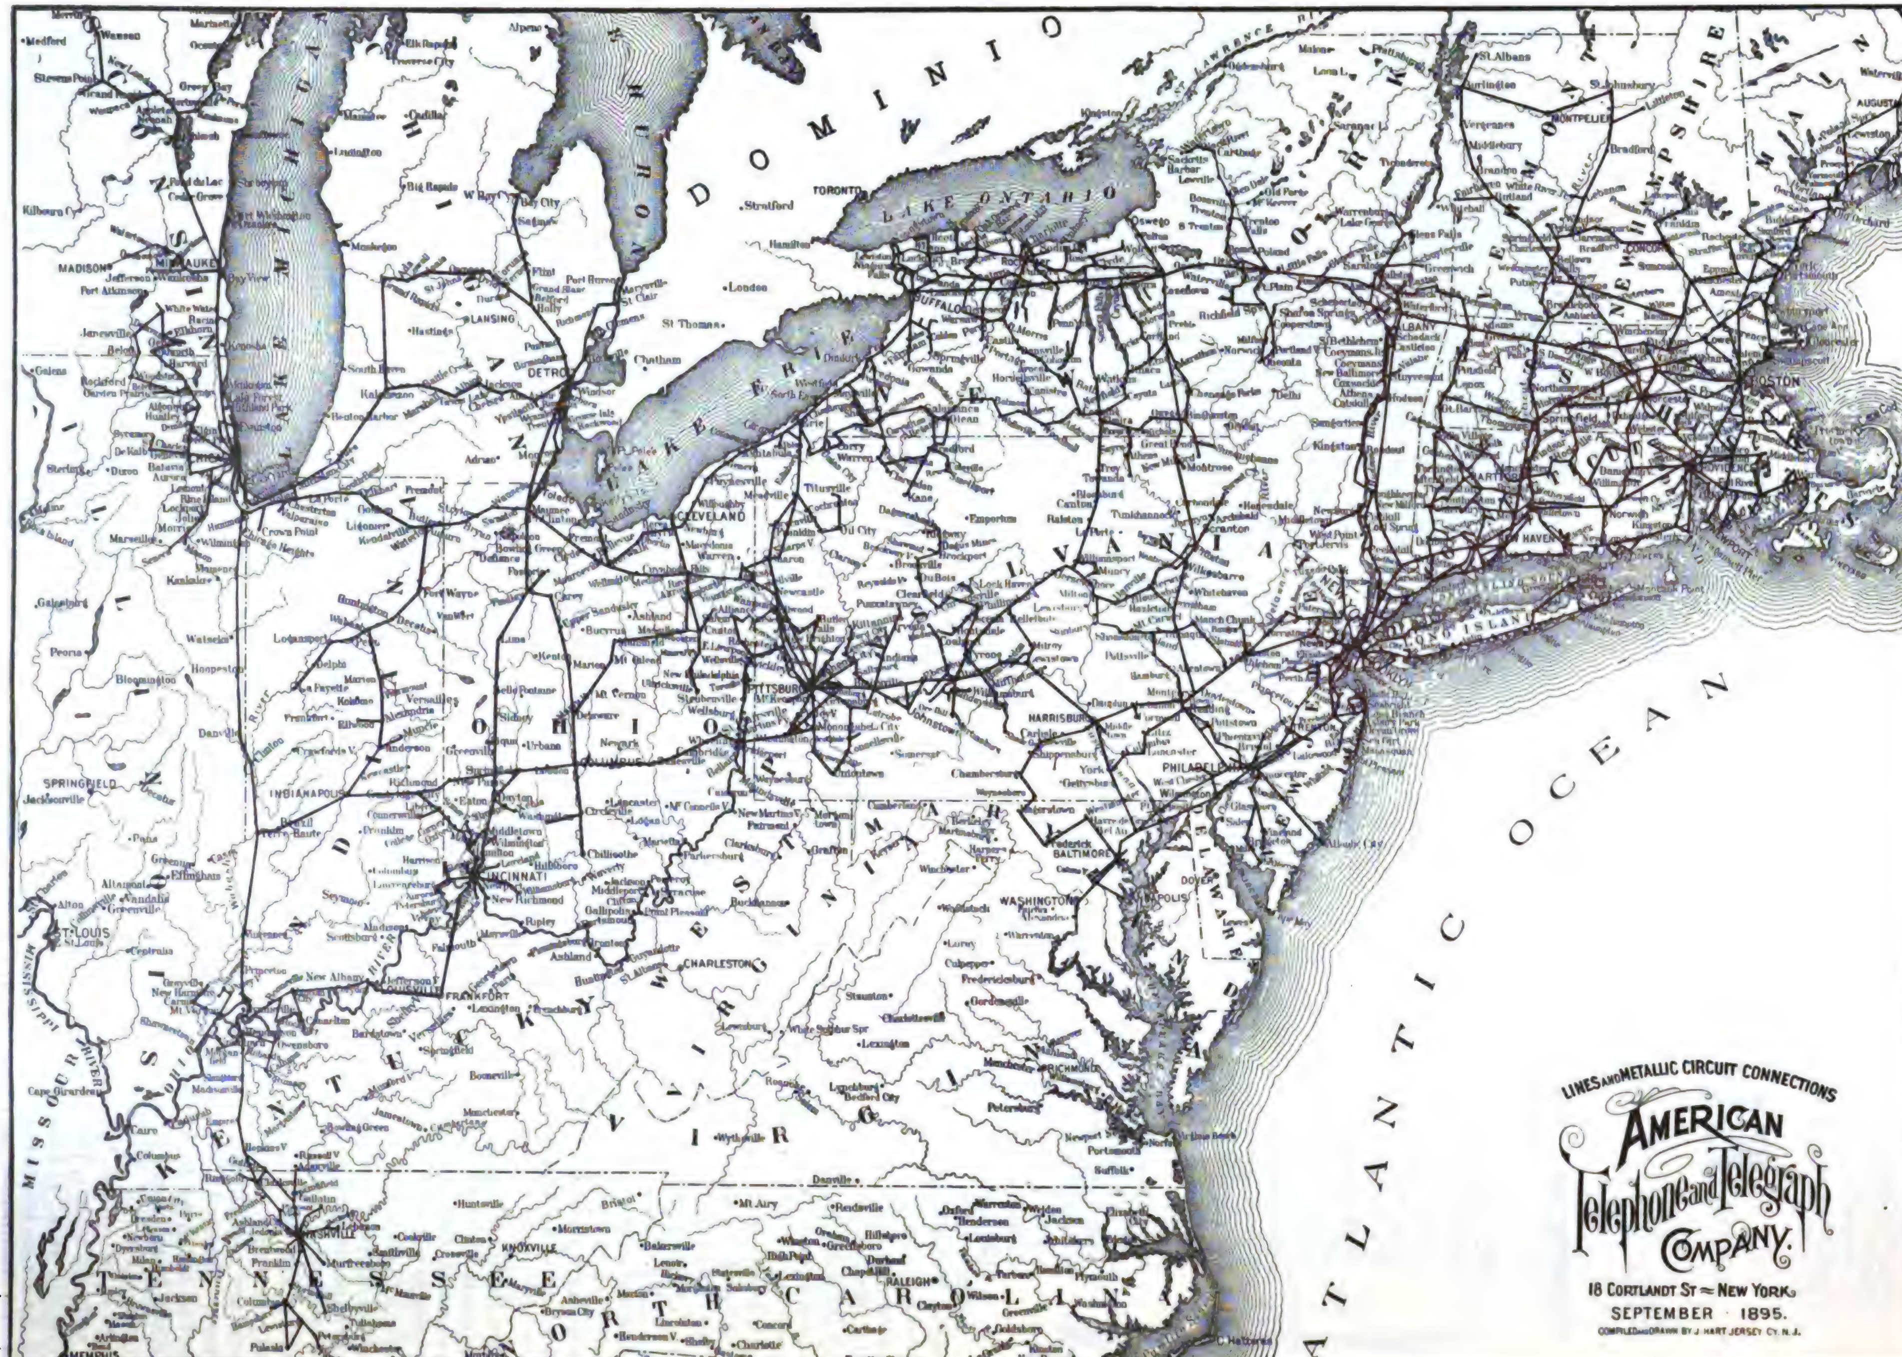
THE last report of President Hudson of the American Bell Telephone Company stated that the total investment in telephone property in this country at the close of 1894 was $77,500,000. It would appear that no less than 10 per cent. of this large sum is represented distinctively in what is known as the "long distance" service as organized and developed by the American Telephone and Telegraph Company. This corporation, known in popular parlance as the Long Distance Company, had invested up to the end of 1894 in line construction, equipment and supplies the amount of $7,460,662, upon which the 1894 gross earnings were $1,011,961, an increase over 1893 of nearly 13½ per cent. Such figures would in themselves indicate the rapid development within the last five years of the long distance telephone system, for it is within that period that the greatest strides have been made. The first line was constructed by the American Telephone and Telegraph Co., which was, as everybody knows, specially organized by Bell interests for this particular work. It dates back to 1885, and then extended merely between New York and Philadelphia. The system to-day includes 55,000 miles of pole line and 265,000 miles of wire, all of the very latest and best type of construction. Between such cities as New York and Boston and Philadelphia, there are as many as 40 wires in the line. The physical and numerous other details of the system were fully set forth in THE ELECTRICAL ENGINEER of May 4 and 11, 1892, by Mr. Herbert Laws Webb, and of Dec. 14, 1892, by Mr. Joseph Wetzler. It will therefore suffice to mention here that the standard size of wire employed has been No. 12 B. S. G.—.104 inch diameter—of hard drawn copper, having a resistance of 5.2 ohms to the mile; the poles being 40 footers with 130 feet length of intermediate span.

From the development of this system in 1885, down to the present time, the work of extension has been carried on, unhasting but unresting, so that it now has grown into the gigantic network shown in the map to be issued by the American Telephone & Telegraph Co. next month, and presented on page 198 of this issue. This map of which we are thus enabled to present an advance proof has many features of significance. East of the Hudson River, and including the whole New England region the system is already strongly interlaced, and, when the local exchange systems are considered, leaves very few vacant patches of territory. Around Philadelphia again the lines are dense, but not so much so as in Buffalo and Pittsburgh; while Cleveland is apparently limited still in its "long distance" resources. Part of Michigan is untouched, and although Chicago is, of course, the centre of a cobweb of wires as it is of railroad tracks, the service northward to Milwaukee and Merrill, Wis., is slimmer. Going south, Cincinnati is found to be an important nucleus, but between the Ohio River and Baltimore, on Chesapeake Bay, the country is still a blank, speaking from the "long distance" standpoint. Directly southward from Cincinnati the lines run to Louisville, and thence with strategic slants and twists to Nashville, Tenn., and far away again to Shelbyville, Fayetteville and Pulaski. It will be observed that from Chicago to Terre Haute, the line parallels the Indiana State border, leaving bare all the territory westward; but it is a fact that that region is being rapidly filled in and occupied and that the material is already deposited in St. Louis for the next big section of work.

All over the sections completed the talking is remarkably good. The present writer has frequently conversed with New York from points as remote as Chicago and Milwaukee, and has had perfect results, even in the wet months of October and November. It will be remembered moreover as one of the incidents of the memorable blizzard of 1889 that the only direct interchange of news between New York and points outside was had by means of the long distance wires; and that while telegrams between New York and Boston were necessarily sent via Ireland, over the Atlantic cable, people in their New York and Boston offices were quietly chatting over the telephone as though nothing had happened.

The American Telephone and Telegraph Company now issues a list of over 2,000 places connected by metallic circuit—*i. e.* two wires for each station—with the Long Distance system, but even this does not give an idea of the work of this character now being done, for the reason that it does not include the local exchange groups of cities still to be brought within the service and already enjoying intercommunication over lines 300 and 400 miles long. Cities like Minneapolis, St. Louis, New Orleans, Kansas City, Omaha, Denver, Salt Lake City, Portland, Los Angeles, Fort Worth, Galveston, Mobile, Atlanta, are all the foci of separate systems, well developed, and only awaiting the course of events to be assimilated with and joined into the regular Long Distance network. In the Southern States these local exchanges and their extra-territorial lines are so well recognized as ready for blending that for months past a rumor has been in persistent circulation to the effect that should competition at various points become severe, the interconnected lines between cities would be thrown open free to the subscribers who stood by the local Bell exchanges.

This brings us, first, to the question of rates. The schedule of rates for five minutes' talk from New York subscribers' own stations and from the 1200 pay stations scattered all over the city appears at first sight to be extremely high, and must undoubtedly be radically reduced as time goes by; but when it is considered that an ordinary man can easily talk 150 words in a minute, $9 for 750 words to Chicago, with interlocutory responses, in the day time, is not so much out of the way, as compared with telegraphy; while the night rate of $4.50 for the same quantity is more reasonable still. Besides this, there is now in vogue a system of sending out from the nearest pay station for the person wanted, if not a subscriber, and, without extra charge, bringing him in for the desired communication. A scale of commutation rates also exists, averaging 15 and 20 per cent. on a certain bulk of business. Be the rate high or low, it has for some time past



Official Map to be Issued September 1, of the Long Distance Telephone System in the United States—Circuits Shown in Heavy Black Line.

been asserted that the growing use of the Long Distance lines has seriously affected through railway travel and interfered with hotel patronage in the large cities.

It is interesting in this connection to recall the fact that prior to the extensive telegraph consolidations in 1866, the telegraph rate from New York to Chicago for only 10 words was $2.05 with 15 cents for each additional word; while to Portland, Ore., it was $10.20 and 77 cents per extra word. The rate to Chicago to-day seems infinitely smaller, and yet it is dearer than that charged for the long distance telephone, unless a special rate were obtained for so long a message as 750 words. The elements of direct intercourse and of immediate access may be left wholly out of account, and the advantage would still seem to rest with the telephone even at its undeniably high tariff.

The expansion of this long distance telephone service has therefore already marked a distinct limitation for the telegraph between cities, and in some quarters the complete supercession of the telegraph is looked for, although Mr. P. B. Delany has suggested, with wonted fertility, that the telegraph lines be hereafter devoted to the instantaneous transmission of the mails. The relations between the American Bell Telephone Company and the Western Union Company have since 1879 been determined by a contract which in this issue of The Electrical Engineer is for the first time made public, and which should apparently expire next year. As this contract shows, the telephone has during this period paid to the telegraph a commission of 20 per cent. on its gross rental income for the privilege of doing business free from vexing competition; but the question has of late assumed shape as to whether the telegraph has not in a sense been selling its birthright for a mess of pottage. Some of the daily newspapers have assumed that the state of affairs betokens irrepressible and inevitable conflict, with an utter disuse of the telegraph in the long run. As a matter of fact, no electrical appliance has ever yet completely given way before another; it has merely found its more legitimate sphere of strictly profitable use; while dealers in electrical supplies report that the recent great increase in the number of private telephone lines has been accompanied by a very brisk demand for telegraph instruments to be switched in and out of circuit. Combination of telegraphy and telephony over the same wire may yet be seen to be commercially feasible, and it is to be borne in mind that the new copper circuits of the Western Union and Postal Telegraph Companies could well do some independent telephonic work if it were advisable. Be this as it may, there are many indications that the habit of telegraphing does not gain ground, while the practice of telephonic intercourse grows at an extravagant rate. The average of about one telegraph message per year per head of population appears to be steady in this country, but in the cities it now falls below that, showing the limiting effect of the telephone, assisted by the district messengers. Even in England, the ratio is only two messages per head. Hence, also, there would appear to be little inducement for the telephone companies to try duplex telegraphy on their circuits. Of late years extremely little has been heard in this country of the combined telegraphic and telephonic systems with which the names of Van Rysselberghe and Rosebrugh have more particularly been connected. The reason may be that in telephony as in telegraphy, the apparatus steadily and all the time tends away from complexity and back to pristine simplicity. Telegraphers all swear by Morse, and everbody makes and uses the early Bell receiver.

The amount paid by the American Bell Telephone Company to the Western Union Telegraph Company has now reached substantial figures. The earlier statistics are not easily obtainable, but the item of "Commission" in 1883-4 ran as high as $354,856, while in ten months of 1884, when the American Bell financial year was changed, it reached $325,207. The subsequent years run as follows:

COMMISSION.

Year.	Amount.
1885	$396,650
1886	404,111
1887	433,578
1888	467,471
1889	511,215
1890	575,221
1891	614,019
1892	648,689
1893	690,380
1894	459,958
	$5,201,292

If to this sum we add $300,000 per year for the five years preceding 1885, and $500,000 for 1895, we reach a truly grand total of $7,250,000, which, according to this "Commission Account," has gone into the pocket of the Western Union Telegraph Company in about fifteen years, as the consideration for which it agreed to sit still and do nothing in telephony.

PHOSPHORESCENCE.

In a Note in a recent number of the *Comptes Rendus*, M. Gaston Séguy gives the result of some experiments made by him with regard to phosphorescence in electric discharge tubes. As is well known, the phenomenon of phosphorescence is observed in tubes containing rarefied oxygen through which an electric discharge has been passed. In the course of numerous experiments on nitrogen and its components, M. Séguy finds that nitrogen also phosphoresces, at least in the presence of a metallic bichloride. The tube used by M. Séguy consisted of three bulbs, fused together and furnished with electrodes. These were filled with nitrogen obtained from atmospheric air by the Brin process, a vacuum being then made, and the vapor of bichloride of tin being added. If an electric discharge is passed, the tube glows brilliantly, and the glow persists after the interruption of the current. The glow is a reddish color during the discharge, whilst that of an oxygen tube is a grayish violet. The phosphorescence is a milky white, filling the whole tube with the exception of a few centimetres near the poles. This glow attains a maximum brilliancy immediately after the interruption of the current, and gradually disappears at the end of 10 sec. or more.

METHOD OF MEASURING ELECTRIC CAPACITIES.

Mr. H. Bordier, in a paper read before the Académie des Sciences, decribes a method of measuring electrical capacities, based upon an experiment by Prof. D'Arsonval. If condensers of increasing capacity are placed successively in series on the same induction coil, and if, either by the aid of a rheostat or by moving the coil by predetermined steps, the moment is found determined in which the least sensation produced by the current on the skin is perceived, it is found that this moment varies for each added capacity. With a microfarad divided into tenths, it is stated to be easy to find two positions either of the rheostat or of the coil which correspond to the initial sensations produced by each tenth of microfarad added. The method allows a very approximate measurement of the capacity of the body of man to be obtained. The results showed:—First experiment, 0.002 microfarad; second experiment, 0.003 microfarad; average value, 0.0025 microfarad. This capacity is about 58 times greater than that of a homogeneous conductor, the surface of which would be equal to that of the human body. It is suggested that this capacity, relatively large, of the human body is due to phenomena of condensation occurring in the heart of the organism.

RESEARCHES ON THE ELECTRIC DISCHARGE OF THE TORPEDO.[1]

(Lighting Lamps and Geissler Tubes.)

BY A. D'ARSONVAL.

As I have maintained for several years past, the muscular contraction and the discharge of the electric organ seem to me to be assignable to the same cause, namely: the variations of surface tension, that is, the same principle which is embodied in the capillary electrometer of M. Lippmann. The discharge of the electric organ is but an exaggeration of the electric oscillation which is observed in the muscle when it contracts.

In order to register the phases of the discharge of the torpedo, I employed a special instrument called a galvanograph, consisting essentially of a very light coil of aluminum, over which is wound the circuit through which the discharge passes. This bobbin is fixed to the centre of a rubber diaphragm tightly stretched on a Marey air drum. The movable coil is placed in a strong magnetic field, the movements of the first drum being transmitted to a second one, which amplifies the motion, and carries a registering lever, which marks on the surface of a smoked cylinder. For the registering of the strength of the current a stretched silver wire was employed, the elongation of which, due to the heating effect of the current, was registered on a cylinder.

In order to take a measurement, the torpedo is placed on a cast metal plate, holding a layer of sea water of one centimeter depth so that the animal can breathe during the experiment. Out of sheet tin foil there are cut two electrodes having the form of the electric organs, and these two sheets are applied to the dorsal surface of these organs, and joined together by a band of tin-foil of 5 centimetres width, and fairly thick. The lower metallic plate on which the fish rests constitutes the negative electrode and the sheets of tin foil the positive electrode of this living electric generator. These are the electrodes which are connected to the different apparatus designed to measure or to render visible the discharge of the organs.

In order to provoke the discharge it suffices to pinch even lightly the edge of the fins of the fish with a pair of dissecting tweezers. Under these conditions the torpedo in general gives but a single discharge, but if the pinching is violent the discharges are multiple, and troublesome to register.

The curve inscribed by the galvanograph shows that the discharge is not continuous. It consists of 6 to 10 successive discharges, which increase from the beginning and follow one another at periods of $\frac{1}{100}$ of a second. The intensity attains its maximum in general after the third discharge, and then gradually diminishes to zero. The current always passes in the same direction, the back of the animal always being positive and the belly always negative. The curve resembles absolutely that of muscular contraction, the intensity increasing rapidly to a maximum and then falling to zero more slowly.

The mean duration of the discharge varies between $\frac{1}{10}$ and $\frac{5}{100}$ of a second, at a temperature of 19 degrees C. On torpedoes of 10 to 14 inches in diameter, kept for eight days in the basins of the laboratory, I obtained the following data: Electromotive force varies between 8 and 17 volts, and the current strength between 1 and 7 amperes. In possession of these data, I have thought that it was possible to bring before the eyes of the public the energy of the discharge under a more tangible form. For this purpose I employed the following arrangement, which succeeded very well. I took an incandescent lamp, requiring 4 volts and 1 ampere, and connected it to one of the electric organs. On pinching the animal, this lamp lights up and maintains a white heat for an instant. It is prudent to put the lamp in connection with only one of the organs, and to pinch the animal lightly, otherwise the lamp is invariably burned out, as happened to me the first time that I made the experiment. I have been able to put three to six lamps in series and bring them to a white heat. I have likewise succeeded when placing them in parallel. Not having a larger number of lamps at my disposal I was limited in my experiments which demonstrated in a sufficiently exact manner the correctness of the results obtained with the registering apparatus. With the Deprez-Carpentier amperemeter, having a range of 5 amperes, the needle was thrown far beyond the scale. By throwing the discharge into a small Ruhmkorff I have also succeeded in brightly illuminating two Geissler tubes. The two organs act synergetically, and with the same intensity, as can be readily demonstrated by placing an electric lamp on each organ. The two lamps light at the same instant, and reach the same brightness, although the circuits are separate.

The organ becomes exhausted quickly; after 4 or 5 discharges, repeated one right after the other, the lamp burns more and more feebly. If one has employed the current of but one organ, and then carries the lamp to the second organ, which has remained on open circuit, one obtains a current which will light up the lamp brightly. This fact proves that the voluntary nervous incitation does not suffice to exhaust the organ, and that it is in the organ itself and not in the nervous system that the electricity is produced. Five or ten minutes of rest brings up the discharge to its original strength, if light pinching has been employed.

By inserting two thermo-electric needles into the organs I have observed that during the discharge the organ heats up from $\frac{2}{10}$ to $\frac{3}{10}$ of a degree; but only when short circuited on itself. On open circuit I have not observed any heating, notwithstanding repeated pinchings.

By placing on the organ a stethoscope during the discharge I have been able to perceive a low sound corresponding to about 100 vibrations per second, showing that the organ is the seat of vibrations, such as those which take place in the muscles during voluntary contraction. I have also observed a retardation in the discharges between the anterior and the posterior part of the same organ, amounting to $\frac{4}{100}$ of a second. Is it possible that the organ consists of separate parts having independent discharges?

Finally, I have not observed any difference of potential between the two faces of the organ when in repose. This difference only shows itself at the moment that the animal throws out voluntarily its discharge.

I am pursuing these researches, and I shall make known shortly to the Academy the influence which the principal physical agents and various poisons exercise on the nerves and muscles. It will then be simple to show you the physical theory of animal electrogenesis which I have proposed and to explain all the phenomena previously known, and which led me to discover these new ones.

1. Abstract of a communication to the French Academy of Sciences.

THE HORSE POWER OF A LIGHTNING STROKE.

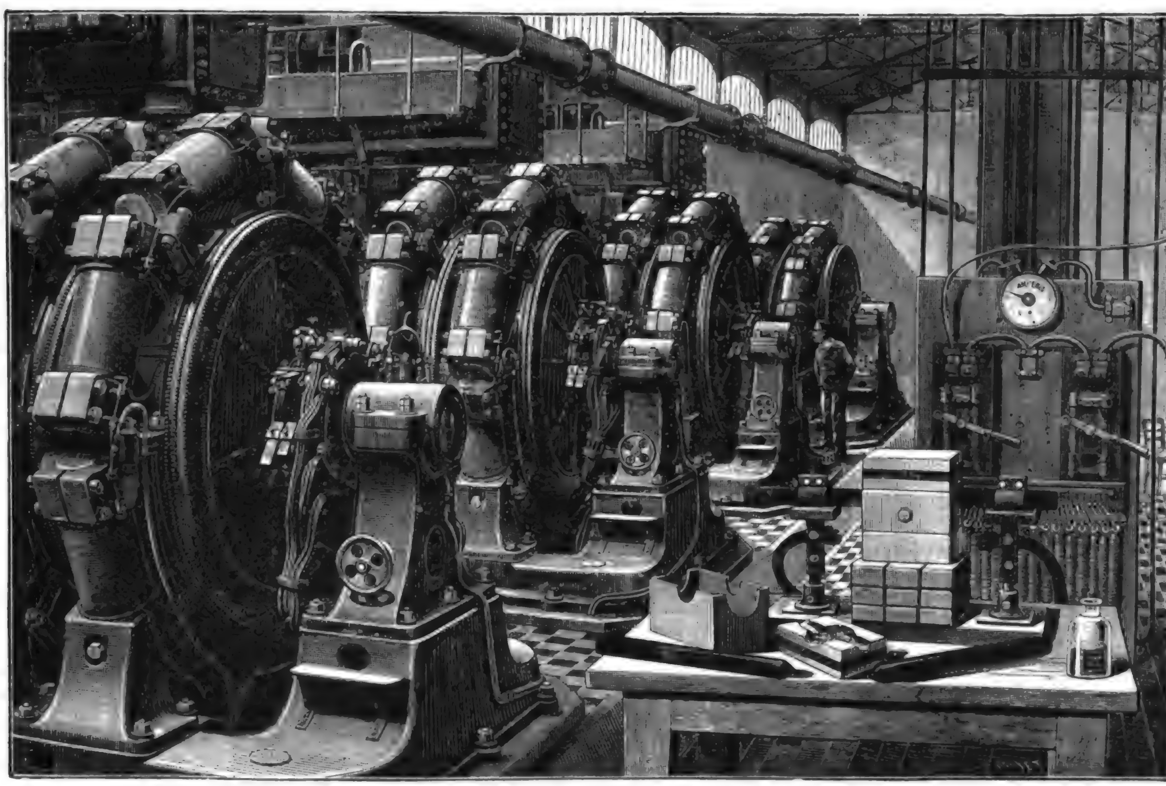
In a recent issue of the *Archiv für Post und Telegraphie* Prof. Hoppe gives some interesting details of the energy developed by a lightning stroke. At Klausthal a lightning stroke struck the wooden post of a house and fused two nails 4mm. thick. Experiments made afterwards by Messrs. Siemens and Halske, of Berlin, showed that a current of 200 amperes and 20,000 volts was required to do this work in one second. This represents about 7,000 H. P., and taking the duration of the lightning as one-tenth of a second the total power would be ten times as much.

THE ELECTRIC FURNACE AND CHEMISTRY AT HIGH TEMPERATURE.[1]

BY H. MOISSAN.

THE reverberatory electric furnace with movable electrodes which we built in 1892, and successfully improved since that time, is of great simplicity. By means of this apparatus we have been able, thanks to a sufficiently high temperature, to reproduce diamonds, to effect crystallization of the metallic oxides, the reduction of oxides heretofore deemed irreducible, the fusion of refractory metals, the distillation of lime, silicon, zirconium and of carbon, and finally the abundant vaporization of metals, such as platinum, copper, gold, iron, manganese, aluminum and uranium. The operation of our apparatus is of the most simple character. The current is carried by two flexible cables to the carbon electrodes. The contact is established, the arc starts and, by withdrawing the electrodes more or less, this powerful spark is given a constant length which depends on the power of the current, and on the conductivity of the metallic vapors which fill the furnace.

From the beginning of the experiment a penetrating odor of hydrocyanic acid is produced, brought about by the combination of the nitrogen in the furnace, with the acetylene which is formed at the beginning. This is an energetic reproduction of the beautiful synthesis of hydrocyanic acid obtained by M. Berthelot. A purple cyanogen flame first illuminates the arc; then this color disappears and the light becomes white. The lime which forms the interior of the furnace soon begins to melt and to run like wax, and then to boil, and in a few minutes the electrodes are brought to red heat, a torrent of vapor issuing from all sides with a constantly increasing intensity. The lime distills in abundance, and covers the supports of the electrodes with a white film. Thus, when utilizing the current of a machine of from 100 to 300 H. P. we have in the middle of the furnace an enormous temperature, produced by the electric arc; a few centimetres below, the crucible which encloses the matter experimented on; and below this, a wall of lime in full ebullition. The bad conductivity of this lime is a fortunate thing for us. It confines in the smallest possible cavity the maximum heat which an electric arc can give us.



THE MOISSAN ELECTRIC FURNACE IN THE EDISON STATION, PARIS.

This new apparatus, which we have modified according to the requirements of experience, has permitted us to undertake the study of a whole series of simple bodies, which heretofore have been only laboratory curiosities, for the lack of sufficient means to obtain them. Among these substances is chromium, which has never heretofore been obtained in any large quantities. In order to obtain chrome steel it was necessary to prepare in a cupola an alloy of iron and chrome very rich in carbon, and known as ferro-chrome. With an electric furnace an abundance of cast chrome is obtained, by reducing the sesquioxide by means of carbon. This cast product, when refined, gives us the chromium, and this inoxidizable metal is very different from that heretofore obtained. It takes a finish like iron, and a very beautiful polish. In one experiment forty-four pounds of chromium were obtained at one casting. Molybdenum can also be obtained in the same way in large quantities. Combined with steel it takes a temper, and can be forged under the anvil at red heat.

Tungsten was a substance formerly known to chemists only in a state of powder; its preparation in the electric furnace will become very simple. Under the action of the arc the oxide of tungsten will be reduced by the carbon and will give us in a few minutes a pure metallic mass, covered with a beautiful layer of blue oxide of tungsten. The tungsten does not seem to have a great affinity for carbon, and can therefore be produced in a very pure state.

By submitting a mixture of sesquioxide of uranium and carbon to the electric heat reduction is made in a few minutes and produces a metal having a brilliant fracture and an extreme hardness, and with a slight admixture of carbon presents the curious property of igniting on con-

1. From *La Nature*.

tact with silica. All these simple metallic bodies melt at the very highest temperatures; beside them we placed other metals, whose minerals are very rare, such as zirconium and vanadium.

During these long researches we have had occasion to handle currents of greatly varying strengths. Beginning with a small machine of 4 H. P. they have been gradually increased up to machines of 100 to 300 H. P., situated in the station of the Edison Co., an illustration of which is given in the accompanying engraving, which shows the furnace placed on a table. These studies have led us to the conclusion that the heating power of the electric arc certainly increases with the intensity of the current. M. Rosetti looked upon the electric arc as possessing a constant temperature, independent of the current, and he attributed to this arc the excessive temperature of 4,800 degrees, and at the positive electrode with the current furnished by 120 Bunsen elements a temperature of about 4,000 degrees, although physicists have not yet measured this in a reliable manner. With the enormous heat given out by the arc we are very certain that we are very far from the 2,000 degrees which we obtained formerly in the laboratory.

By means of a machine of 300 H. P. titanium has also been prepared in large quantities, the properties of which are entirely different from those formerly attributed to the gray powder bearing that name. This body takes fire in fluorine, it does not decompose water except at red heat, and possesses the curious property of burning in nitrogen at high temperature, furnishing the nitrate of titanium. It combines easily with carbon and silicon, but not with argon.

I am convinced that the working of metals by means of the heat of the electric arc will be developed to a very high degree. One will thus avoid adding to the mineral all the impurities of the coal, the gangues and the fluxes will disappear, and finally one will bring to the desired temperature the mixture to be put into reaction. As an example we may mention the production of carbide of calcium, which by contact with water disengages acetylene, for the production of which works are being erected in America, England and Germany.

ELECTRIC TRANSPORTATION DEPARTMENT.

THE BALDWIN-WESTINGHOUSE ALLIANCE.

The great industrial alliance of the Baldwin Locomotive Works and the Westinghouse Electric Manufacturing Company is already at work on designs for standard equipment. It is proposed to turn out a type of electric locomotive that will be an answer to the inquiries and demands that are being made all over the country. Whether the motor trucks that will be constructed for light and for heavy service will be put under the cars will depend entirely upon the conditions in which they are used. The essential thing is to get up designs for trucks to carry the motors, which will be up to the best locomotive practice in economy of construction, safety of operation, and ease and economy of repair. When this equipment has been designed, doubtless one, or two, or three motor trucks will be built, and will be used experimentally. The companies have many requests for plans and estimates for electrical equipment of existing lines and of projected lines, and it is highly likely that they will have all they can do as soon as their standard equipment is thoroughly worked out. It is not yet learned that the contracting parties have been asked for designs for equipment for main lines of railroad, and it is doubtful whether such a request would meet with much encouragement, at all events, for some little time to come. The question of the speed of the new form of locomotive is for the present a secondary consideration. Mr. D. L. Barnes, the consulting engineer of the combined companies is quoted as saying: "What the public wants is not a high speed, for that is merely spectacular. They desire quick transit, and this is provided by a high average of speed as distinguished from a high maximum of speed."

LIGHT RAILWAYS.

Some interesting reports from British representatives abroad on the subject of light railways have just been issued says the London *Electrician*. Their publication has been delayed owing to the despatches having been placed, in manuscript, at the disposal of the committee of the conference convened by the Board of Trade to consider the question of light railways and tramways. In Belgium there are 75 such lines extending over 836 miles. Of these, six belong to private companies and the remainder to the National Society of Local Railways. Dividends have been steadily increasing. Agricultural products have certainly been benefited by the establishment of light railways, the most remarkable instance being the culture of beetroot, which has received a great impetus, and has, in turn, given rise to the establishment of a large number of sugar factories. In Prussia the light railways, or "Kleinbahnen," number 87, with a total mileage of about 480 miles. Of these the German Government says: "In general the light railways appear to be well adapted to the development and improvement of agriculture and forestry and their accessories, particularly to opening up new markets and facilitating the carriage to and fro of manure and raw produce over a considerable area of country."

The operation of roads of this class by electricity will probably be the next step in the evolution of this class of transportation.

TROLLEY LINES TO THE ATLANTA EXPOSITION.

The Atlanta Consolidated Street Railway has perfected plans for its terminal at the Wilson avenue entrance to the Exposition grounds. The station will be circular and enclosed within a circular space, the track running around in the form of a loop from the entrance to the exit. This loop will be separated from the Exposition grounds by a fence at which turnstiles will be located. Going in on the right of the loop passengers will buy Exposition tickets and pass through the turnstiles. Coming out of the Exposition grounds visitors will buy street railroad tickets and enter doors arranged successively along the platform on the left of the loop. Each door represents a car route, and this will be indicated by signs overhead; all car lines will converge on the Exposition grounds, and passengers returning can take a car for any part of the city. Below the doors of the different car routes is an exit marked "overflow" and when cars for special routes are not full, they will stop at the overflow and take passengers for the centre of the city. A terminal station similar to this one will be at the Jackson street entrance and converging on the two points cars will come from every quarter of the city.

MORTGAGE OF THE CICERO & PROVISO ROAD, CHICAGO.

A mortgage for $2,500,000 has been filed by the Cicero & Proviso Street Railway Company. It was given to the Illinois Trust and Savings bank, and is for the purpose of securing bonds. The individual bonds have a face value of $1,000, and run for twenty years, with interest at 5 per cent. per annum. About one-third of the issue, or bonds to the amount of $871,000, will be used to take up the first mortgage bonds of the road, amounting at par to $740,000. The remaining $1,400,000 of bonds will be expended in improvements and extensions contemplated.

LONG DISTANCE WORK IN CLEVELAND.

A special dispatch of Aug. 6 from Massillon, O., says: Gov. McKinley a few years ago appointed a commission to study the subject of road improvement in Ohio. The committee took its own time, and finally filed its report, which ignored the subject of road improvement, taking the ground that the age of electricity was at hand, and recommended a network of tramways, which should usurp the functions of the plodding farm horses. The report was regarded as the work of dreamers at the time, but now a project has been launched, framed upon the lines suggested in that report. The Wadsworth Electric Railway Company has been chartered to build a road from Wooster to Cleveland. It is privileged to carry passengers, baggage, express goods, United States mails and freight; to build single or double track, with all necessary spurs, switches, etc. The significance of the spurs is in this: It is designed to be a road for the public, thrown out where cars can be left for farmers, dairymen, gardeners and others to load their products, which can be run to meet any market at any point along the line, thus enabling persons within five miles of the road on either side to avail themselves of any market. In a

circular the company say: "We expect to haul farm products, hay and straw in bales, grain, dairy products, coal, dry goods, boots and shoes, clothing, etc. So it will be of value to all classes of society and for all commercial interests. It is proposed to run express cars at twenty miles per hour, accommodation cars that will pick you up and let you off anywhere, and freight cars."

THE WASHINGTON METROPOLITAN UNDERGROUND SYSTEM.

The Metropolitan Street Railway Company of Washington, has, it is claimed, demonstrated conclusively that the underground electric system is better suited to the operation of street railways than the overhead trolley. The company has been experimenting with the new system recently illustrated in THE ELECTRICAL ENGINEER, for some time, and the tests have been so satisfactory that the management has decided to change the motive power of all the lines under its control from the overhead to the underground electric system.

In a letter to Third Vice-President Spence of the Mercantile Trust and Deposit Company, Baltimore, President Phillips said that the company was operating 16 motors and two trailers on the Ninth-street line, with the underground system, and that the earnings showed an increase of about 75 per cent. Formerly the F-street and Connecticut-avenue lines furnished two-thirds of the receipts to the Ninth-street line's one-third. Now the earnings of the latter are greater than the combined receipts of the two former lines.

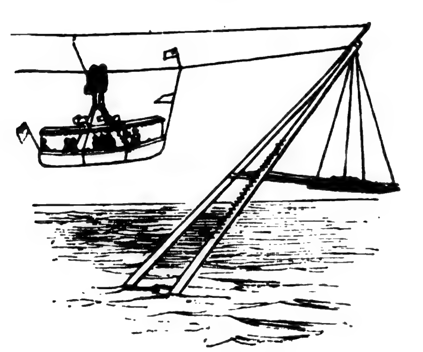
President Phillips also said that the cost of operation was less under the new than under the overhead trolley system. The work of changing the motive power on the F-street and Connecticut-avenue lines is being pushed with all possible haste.

THE DEMAND FOR HORSES.

Since I have been in the horse business, says Mr. I. H. Brockway, of Boston, Mass., there have been a great many inventions, such as electric cars and bicycles, which one would think would stop the sale of horses, but I find that my trade has increased more than 50 per cent. in the last three years, and there have been more horses sold in Boston in the last year than ever were sold in one year before. Why? Because the horse has been sold more cheaply, and more have been used for pleasure, both under the saddle and harness, and for heavy draught work. And, in my opinion, good horses will be worth twice as much in two years as they are now, because the farmers in the West, where they are raised, have got the idea that they would not be worth raising.

AN AERIAL TROLLEY BOAT.

THAT paradise of popular amusements, West Brighton, Coney Island, has this year added to its attractions an electrically propelled boat. But the novelty of the arrangement consists in the fact that the boat does not travel on the water but over it. The arrangement is shown in the accompanying engraving. As will be seen the boat is suspended from a cable, 825 feet in length, which extends out some distance into the water, being supported by shears at both ends. The shears at the seaward end of the line are inclined outwards at an angle and to help counteract the strain of the cable on them a weight of five tons, consisting of



THE AERIAL TROLLEY BOAT AT CONEY ISLAND.

bags of sand upon a platform, is suspended from their highest point. In the rear of the shore end of the line is a building containing the dynamo that supplies the necessary power, and from the cable hangs a 10-horse-power motor. Beneath the motor swings the boat in which the passengers sit.

In the regular trip of the trolley the boat is carried just high enough to clear the spray of the breakers, and a pause of a few minutes is made at the outer terminus to give the passengers a view of sea and shore from their unique position.

THE TONAWANDA WALKING ELECTRIC MAN.

ELECTRICITY has been called upon in innumerable ways by the enterprising advertiser to catch the eye of the public, and invariably with success. It has usually been employed for obtaining spectacular advertising effects, but the latest electrical device employs it as a motive power to drive a vehicle apparently propelled by a man. The accompanying engraving illustrates

THE TONAWANDA ELECTRIC MAN.

the show wagon built by Messrs. Gillie, Godard & Co., of Tonawanda, N. Y. The wagon is seemingly pulled along the street by the dummy in livery who raises his feet and imitates all the motions of a person walking. Inside the wagon is a motor driven by a storage battery. A sprocket and chain gears to the wheels, and a link movement attached to the dummy's hips imparts the walking motion to his legs. The "electric man" on his rounds has attracted much attention in Tonawanda.

TWO MORE STEAM LINES TO BE ELECTRIFIED.

The Whitefish Bay railroad, Wisconsin, will be changed from a steam or "dummy" line to an electric line early next year, by the Milwaukee Street Railway company.

The Lutheran steam line of the Brooklyn Heights Railroad company, running between Ridgewood and Lutheran cemetery, Brooklyn, has been changed to an electric line and hereafter cars will run more frequently, giving better service to the public.

ELECTRIC RAILWAY RETURNS IN ROCHESTER, N. Y.

The report of the Rochester Railway Company for the quarter, ending June 30th, has been filed. The report shows: Gross earnings from operation, $220,167.02; operating expenses, $127,096.98; net earnings from operation, $93,070.04; income from other sources, $1,536.66; gross income from all sources, $94,606.70.

The report for the same quarter of 1894 showed: Gross earnings from operation, $179,969.47; operating expenses, $104,042.69; net earnings from operation, $75,926.78; income from other sources, $1,949.98; gross income from all sources, $77,876.76.

SALE OF THE ST. JOSEPH, MO., TROLLEY AND LIGHTING PROPERTIES.

A SPECIAL dispatch of August 22 from St. Joseph, Mo., says:—The St. Joseph street railway lines, together with all the rolling stock, real estate, and other property used in their operation, and all the property of the St. Joseph Traction and Lighting Company, were sold at public auction yesterday and were bid in by E. A. Noyes, of Portland, Me., and Edward P. Harrigan, of New York, purchasing trustees of the stockholders of the company, for $800,000, which was the lowest bid that could be accepted under order of the court. The sale was made to satisfy a mortgage held by the Central Trust Company of New York.

MODEST TROLLEY FIGURES IN PHILADELPHIA.

Messrs. L. H. Taylor & Co. of Philadelphia issue a special circular on the street railway consolidation in that city. The Union Traction Company now owns and controls about 420 miles of street railway and is capitalized, including the constituent companies, for $41,410,600 funded debt and $87,891,000 stock, of which $21,000,000 is placed in trust. Fixed charges, less rentals received, are estimated at $5,889,400 a year. The calculation of dividend prospects place operating expenses at 50 per cent.

THE West End Street Railway Company has contracted with the American Electric Heating Company to equip 750 of its 889 cars with electric heaters, the work to be finished by Nov. 1.

LETTERS TO THE EDITOR.

LOSSES IN HYDRAULIC ELECTRIC RAILWAY GEAR.

On behalf of one of my clients I should like to ask what the Dey-Griswold Company do with the heat generated in their hydraulic gear described in your journal of August 7, on page 180 and commented on in your editorial column. All the lost mechanical energy (due to the torque of the motor multiplied by the difference in speed of the motor and the driven parts, at starting, or at slow speed) is necessarily converted into heat, and I am informed that practical experience has shown that apparently all of this energy is transformed into heat generated in the liquid, whether oil or water, as it is forced through the hydraulic gear. Indeed, it is hard to see how else to account for this lost power.

About three or four years ago there was an interference proceeding in the Patent Office on a gear substantially identical with that shown in the drawings in the ENGINEER, and if I remember correctly *fourteen* "original inventors" contended over the invention. The thing was thought to be of great value at the time, but for the excessive heat generated. If the Dey-Griswold Company will give the public the benefit of their experience in this matter, it will, I think, be of considerable interest to engineers, and especially so to me.

HAROLD BINNEY.

In reply to the above communication of Mr. Harold Binney I will say that Mr. Binney's client does not seem to understand the principle of the system he is criticizing. He has confounded it with the shunt liquid devices which have been patented by numerous inventors and experimented with by at least two large electrical concerns. I thought of the same device before inventing my present system and passed it by as impracticable. I appreciated the force of Mr. Binney's objections without spending money to obtain a hind-sight at it.

If Mr. Binney will look a little deeper into the principles of our system he will see that the torque varies inversely as the speed, so that the product of the two are always equal. The mechanical efficiency is slightly higher at slow speed, due to the slower speed of the fluid.

I would like to quote the following from a letter written by Prof. W. A. Anthony and published in THE ELECTRICAL ENGINEER, of Feb. 20, 1895:—

"It would be a great gain to electric transmission for railway work if some thoroughly efficient and reliable means could be devised for maintaining the high efficiency of the motor while running the train at varying speeds. This must be done either by changing the counter E. M. F. of the motor or by a gearing permitting of variation of the speed relations between motor and axle. It must not be done by introducing resistance to lower the speed of the motor or by any frictional device or shunted liquid gearing where energy is wasted in friction. Most of the devices proposed for varying the speed relations between motor and car axle have been open to this objection. One method proposed, I am not sure that it was ever tried even experimentally, is theoretically correct, but perhaps might not prove successful in practice. It consists in connecting the electric motor to the car axle by liquid gearing, there being several liquid motors on the car axle through one or more of which the liquid put in motion by a pump driven by the electric motor, could do its work. When all the liquid was forced through one motor a high speed would result, when it was divided between several motors the speed would be slow, but the efficiency of transmission would be as high for the slow speed as for the high."

The principle so favorably spoken of by Prof. Anthony is the same upon which we are working, with the exception that the variable capacity is in the pumps. I was working on the identical thing last winter and I think a friend of mine called Prof. Anthony's attention to it. The present method is a great improvement, as it does away with all steps and dispenses with the numerous valves, especially the reversing ones which were cumbersome.

I first thought of the variable pump idea in 1890 and constructed a complete working model, one-eighth size, having a pump with three compartments having capacities relative to each other as one, two and four. With this I could obtain seven different speeds by short circuiting various combinations, letting the balance do the work. This had the disadvantage of running idle pumps the greater portion of the time, which the present system does away with. Oil is an incompressible fluid and there is no excuse except poor designing or workmanship for having a hydraulic system heat.

I have made an exhaustive study of this subject during the past five years, and have consulted with the best hydraulic engineers, and the more I dig into the facts the more my faith increases. There was a time when it was not considered possible to run a dynamo without keeping a stream of water running through it. That same remark in the past tense will be applied to the liquid transmission of power before many years.

HARRY E. DEY.

NEW YORK, Aug. 17, 1895.

THE SUPERIORITY OF THE DIFFERENTIAL ARC LAMP.

REFERRING to the articles of Mr. E. R. Knowles on "The Shunt *vs.* the Differential Arc Lamp" in your issues of June 26 and July 3, I beg to call your attention to a pamphlet of mine entitled "On Arc Lamp Circuits," (Hans Paul, Leipsic, 1894), in which this subject is treated mathematically and in detail. I have also arrived at the result that the differential lamp is always to be preferred.

DR. LUXENBERG.

DRESDEN-TRACHAU, GERMANY, July 28, 1895.

SPEED OF ELECTRIC LOCOMOTIVES.

IN a recent article which appeared in THE ELECTRICAL ENGINEER, Mr. Robert S. Ball agrees with Mr. H. G. Prout in saying "that an electric locomotive has not yet been made that could outrun the steam locomotive"; but he contends that if "they are to build engines of either type to pull trains at a higher speed than at present, the electric locomotive will be selected for that duty."

I beg to call the attention of both gentlemen to Mr. Oscar T. Crosby's article in THE ELECTRICAL ENGINEER of July 17, on "The Problems of Electric Railway Work," in which he claims the electric locomotive offers an advantage over the steam locomotive at very high speed. The maximum recorded speed of a steam locomotive with train is 112 miles per hour, while that of an electric motor is 120 miles an hour made under Mr. Crosby's personal supervision. I trust the gentlemen in question will read Mr. Crosby's article.

D. E. WHITING.

CHICAGO, ILL., Aug. 16, 1895.

IN justice to the gentlemen referred to by our correspondent, and not less to Mr. Crosby himself, it is well to point out that the article which appeared in our issue of July 17, as there stated in a foot note, was an interesting interview had with Mr. Crosby by the untechnical reporter of a daily newspaper. Hence certain allowances must be made on technical points. The electric locomotive which Mr. Crosby refers to as having attained a speed of 120 miles an hour was entirely experimental in its nature, carried no passengers or motorman, and indeed consisted practically of little more than a narrow gauge truck, upon which the motors were mounted and enclosed in a cigar-shaped housing. Mr. Crosby was careful to say that the speed was "made experimentally," but it would seem that the reporter's phraseology referred to may have been slightly misleading.—EDS. E. E.

VIOLATIONS OF FIRE UNDERWRITERS' RULES IN NEW YORK.

As consulting engineer I desire to enter a most emphatic protest against the outrageous manner in which the electric light equipment is being placed in position in the new buildings to be occupied, when finished, by the St. Luke's Hospital. The work as far as completed is absolutely in violation of the rules and regulations of the New York Board of Fire Underwriters, and not only that, but the manner in which the work is placed in position is such that the electric light interests of this city will be greatly injured owing to the fact that there will undoubtedly be constantly more or less trouble with the equipment, and naturally the electric lighting interests will be criticised, and the blame not placed upon the proper parties.

For the information of your readers, who are not acquainted with the facts, the undersigned would state that the wiring as originally commenced was single brass armored conduit work, it being designed to use twin wire within the conduits. This work was immediately condemned by the undersigned, acting for the Bureau of Electrical Inspection, and it was also condemned by Inspector Forsythe of the New York Board of Fire Underwriters, but for some unaccountable reason the New York Board, through its representatives in the Survey Department, went over the inspector's head and passed the work and allowed the contractors to proceed.

Not satisfied with placing single brass armored conduit in position, the contractor has lately resorted to Circular Loom tube, and is drawing in twin wires. The manner in which the Circular Loom tube is placed in position is such that an inspection made recently showed that the tube has been placed under radiator coils, buried in cement, placed outside of cement, alongside steam pipes, across steam pipes, over iron girders, around the edges of iron girders, run crosswise over cement floors, and said tube (by digging up portions of it) was found flattened or crushed by being struck with mechanics' tools, and thereby rendered practically useless as a conduit,—to say nothing of the fact that it is but a question of time when the insulation upon the twin wires is liable to give way; and although no fire may be caused to the building, there will be an interruption of the electric light service, which can only be repaired by running wires upon the outside, as anyone who has seen the manner and methods employed in this particular installation knows that it is a physical impossibility to

withdraw the twin wires from the single Circular Loom tube, as placed in position.

In two cases it was also noted that Circular Loom tube has been pieced out with brass armored tube. In the first place it should be noted that such work would never have been contemplated nor placed in position if it had not been for the peculiar action on the part of the New York Board. Why they acted as they did is beyond comprehension. The indisputable facts are, however:

1. The installation has been placed in position in violation of the standard rules of the Underwriters, and by their consent.

2. It has been placed contrary to the usual practices that are employed in high grade work, such as the authorities in charge of the erection of this building certainly expected to get.

The equipment is in, or more than three-fourths of it, and what are the authorities going to do about it? The writer hopes that this communication may be the means of calling for an investigation of the statements made above, and the blame placed where it belongs. In a building of this character there should not have been the slighest hesitancy as to the best methods to be employed, and *iron armored conduit*, which is, up to the present time, the best form of construction work that can be recommended, should have been placed in position.

FREMONT WILSON.

NEW YORK, Aug. 23, 1895.

LITERATURE.

Special Agents' Electrical Hand Book. By A. M. Schoen, New York; 1895. The Spectator Co. 113 pp. 4 x 6 inches. Flexible covers. Price, $1.

This little work is intended more particularly for the guidance of insurance inspectors, showing them where to look for defective work, and pointing out methods to be employed in electric wiring work, and the general erection of electrical machinery in isolated plants. It ought to prove a handy little pocket companion for the insurance inspector.

Practical Directions for Electric Gas Lighting and Bell Fitting for Amateurs. (Third Edition.) By E. Trevert. Lynn, 1895. Bubier Publishing Co. 62 pp., 4½ x 7 inches. Paper. Price, 25 cents.

Cours Elémentaire d'Electricité By B. Brunhes. Paris, 1895. Gauthier-Villars & Fils, 265 pp., 5½ x 8½ inches. Paper. Price, $1.40.

Electricity in our Homes and Workshops. By Sidney F. Walker. (Third Edition, revised.) New York, 1895. D. Van Nostrand. 346 pp., 5 x 7 inches. Cloth. Price, $3.

IN the present edition the author has largely added to his chapter on telephones, describing the latest forms of apparatus. A short chapter has also been added on dry batteries.

National Electric Light Association. Report of the 18th Convention held at Cleveland. New York, 1895. The James Kempster Printing Co. 269 pp., 6 x 9 inches. Cloth.

ALTHOUGH not quite so bulky in volume as some of its predecessors, this report contains much that is of permanent value both in the papers and in the discussions to which they lead. The frontispiece is a good portrait of past president M. J. Francisco.

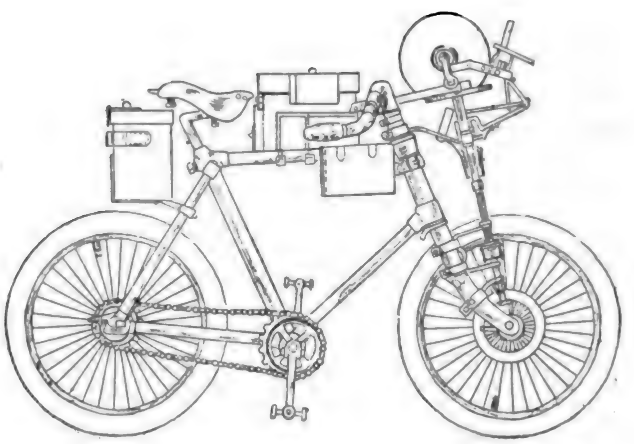
COMMENTS ON THE DATA SHEETS.

Mr. Paul Lupke, the electrician of the Trenton, N. J., Electric Light & Power Co. favors us with the subjoined interesting comment on THE ELECTRICAL ENGINEER Data Sheets:—"I am taking great interest in the Data Sheets and I am patiently waiting for more. May I offer a suggestion? Would it not be well to print the data of issue on each Sheet instead of over the top of them? You know very well that electrical data do not improve with age, and that in most cases it is of great value to know the time at which the data were considered correct. To the Sheets you have issued so far I have added a number of blanks, properly numbered according to your index and filled up with data from current literature. I am inclined to think that many of your readers would feel obliged to you for the issue of some blank sheets. This would afford an easy and comfortable way to lay hold of stray bits of information, which we run across now and then, and do not know just where to put to have them handy when needed. No doubt many of these temporary sheets would in time be replaced by your regular ones, but in the mean time they will certainly serve a good purpose. Enclosed find 60 cents for which you will please send me one of the filing cases."

NEW SIGNAL SERVICE BICYCLE.

The U. S. army signal officers have equipped the service with an ingenious arrangement for distributing telegraph and telephone wires. It was found that in laying insulated or naked wire on the ground preparatory to establishing communicating stations, the weight of the reel containing the wire was considerable, and it had to be carried on a handcart. This arrangement required two men in the operation—one to push the cart, the other to wind and unwind the wire. The latest method is to carry the wire on a reel which is fixed to a bicycle. The rider, by his propulsion of the wheel, distributes the wire in the track of the machine. An ingenious mechanism also permits him to rapidly gather up the wire from the ground, and it is reeled on a spool borne in front of the handle bar.

This use of the bicycle is a great saving of labor and time, and will be of great value on the battlefield, when the rapid construction of communicating lines is of great importance. In front of the saddle this Signal Corps bicycle will support a case of instruments and tools, in addition to the usual leather pocket in which the bicycle implements are carried. Supported over the rear wheel of the machine, and directly behind the saddle, is the case which contains the telegraphic and telephonic instruments. This can be removed, and a communicating station established anywhere along the line.



A SIGNAL CORPS BICYCLE.

This bicycle has been tried with much success in Texas, and it will be adopted generally by the signal linesmen. The bicycle will probably relieve the corps of much travel, and its lightness, even with the reel of wire and instrument cases, readily permits its being lifted over obstructions, such as stone walls, hedges, and fallen trees. It will enable the operators to work with speed, both in laying and in gathering the lines of wire. The reel will carry insulated as well as naked wire, experiments with the latter having proved that it is also of much value.

GROWTH OF THE NORTH AMERICAN TELEGRAPH CO.'S SYSTEM.

THE North American Telegraph Company has taken complete charge of the commercial business done over the telegraph wires of the Soo line. Though closely related heretofore, the two companies have maintained separate offices in Minneapolis, the Soo telegraph business being attended to at the office of the company in the Guaranty Loan building, that city. Speaking of the new arrangement, H. A. Tuttle, general manager of the North American, says: "This is a decided advance for our company and puts us in better shape in several ways. We now have direct control of all the commercial business on the Soo lines for a distance of 1,200 miles altogether. There are, of course, no large places on these lines, but there is a considerable amount of business originating along the system. We also get the benefit of a direct line into Winnipeg by virtue of an arrangement with the Canadian Pacific from the international boundary. The lines of the North American proper include about 600 miles from Chicago through Minneapolis to Duluth. By connection with the Postal Telegraph Company at Chicago we reach every part of the world."

Mr. Tuttle intimated that this move of the company was the beginning of a policy of extension of its lines and interests through the Northwest. There are many good towns that would welcome a new company, and which it will be policy for the North American to reach.

C. M. Loring, president of the company, said that the move was better for the Soo line than for the North American, and that the recent extension of the Postal Telegraph lines to the Pacific was the most important advantage which had accrued to the company of late.

SUPPLEMENT.

IS TELEPHONY TRIUMPHANT?

WE have the pleasure of presenting to our readers in this issue the full text of what must forever be regarded as one of the most important of the fundamental documents relating to and governing the development of both telegraphy and telephony in the United States, namely, the famous agreement of 1879 whereby the Western Union Telegraph Company, then an active competitor for the business, retired from the telephonic field, while in consideration of being left in full possession of the new domain the American Bell Telephone Company agreed to pay the handsome commission of 20 per cent. on its rentals or royalties. The document is full of interest at this juncture, when, as we show elsewhere, the telephone is everywhere parelleling the longer telegraph lines that yield the bulk of telegraphic income, and when it would appear that new adjustments to changed conditions must necessarily be in order.

Some of the daily papers have, we regret to note, presented seriously erroneous statements in regard to this famous document, and we are glad therefore to do the public service of setting matters right. It was hardly to be expected that either party to the agreement would go out of its way to correct the misstatements made; but as the document is, so far as we can form an opinion, creditable to the pacific intentions of both of them and exhibits the remarkable foresight of those who concluded it was better to enjoy a large income than to squander it on litigation, we think we may hold it up as an example that often might be followed most advantageously in electrical and other work. The ruination of many branches of electrical industry has been the frantic legal fighting in them and the destructive lowering of prices; but here we have clear evidence of a better way of doing things. It is obvious, also, that as an alternative to fighting or to consolidation, an agreement of this nature has many recommendations. The Western Union found it so in this case. We see, for ourselves, no ground for regret on its part, any more than we see any for regret as to its agreement with the Postal Telegraph-Cable Company to maintain rates at a living figure. The telegraph interests are subject like all others to the effect of new habits among the people, and must rise or decline in the long run as circumstances and events modify the environment; but skillful diplomacy will remedy many evil situations and not only find compensation for loss but new channels of unsuspected profit.

An agreement is essentially something to differ about, and hence it is not surprising that this famous document should itself have needed elucidation and interpretation. Some years ago, the Western Union Co. was understood to be seeking payment from the American Bell of moneys not nominated in the bond as rentals but which might bear that character. The final upshot of that contention has not been made known, so far as we are aware; the case even now, in some shape, may be slumbering quietly and conveniently on some court docket. Another point is the consent of the American Bell Company not to allow news matter to go over the telephone wires. For a long time past this has not been lived up to, but disregarded in a way of which the Western Union must be well aware.

For example there lies on our desk at this moment a late telephonic dispatch from New York in one of the Philadelphia daily papers, of no less than 55 lines, with a bold heading announcing the means of its transmission. One constantly sees such dispatches in the daily papers.

The date of expiration of this important contract is a matter of no little interest. According to Article 17, the contract would nominally expire seventeen years from the first day of November, 1879, but its continuance and further operation might well depend upon the Berliner patent, which has now become a football in the courts, but which as a means of sustaining monopoly fits neatly into the space left vacant by the expiration of the Bell fundamental patent named specifically in Article 2, section 8.

Triumphant Telephony is an idea that has seized upon many minds, but we can in no wise bring ourselves to believe that the telegraph is a defeated art or that when worsted it is to disappear off the face of the earth. It may be more sharply limited than it once was, but its future, to our eyes, is bright for usefulness, great and growing as the scope of telephony has now proved to be. The contrast between the relations in 1879 and those in 1895, as presented by our issue this week, is one of the most striking that electrical applications have ever shown. To-day our population averages barely over one telegram per head a year, while telephonic messages are more than ten times as numerous, the figures being in round numbers, respectively 75,000,000 and 750,000,000. Every twenty four hours the telephone is now used more than two million times, so that, broadly, four million people, or about 25 per cent. of the adult population, use it daily. Yet there was little prospect of such growth or of the infinite development now beginning under freer conditions, when the Western Union closed up or turned over its numerous telephone exchanges, and settled down to its own branch of the intercommunication industry.

IS THE PRESENT TYPE OF CENTRAL STATION DOOMED?

Dr. d'Arsonval, who easily ranks first among electrophysiologists of France and who is recognized as an authority the world over, has just concluded a series of experiments on the electrical activity of the torpedo, technically known as the *raia electrica*, which are of such transcendent interest that we have devoted a page to recording them. Dr. d'Arsonval's researches have shown conclusively that the current effects obtainable from the torpedo are far beyond what had ever been thought possible, and as a result they have a bearing on the work of the electrical engineer which must command immediate attention.

If, as Dr. d'Arsonval has shown, an able-bodied electric torpedo can be depended on to give 7 amperes at 17 volts its utilization for central station and isolated plant work must suggest itself at once. Thus, taking for example, a 5,000 lamp station, all that would be required would be about 2,500 amiable fishes, grouped seven in series to give 119 volts, and 357 in parallel. With a reliable and automatic method of pinching the fishes there ought to be no difficulty experienced in regulation; and lamp breakage from this cause ought to be insignificant. The small cost of installing a fish tank and the low rate of maintenance and fish food, as compared with the complication of boilers, engines, dynamos, coal expense and attendance, now required to generate current, leaves no question as to the superiority of the fish central station. Then again, with each fish capable of giving out 119 watts it would require only a fraction over 10 fishes to maintain twenty 50 watt lamps, a number sufficient to light the large majority of private houses. If the objection be raised that the fishes get tired after a while, it is a simple matter to have two or three sets installed and switch them on to the circuit successively, by means of the Pennock volt-distributor. Indeed, the more we examine into this subject the more we are convinced that in the direction of animal electricity lies the most promising opening for the future of lighting and that the electrical profession is under heavy obligations to Dr. d'Arsonval for pointing out the way of progress. As we go to press, the news reaches us that torpedo roe has gone up several hundred per cent. in price in consequence of a corner in the market.

CONDUIT ELECTRIC RAILWAYS.

There are not many conduit railways in this country, but the mileage that is actually in operation appears to be doing pretty well. The reports from Washington now are that, encouraged by its first success, the Metropolitan Company will untrolley some of its lines and put in more conduit. If true, this is decidedly important. In New York City, the conduit road uptown of the Metropolitan Traction Co. is doing remarkably well, and several of the cars are now hauling trailers. One disagreeable feature of the system appears to be the frightful dust accompanying the passage of the car. The swift movement of the car above the slot, and, perhaps, the construction of the conduit, sets up a small cyclone, and the clouds of dust at some points, each time a car goes by, are startling in their volume and density. We have never seen a trolley car or a cable car make itself quite so obnoxious in this respect; but the evil is assuredly possible of correction.

INDIRECT ELECTROLYSIS.

M. Andreoli has described in *Le Génie Civil* an experiment on direct electrolysis. Taking a cell divided into three compartments by porous diaphragms, a solution of any salt is placed in the central compartment, whilst the two electrodes are placed in the side compartments immersed in similar or different electrolytes. The decomposition of these latter is, on the current being passed, effected as if the central compartment did not exist, the solution in it being unaffected. In this form the experiment is an old one, but M. Andreoli finds that if a plate or series of plates is placed in the solution in the central compartment, reactions occur which can only be attributed to an indirect or secondary electrolysis. If, for example, the two outer compartments are filled with a solution of common salt, and the central one with a solution of cyanide of gold; let the anode in the one compartment be of carbon, and the cathode in the other of iron. On passing a current under these conditions chlorine is evolved at the carbon electrode, and caustic soda produced at the other, the cyanide solution being, as aforesaid, unaffected. If, however, whilst the current is passing, a series of metal plates are immersed in the cyanide solution, the gold is deposited on them, though neither chlorine nor soda appears to pass into the central compartment.

TELEPHONY.

THE AMERICAN BELL AND WESTERN UNION AGREEMENT OF 1879.

FIRST AND FULL PUBLICATION OF THE EXACT TEXT OF THE FAMOUS COMPACT OF 1879.

SUBJOINED is given the full text of the famous agreement of 1879, between the American Bell Telephone Co. and the Western Union Telegraph Company, by which the former agreed to pay the latter a commission of 20 per cent. royalty on its telephone rentals and the latter agreed to abandon its existing exchanges and abstain from all telephone business. This agreement nominally terminates, as will be seen, in November, 1896. It should be studied in connection with the article in this issue of THE ELECTRICAL ENGINEER on the remarkable development of the long-distance telephone system as a formidable competitor for business hitherto going over the telegraph wires.

THIS AGREEMENT, MADE THIS TENTH DAY OF NOVEMBER, 1879, BY AND BETWEEN THE *Western Union Telegraph Company*, FOR ITSELF AND FOR THE *Gold and Stock Telegraph Company*, *American Speaking Telephone Company*, AND *Harmonic Telegraph Company* WHICH IT REPRESENTS, PARTY OF THE FIRST PART, AND THE *National Bell Telephone Company*, PARTY OF THE SECOND PART, WITNESSETH:

ARTICLE 1. (1.) The party of the second part shall pay to the party of the first part, upon all telephones used in the United States, under any license from the party of the second part, express or implied, unless expressly excepted, a royalty or bonus of twenty per cent. of all rentals or royalties actually received or rated as paid in accordance with the provisions of this contract, from licenses or leases for speaking telephones (exclusive of call bells, batteries, wires, and other appliances, or services furnished or performed). The rentals or royalties upon which said royalty or bonus to be paid to the party of the first part is to be reckoned, shall, for that purpose, be ascertained by deducting from the gross rental or royalty received or rated as hereinafter declared, the commissions and allowances herein provided for.

(2.) The royalty or bonus to be paid on telephones made in the United States solely for export and not licensed for use in the United States, shall be twenty per cent. of the net profit actually derived by the party of the second part in their manufacture and sale above the cost of such manufacture, not including any part of the general expense of the party of the second part as part of such cost, and not including in the manufacturer's profit any enhancement of price fairly due to the fact that the party of the second part holds or in any way controls a monopoly of the use of such telephones in any foreign country other than Canada, if such case shall exist.

Provided, however, that where the party of the second part shall be in any way interested in the purchase or use of such telephones in such foreign country, it shall be at the option of the party of the first part to require an accounting for all telephones so exported as if sold at a fixed profit of thirty-three and one-third per cent. upon the cost of manufacture.

(3.) Allowance shall be made for rentals or royalties which cannot be collected, and for usual and reasonable deadhead or free privileges.

ARTICLE 2. Concerning the sum which is to be taken as the gross rental or royalty for the purposes of the preceding article, it is declared and agreed:—

(1.) The word "telephone," as used in this contract, refers to an instrument for electrically transmitting or receiving articulate speech, and is understood to mean either a transmitting instrument incapable of use as a receiver, a receiving instrument incapable of use as a transmitter, or an instrument capable of being used both as a transmitter and receiver.

(2). Ten dollars per annum for each telephone where only one is used at a terminal or station, and fifteen dollars per annum for a pair of telephones composed of an instrument used for sending and another instrument used for receiving, used at one terminal or station, are recognized as the present standard rates of gross rentals or royalties; and the party of the second part may change them, subject to the qualifications of section (4) and (5) of this article, but not otherwise.

(3.) Telephones used on exchanges or lines owned in whole or part by the party of the second part, or by auxiliary corporations or organizations in which it is interested, or rented together with lines owned in whole or part by it or by auxiliary corporations or organizations in which it is interested, shall be rated as paying to said second party the said recognized standard rates, or such other rates as may hereafter be established in accordance with this contract for like uses by parties other than the second party or auxiliary corporations or organizations in which it is interested, less the commissions and allowances provided for by this contract; but whenever the party of the second part is or shall be interested with others in the ownership of such exchanges or lines, the annual rental or royalty actually charged to and received from the owners thereof for the use of the telephones, if greater than the rates established as aforesaid, shall be taken to be the gross rental for the purpose of ascertaining the stipulated bonus or royalty.

(4.) No reduction from the present recognized standard rates which shall be made on telephones used on exchanges or lines owned in whole or in part by the party of the second part or by auxiliary corporations or organizations in which it is interested, or rented together with lines owned in whole or in part by it, or by auxiliary corporations or organizations in which it is interested, shall operate to reduce said royalty or bonus to be paid to the party of the first part below $1.00 per annum for each terminal single telephone, and $1.80 per annum for each terminal pair, unless such reduction be made with the consent of the first party, or as provided in the following section.

(5.) Whereas it is difficult to determine absolutely and in advance the price which at all times and for all purposes it will be advantageous for the interests of the patents and of both the parties as interested in income derived from royalties and rentals, to charge, either with a view of increasing the revenue of the parties hereto from royalties and rentals by enlarging the demand for the instruments, or under circumstances of competition, it is agreed that the party of the second part, in cases where its power to reduce is qualified as hereinbefore expressed, may reduce the rentals either generally or for a particular purpose, or a particular locality, or a particular licensee or class of licensees, to such sum as may be advantageous as aforesaid for the interests of both parties and as may be determined by agreement of the parties hereto, or as provided in this article. If the parties do not agree as to the propriety of such a reduction, or as to the amount, extent or manner thereof, then said second party may in writing notify the first party of its desire for a reduction, and shall specify in such notice the reduction it desires and the character thereof, and the reasons therefor, and request the other party to join with it in selecting and appointing three referees. If the parties hereto shall not jointly appoint three referees within seven days from the receipt of such notice, then the moving party may, within seven days after the expiration of said first period, name one referee and notify such appointment to the other party, and request it to appoint another referee within seven days after receipt of notice of such appointment. If said other party shall not appoint a second referee within said period, then the moving party may give to the party in default written notice of the former application and notices, and that the time therein specified has expired, and that the moving party has not received information of the appointment of a referee by the other in accordance therewith, and inclosing copies of said former notices, and the party of the first part within one week after receipt of the last described communication, may in writing appoint a referee and notify such appointment to the other party, and thereupon the reference shall be proceeded with as herein provided; and the change specified in the notice first given as above shall be deemed agreed to, and shall *ipso facto* take effect and be established upon the expiration of the period last above referred to, unless the other party shall appoint a referee as aforesaid within said period. Said two referees shall jointly select and in writing appoint a third within ten days after the appointment of the second of said two. If said two do not select and appoint a third within the period above specified, then the moving party may apply to any Judge of the United States Circuit or District Court in the cities of Boston, or New York, or Brooklyn, and request him to appoint said board of three referees. Said judge shall not be required to and shall not consider whether any occasion or right to such reduction exists, and he shall act summarily in appointing said three referees, having first given the parties reasonable opportunity to be heard on such notice as he shall think fit. If any judge applied to shall decline to act, then the moving party may apply to some other of the persons above designated. All the three referees, however appointed, shall be disinterested, and not officers nor in the employ of any of the parties named in this contract. An award in writing, made and signed by any two of them shall stand as the award of the board. Unless the decision is made and notified to the parties within thirty days from the appointment of the three referees, the moving party may, at its option, treat the reference as void and inoperative, and a new appointment may be called for in the manner and with the effect herein specified. Said referee shall have power to determine whether occasion for a reduction exists for the reasons stated in the preamble of this section, and if so, then to determine how far, to what extent, and for how long the said limitation on the power of the second party to reduce the rentals shall be removed or modified. After such removal or modification the said limitation, as modified, unless and until further changed as herein provided, shall stand and be in all respects in lieu of that hereinbefore declared. During six months after a decision so made, no new reference upon the same subject before submitted can be asked for; but during that period either party may apply to the same board of referees, and said board, if it shall find that a new state of facts, or new exigencies

have arisen and require some change, may make such change in their award as they find occasion for as aforesaid, and such change shall stand and be operative from the time it is made and notified to the parties until further change be made by said board within said period, or by a new reference called for after said period, or by agreement of said parties. If during said period any arbitrator dies, refuses, or for any reason is unable to act, then the vacancy shall be filled by said parties jointly, if they agree, and failing to agree, then by the two remaining referees, and if they do not so appoint within ten days after a request in writing from either party so to do, then the vacancy may be filled by some judge, as hereinbefore provided.

Twenty per cent. of the expenses and compensation of the referees shall be paid by the party of the first part and eighty per cent. by the party of the second part unless the referees shall otherwise order. The notices herein required to be given may be given to the President or Secretary of the Western Union Telegraph Company or persons acting as such, and to the President, Secretary or Treasurer of the National Bell Telephone Company or of its successors, or persons acting as such officers.

It is however expressly agreed and further provided that the party of the first part, at any time after the receipt of actual notice of an actual reduction of rates in consequence of its default, as aforesaid, may in the manner above provided, on alleging and showing to the party of the second part, and upon their failure to join in a reference, as aforesaid, then upon showing to any of the judges above referred to that it did not receive and was not informed of the notices to appoint and the communication of such notice, above described, require and obtain, in the manner above provided, the appointment of a reference to consider any reduction thus fixed by default, and the referees thus appointed may, by award, in whole or in part, restore the former limitation on the power to reduce rates, which restoration shall take effect from the date of said award.

If, from any cause, a reference twice called for shall fail to produce a valid determination as herein contemplated upon the matter submitted or to be submitted, then the party aggrieved may have such relief or protection in a court of law or equity in the premises by a specific performance or otherwise, as such court can afford.

(6.) Telephones for speaking-tube purposes, that is, instruments to be used for speaking from one part of the licensee's premises or from one of his buildings to another analogous to the use of speaking tubes, or telephones to be used by institutions of learning for scientific purposes, or telephones for connecting persons and families for social or household purposes only, not connecting with any exchange or central office; and telephones which are not to be used in circuit with any exchange or central office, and are not rented together with lines owned by the party of the second part directly or indirectly or by any auxiliary organizations in which it is interested, may be put out either at lower rentals than the standard, or at a gross sum to be paid in one payment, according to the discretion of the party of the second part; and in respect of such telephones the royalty or bonus is to be twenty per cent. of the reduced rental or gross sum, less commissions actually paid as herein provided.

(7.) The party of the second part may increase the established annual rate either generally or upon telephones used for any particular purpose, or by any particular class of licenses, from time to time at its discretion, and such higher rates, while in force, shall be taken to be the gross rentals or royalties in respect of the telephones for which they are obtained.

(8.) The limitations on reductions herein contained shall not apply after the expiration of the patent of the United States No. 186,787, granted to Alexander Graham Bell, January 30, 1877, which patent will expire January 30, 1894, unless some other patents owned by the said party of the second part, or under which it has exclusive licenses, shall operate to control the use of all speaking telephones substantially as they are now controlled by the patents represented by the two parties hereto.

ARTICLE 3. (1.) In ascertaining rentals on which the royalty or bonus is to be paid to the party of the first part, there shall be deducted from the gross rentals the following commissions and allowances:

On telephones used in district or exchange systems owned in whole or in part by the second party, or by auxiliary corporations or organizations in which it is interested, an allowance or commission of thirty per cent.

On telephones taken by the first party for private lines as hereinafter provided, or used by the second party on its own lines or put out by it, by its own officers or servants for any use other than on district or exchange systems in which it is interested as aforesaid, twenty-five per cent.; and the party of the first part or those it represents, shall be allowed said abatement of twenty-five per cent. from the standard rentals upon telephones leased to it or them, except where contracts heretofore entered into by said party of the second part oblige it to pay such rate, or a higher rate of commissions to its present licensees.

Upon all telephones other than the foregoing, such rate of commission as shall actually be paid, not to exceed forty per cent., except so far as existing contracts may call for higher rates.

ARTICLE 4. (1.) The party of the first part shall bear and pay twenty per cent., and the party of the second part eighty per cent. of all reasonable legal expenses incurred in ascertaining, investigating and determining, and in prosecuting and defending rights which the party of the second part may have, claim, or wish to acquire, pertaining to telephones or the right to use telephones, or to inventions used in telephones, and concerning patent rights which it or others may claim respecting the same, including expenses in suits and in proceedings in the Patent Office relating to such rights or to the collection of rentals or royalties on telephones. Expenses, incurred in whole or in part in respect to inventions or improvements which are or may be used otherwise than in telephones, shall be apportioned, and such part thereof as may be justly chargeable to the telephone interest shall be borne by the parties hereto in the proportion above stated, and such part thereof as shall justly be chargeable to other interests shall be borne by the owners thereof.

(2.) The party of the second part may, from time to time, acquire such inventions and improvements in telephones as it shall deem advisable, and may introduce such of them as it sees fit into the construction of telephones put out to its licensees, and to reimburse itself for the cost thereof, may charge an additional price to its customers beyond the price then previously charged, but such an increase shall not operate to increase the royalty or bonus payable to the party of the first part hereunder until said second party shall have been so reimbursed, unless said first party shall elect and assent to bear and pay twenty per cent. of such cost. Or if the party of the second part shall deem it advisable not to raise the price as aforesaid, then the party of the first part shall bear, pay and be charged with twenty per cent. of said cost actually and in good faith incurred and paid, and the party of the second part shall bear, pay and be charged with eighty per cent. thereof. *Provided*, that if such payments are for rights which extend beyond the duration of this contract, or which are to be applied to purposes other than telephonic, then only a *pro rata* proportion, according to time or the purpose for which they are used, shall be borne by said first party. *And provided further*, that if the purchase of any one patent calls for an absolute payment exceeding $10,000, no portion of the excess over that sum shall be charged to the party of the first part, unless it shall consent (and full opportunity shall be afforded it to do so) or it be determined by the board contemplated in Article 2, or by some other competent tribunal, that it should be so charged in respect of such excess; and said board shall so determine if, or so far as they shall find that said purchase was prudently made for the benefit of the parties hereto. Said second party shall call for said reference, and the referees shall be appointed, and such proceedings shall be had in reference thereto as are provided in said Article 2, so far as they can apply; and the questions submitted by the notice calling for said reference shall be determined by the default of the party or the decision of the referees, as therein provided; and the determination so arrived at shall be final and conclusive upon the questions so submitted.

ARTICLE 5. (1.) The party of the first part, for itself and those it represents, as aforesaid, hereby grants to the party of the second part, as far as they or either of them have the legal power so to do, an exclusive license during the full terms for which patents thereon have been or may be granted, to make, to use, and to license others to make and to use in speaking telephones, call bells, and switches, and other appliances for use on telephonic lines, any inventions or improvements therein which it, or those whom it represents, as aforesaid, now own or control, in whole or in part, by contract or otherwise, under which it or they have the authority to grant such license, and whether already patented or not, and which the party of the second part shall not otherwise have the right to use; reserving however to the party of the first part, and those it represents, the right to use said inventions in switches, call bells, and appliances other than telephones in connection with the telephones which they are or may become entitled to use under this contract. Instruments or apparatus made under this license shall be deemed to be licensed only for the uses above named, and not for any other purpose.

(2) And the first party further agrees to acquire any further inventions adapted to be used in connection with telephones which it may have the right to so acquire under existing contracts with George M. Phelps and Thomas A. Edison, and to license the second party under the same for use in telephones or on telephone lines, the second party agreeing to pay to said first party in reimbursements, whatever the said first party or those it represents may be required to pay therefor under the ninth, tenth, eleventh and thirteenth clauses of the agreement between Thomas A. Edison and the Western Union Telegraph Company, dated May 31, 1878, and whatever it may be required to pay said Edison under the contract between the same parties, dated May 12, 1879, and whatever it may be required to pay George M. Phelps in addition to his salary of $3,300 therein referred to, to acquire his inventions under the contract between him and the Western

Union Telegraph Company, dated January 20, 1876, or a due and proportionate part thereof, in case said inventions shall also be applicable to uses and purposes other than telephonic, said licenses to be exclusive during the term of this contract, and to continue but not to be exclusive thereafter; the character and extent of such license shall be taken into account in arriving at a fair proportion of the actual cost thereof.

(3.) And if the parties of the first part shall hereafter acquire ownership or control as aforesaid of other inventions adapted to be used in connection with telephones, the second party shall have the right or license to use the same for telephonic purposes, and shall be bound to pay to the party of the first part the cost thereof, or a due and proportionate part of said cost. Such right or license shall be exclusive for telephonic purposes during the whole period of this contract, and shall continue, but shall not be exclusive after its expiration; the character and extent of such license shall be taken into account in arriving at a fair proportion of the actual cost thereof.

(4.) Said second party will pay on instruments, which shall be made by or for it, the royalties specified in Schedule A, hereby referred to and made part of this agreement, so far as the first party or those it represents shall be bound to pay the same under the contracts therein referred to, unless it may have the right to make and use such instruments irrespective of this contract and of the contracts referred to in said Schedule by reason of the invalidity of the patents therein referred to, or otherwise, in which cases it shall not be deemed to be acting under any license from the party of the first part or those it represents; but it hereby agrees to indemnify the party of the first part and those it represents for any such royalties it or they may be legally bound to pay by reason of any use by the party of the second part.

(5.) This contract shall operate as a release to the parties hereto, and those they represent, and their respective licensees and predecessors, for all claims for infringement of patents on which suits are now pending, in which said parties, or any of their licensees or predecessors are parties, and all claims for infringement of other patents or inventions owned or controlled by them, or either of them, growing out of, or based upon, the manufacture or use of telephones now used in territory to which this contract applies at once; but, as to telephones in territory to which it does not apply at once, it is not to operate as such release (and each party stands on its own right in such conflicting territory) until settlements are made and interests harmonized as hereinafter provided, or until the parties hereto agree that it shall operate as a release upon telephones in such localities, and in either of such cases it shall thereupon operate as a release in respect of telephones in such locality.

ARTICLE 6. Except as herein provided, the first party and the companies it represents agree to withdraw from the manufacture, rental and use of telephones.

ARTICLE 7. The party of the first part agrees to give assistance and co-operation in developing and extending the use of the telephones of the party of the second part; and that the party of the second part shall, during the term of this contract, and when in the judgment of the first party it shall not interfere with the enjoyment and use of the same by said first party for telegraphic purposes, have permission to build lines under any franchises, contracts, licenses, or rights of way enjoyed or controlled by the party of the first part, or to use any poles, fixtures, structures, or plant of said first party, upon reasonable terms, subject, however, to a revocation of such license to use any poles, structures, fixtures or plant, at any time, by reasonable notice to the party of the second part.

ARTICLE 8. Whereas it is intended as a part of this agreement that all telephones heretofore put out under lease or under license by and from the party of the first part and those it represents shall, without any exception (except temporarily where this contract does not at once apply), become the property of and come under lease and license from the party of the second part, and, when so transferred and placed under lease and license in accordance with the terms hereof, shall not be pursued or treated as infringing instruments in respect of any use thereof prior to the date of this agreement:

And whereas it is also intended that all telephone exchanges which have heretofore been established by the party of the first part or those it represents, or by or under contracts with them or some of them shall, together with their plant, be transferred to the party of the second part and become its property, and that all interests of the party of the first part or those it represents, whether as holders of stock or other interests in telephone exchanges or corporations or organizations owning or maintaining exchanges shall be transferred to the party of the second part and become its property, except in the localities named in section (5) of this article:

And whereas the party of the second part or its predecessors, owners of the Bell patents, have heretofore granted certain licenses, and made certain contracts, exclusive in their character to a certain extent, which may render it impracticable or improper for it to so accept and license some of said telephones and exchanges without the consent of the grantees of such previous licenses who are not parties hereto, and whereas the party of the first part, or those it represents, may not be legally able to transfer some of said property or interests without the concurrence of third parties so that certain of the transfers desired cannot be made, or cannot be accepted and the intended licenses given until arrangements or modifications of contracts can be made with one or both the present licensees claiming conflicting rights (as may be necessary in each case), which will permit the transfers and licenses so intended and desired to be made and granted:

Now, therefore, it is agreed as follows:

(1.) In the places named in Schedule B, hereby referred to, and made part of this agreement, in which places it is understood that no such conflict exists, the exchanges and interests in exchanges owned by the party of the first part, or those it represents, and all the property connected with such exchanges, including contracts of the subscribers, and all telephones in said localities shall forthwith be transferred and delivered to and put under lease or license from the party of the second part and paid for by it as hereinafter provided, except that telephones which already belong to the party of the second part are not to be again paid for. All the interest owned by the Gold and Stock Telegraph Company in the American District Telegraph Company at Boston is to be included in the transfer provided for by this section.

(2.) In the *places* named *in Schedule C* hereby referred to and made part of this agreement, in which places it is understood that the *party of the first part* or those it represents are *sole owners of* all the *exchanges* established and all the telephones put out by or under it or them, but in which the party of the second part has granted licenses which may conflict as aforesaid, the *party of the first part*, and those it represents, *will transfer* all *such exchanges* and telephones *to the party of the second part, who will accept and pay for said exchanges*, and accept, pay for and license said telephones as herein provided, but the party of the second part shall not be required to take, pay for, and license the same as aforesaid, until opportunity has been afforded for the requisite arrangements to be made as aforesaid with its licensees, or it shall elect to accept, pay for, and license the same without waiting for such arrangements to be made.

(3.) This contract shall not operate upon nor affect the telephones and exchanges in the places specified in Schedule D until arrangements have been made with owners or part owners of exchanges therein who are not parties hereto, or until the parties hereto shall agree that it shall operate therein. But the provisions of sections (8) and (9) of this article shall apply to such localities. Upon the transfer of said interests the parties hereto, and those represented by them, will use their best endeavors to to cause all telephones in said localities, which have been manufactured or furnished by or on behalf of the first party, or those it represents to be transferred to and put under license from the party of the second part as aforesaid, and the same shall thereupon be accepted, paid for, and licensed by said party of the second part as herein provided.

(4.) With regard to the price to be paid by the party of the second part to the party of the first part for instruments and all properties and interests to be transferred hereunder, it is agreed as follows: for the instruments specified in Schedule E, hereby referred to and made part hereof, there shall be paid the amounts therein specified respectively, or a proportional part thereof upon the delivery of a portion of said instruments less than the whole number specified, payment to be made upon delivery of the same as herein provided; and in renting such of said instruments as include a transmitter, call bell and switch, being the twenty-two kinds first named in said schedule, the party of the second part may charge a rent or price for the call bell and switch in addition to the standard rent of the telephone itself, and an amount of such additional rental not to exceed three dollars per annum for a period which shall yield an amount equal to nine dollars on each instrument shall be rated as applying to the call bell and switch in said instruments, and on this amount no royalty or bonus shall be paid to the party of the first part. In addition to the sums specified in said schedule the party of the second part will pay the royalties of twenty or twenty-five cents a switch which have been paid on switches included in said schedule and made under contracts with T. B. Doolittle or H. L. Roosevelt. All exchanges which the party of the first part or those it represents have established and own, and all interests, entire or partial, which are to be transferred hereunder, acquired by them in other exchanges or in corporations owning exchanges, are to be paid for when transferred at the actual cost to the party of the first part or those it represents, at the time of transfer, of establishing or purchasing the same, not taking into account any profits or losses in operating the same nor legal expenses in patent suits. Exchanges and exchange plant (which are to be paid for at actual cost), include wires, lines, poles, fixtures and other appliances, and also all call bells, batteries, switches and switch-boards which are in use or on hand fit for use, and are owned and paid for by the exchange, but where the telephone lines have been placed upon poles or fixtures erected for telegraph lines such poles and fixtures are not to be transferred, but the party of the second part may continue to use the same under and subject to the provisions of Article 7. In cases where the value, cost or price remains to be fixed or ascertained, if the same cannot be agreed

upon by the parties hereto, it shall be appraised, fixed or determined by two disinterested experts, one to be chosen by each party; and if the two so chosen cannot agree they shall choose a third, and the decision of the majority shall be binding upon the parties.

(5.) The undertaking of the party of the first part, and those it represents, to transfer all their interests in telephonic district or exchange systems, and corporations or organizations owning them, shall not be held to include the stock interests of said first party and those it represents in the "Philadelphia Local Telegraph Company," "The Central District & Printing Telegraph Company" of Pittsburgh, the "Gold & Stock Telegraph Company of California," the "Michigan District Telegraph Company" of Michigan, which companies have some interests in telephonic exchanges; nor to include their interests in the properties (other than telephones) in the exchanges within thirty-three miles of New York City Hall. The party of the first part and those it represents will, as soon as local conflicting interests can be harmonized, transfer to and put under lease and license from the party of the second part, upon its acceptance and payment for the same as herein provided, all telephones in said New York territory, and in the localities covered by the companies above mentioned, and will use their best endeavors to procure this to be done as soon as possible.

(6.) As to all telephones heretofore put out by the party of the first part or those it represents, for uses for which it or they are entitled to be furnished with telephones as provided in Article 14, they shall transfer the title in the same to the party of the second part, and thereupon shall receive leases and licenses for the same in accordance with this contract, and the party of the second part shall pay for such telephones as herein provided. In all cases where the party of the first part or those it represents are to be licensees of telephones now out and the title in which under the provisions hereof is to be transferred forthwith, they shall begin to pay the rental and royalty thereon and licenses shall issue as from the day this agreement takes effect, and at the present recognized standard rate until some other shall be established in accordance with the provisions hereof. But any such telephone which cannot be so transferred, accepted and and licensed, by reason of conflicting or inconsistent rights heretofore granted by the owners of the Bell patents to their licensees, shall not be paid for nor shall the rent or royalty thereon begin until such conflicting interests can be harmonized as herein provided so as to permit such transfer, unless said second party shall elect sooner to take, pay for and license the same; and until such transfer the provisions of this contract shall not apply to any telephone so situated, and the party of the first part and those it represents shall, in the meantime, stand as they would have done with reference thereto had this contract not been made.

(7.) All telephones, as to the transfers of which special provision has not been hereby made, are to be transferred to and paid for by the party of the second part, and by it licensed directly to customers and users forthwith in the manner and with the effect herein provided, or as soon as practicable as aforesaid.

(8.) With respect to the telephones, and the telephone exchanges and properties and interests the transfers of which may be delayed by reason of conflicting claims or interests as hereinbefore provided, it is agreed that both parties will use their best endeavors and due diligence to arrange with their respective licensees and associates such modifications of existing obligations as will allow said transfer to be made at the earliest possible date. Until such time the parties of the first part will not transfer any of said properties (except so far as existing contracts may legally require them) to any person or party, unless approved by the party of the second part.

(9.) And the party of the first part, for itself and those it represents, agrees that previous thereto any of said exchange properties shall be transferred at said cost price, on request, to any party approved by the party of the second part, who shall not be a competitor in the telegraph business with the Western Union Telegraph Company, suitable provision first being made to protect from oppression the rights and interests of local and associate owners of the exchanges and exchange plant.

(10.) And said first party also agrees that suitable accounts, statements and information shall be seasonably furnished to the party of the second part, for the purpose of, or to assist in ascertaining the price to be paid for all properties and instruments which the party of the second part is to or may take and pay for under this contract.

(11.) Telephones which have been sold by the party of the first part, or those it represents, to institutions of learning and to the Government of the United States, shall be deemed to be licensed by the party of the second part, and shall not be made the basis of any claim for infringement.

ARTICLE 9. As to each locality named in Schedules C and D in which the transfer of the exchanges and telephones may be delayed, as provided in sections (2) and (3) of Article 8, and as to each locality mentioned in section (5) of said article in which the transfer of telephones may be delayed as provided in said article, and as to all telephones (not used on exchanges) in localities where the acceptance of telephones is delayed, as provided in (6) and (7) of said article it is agreed, so far as the conflicting class may extend, that, until the time shall arrive for the transfer for such locality to be made as in said sections is provided, the parties hereto respectively, and the owners or users of telephones or telephonic appliances, claiming or holding under persons whose claims create the conflict and give rise to the delay shall not have the benefit of any immunity or protection from suits by reason of this agreement or anything done hereunder or in consequence hereof, unless and until the parties hereto shall otherwise determine by a writing hereafter to be made; and nothing herein contained shall operate directly or indirectly, expressly or impliedly, as a license to any such person or party to use telephones or telephonic appliances within such locality, nor shall it in any way interfere with or affect the obligations which the parties to this agreement may be under respectively to their said licensees, or with any rights of the first party to supply telephones in such conflicting territories as provided in Article 11. No royalty or bonus shall be paid in respect of telephones used within such localities and not entitled to the protection hereof, unless actually accepted and licensed as provided in Article 10.

ARTICLE 10. (1) All telephones and apparatus which are to be taken, paid for and licensed by the second party hereunder shall be placed under written leases and licenses from it, in such form and at such rentals as said second party shall establish under the provisions of this contract, not different from those at the same time established for other telephones used for like purposes; and the transfer shall not be deemed to be complete nor shall the second party be required to accept, pay for, or license any instrument until it shall be pointed out, ear-marked, and such delivery made of it as the nature of the case will permit. No telephone shall be deemed to be accepted and licensed under the patents of the party of the second part, nor shall any person be entitled to any immunity whatsoever from claims for infringement of any patent by reason of the manufacture or use of such telephone, nor shall it be required to be paid for by the party of the second part until it shall be so delivered and put under written lease or license hereafter to be made, or delivered into the actual possession of the party of the second part, or shall be designated, ear-marked and offered to be put under such lease and license by the parties entitled so to do, including the party in actual possession and the party undertaking and bound to pay rental and royalty therefor. When any telephone shall be so accepted, leased and licensed, or shall be so offered within three months from the date hereof, and, under the provisions of this contract, be required to be accepted and paid for, its manufacture and use, prior to such time, shall not be made the basis of any claim for infringement of any patent.

(2) But the second party may, at any time it sees fit, after the expiration of six months from the date hereof, take from the party of the first part or those it represents any existing telephone (except those which the party of the first part or those it represents are entitled to have and use under the provisions of Article 14, and those which under Article 9 are temporarily excepted from the effect of this contract), with the existing license or contract for license for the same with all the rights of the owner or licensor, by a written notice to that effect given to the party in actual possession of the telephone, and also to the party of the first part, and thereupon it shall be entitled to receive the rental and royalty therefor, and be bound to take and pay for the same as herein provided; in such cases the bonus or royalty to be paid to the party of the first part under Article 1, during the continuance of such existing lease and license, shall be 20 per cent. of the rental actually received under the terms thereof; and in respect of all rights and interests transferred as provided in this article, said second party may, so far as necessary, but at its own expense, use the name of the first party or those it represents, to maintain and enforce all the rights and interest legally or equitably coming to it upon or by such transfer.

(3.) The rental of the telephones transferred or required to be transferred to the party of the second part hereunder shall, from the time such transfers shall be or ought to be made, accrue to and be collected by said second party, subject to the payment and allowance of the royalty, bonus, and commissions hereinbefore provided; when all such transfers have been made, and the conflicting interests of the respective licensees shall have been so far harmonized as to enable said first party to cease to manufacture and supply telephones as provided in Article 11 then said second party will receive and pay for all the remaining property belonging to said Gold and Stock Telegraph Company and American Speaking Telephone Company, of the character specified in Schedule E, at the prices therein stated. All telephones made for use after November 1, 1879, are to be paid for at actual cost when transferred.

ARTICLE 11. (1.) The first party reserves all such rights as it now possesses to continue to manufacture and supply its own telephones, notwithstanding the stipulations of this contract, to its own exchanges already established and in actual operation and subscribers thereto, and to its licensees, until the local conflicting interests between the respective licensees of the two parties hereto can be harmonized and until any property of said first party at such places shall be turned over to said second party and paid for, as hereinbefore provided; but said first party shall organize

no new exchanges, nor grant any new or additional licenses (except to additional subscribers to exchanges already established) creating new or additional conflicts or complications except within the radius of thirty-three miles from New York City Hall, and within the territory covered by the Ormes contract hereinafter referred to; and such places where such conflicting interests of licensees exist shall, until they can be so harmonized, be exempt from the operation of this contract as aforesaid.

(2.) But it is distinctly understood as an essential feature of this contract that all the telephone district or exchange systems except those within the radius of thirty-three miles from New York City Hall, and within the territory covered by said Ormes contract, are to be transferred to and accepted by the party of the second part at the earliest possible day, and that their continuance in the hands of the party of the first part during the meantime, is merely to give an opportunity for local interests to become harmonized and to avoid inconvenience to the public, and not as a source of revenue or advantage to the party of the first part or those it represents.

ARTICLE 12. (1.) The right to all uses of the telephone on wires of a district or exchange system is to remain exclusively with the party of the second part, excepting such temporary suspension of the application of this contract to certain localities, as has been already herein provided for.

(2) For the purpose of this contract it is agreed that an "exchange," or "a district or exchange system" applies to a system in which different stations on the same or different circuits, and either within any city or town or within a radius of fifteen miles of a central office (or within wider limits, where existing contracts have granted wider limits), are connected with such central office or branch offices within said territory for the purpose of placing subscribers or other parties by such circuits in communication with such central or branch offices or with each other, either directly or through the agents of the system.

ARTICLE 13. (1.) The right to connect telephonic district or exchange systems for the purpose of personal conversation between persons at the instruments, and the right to use telephones on all lines not forming a part of a telephonic district or exchange system for such personal conversation (except so far as licenses for private lines are to be granted to the party of the first part under Article 14) are to remain exclusively with the party of the second part, and those licensed by it for the purpose. But such connecting and other lines are not to be used for the transmission of general business messages, market quotations, or news for sale or publication in competition with the business of the Western Union Telegraph Company, or with that of the Gold and Stock Telegraph Company. And the party of the second part, so far as it lawfully and properly can prevent it, will not permit the transmission of such general business messages, market quotations or news for sale or publication over lines owned by it, or by corporations in which it owns a controlling interest, nor license the use of its telephones or patents for the transmission of such general business messages, market quotations or news for sale or publication in competition with such telegraph business of the Western Union Telegraph Company or that of the Gold and Stock Telegraph Company.

(2) The terms "general business messages" and "telegraph messages," or "messages for hire," are defined to mean all communications in behalf of other parties than those who directly communicate by the telephone by themselves or their servants or agents personally present at the instruments; and no person engaged in the business of transmitting messages for other parties shall be authorized or knowingly allowed by the party of the second part, or its servants or agents, to transmit such messages through the telephone.

(3.) It is, however, understood, that the stipulations of this contract relating to the transmission of telegraph messages shall not operate to restrain the renting of telephones by the party of the second part to railroad companies for strictly railroad messages, or for general business messages in connection with the Western Union Telegraph Company or its auxiliary corporations or organizations, nor so as to restrain, impair or affect the right of the party of the second part to use telephones by themselves or their licensees for all purposes in territory not occupied or covered by the Western Union Telegraph Company or its auxiliary corporations or organizations, nor from contracting with the Northwestern Telegraph Company and other companies as to territory not occupied or covered by the Western Union Telegraph Company or its auxiliary corporations or organizations at the time such contracts or licenses are made, or with the Government for lines in the Territories, or for Government lines for Government messages in the States. For the purposes of this contract the Western Union Telegraph Company is deemed to occupy and cover all the thirty eight States of the United States, the District of Columbia and the Territories of Washington and Utah, except the Territory of the Montreal Telegraph Company, to wit, that part of the State of New York which is west of Lake Champlain and north of a line drawn from Whitehall to Oswego, and except the territory of the Northwestern Telegraph Company, to wit, the State of Wisconsin (except the line between Chicago and Milwaukee), the State of Minnesota, that part of Iowa which is North of Sioux City, and the upper peninsula of Michigan, and except all that part of Florida which is not reached by the lines of the International Ocean Telegraph Company or of the Western Union Telegraph Company.

(4) The party of the second part will not knowingly grant any license to use telephones for any purpose for which it agrees not to use them as specified in this article, and it will insert in all its licenses, such apt and suitable restrictions as under the advice of counsel are deemed reasonable and proper to that end and upon notices of any breach thereof will use all reasonable means to enforce the performance and observance of the same. But it is understood that the party of the second part is not to be held responsible for any breach of the stipulations of this article and article 15 of this contract not committed by its officers or servants unless it had reasonable notice and failed to use reasonable means to prevent it.

(5.) The whole expenses of litigation, if any shall arise with third parties in consequence of the stipulations of this article relating to the transmission of general business messages, market quotations or news for sale or publication, or acts in pursuance thereof, or attempts to enforce the same, shall be borne by said Western Union Telegraph Company. Said last-named company shall also have the control of all such of said suits as do not bring in question the validity, construction, or effect of, or title to, the patent rights of the party of the second part, or any of them, whether held by ownership or license, and for that purpose it shall be the duty of said second party to give due authority to such counsel and such attorneys in law or in fact, as the Western Union Telegraph Company may nominate to institute, appear in and conduct such suits, in the name of the second party if necessary.

ARTICLE 14. (1.) The party of the second part will fully license the party of the first part to use telephones procured from it for transmitting telegraph messages, and for use on private lines, with the right to sublet the use thereof along with such private lines, for such purposes as such private lines have been and are being used, except in territories where exclusive agency contracts inconsistent with this agreement to license already exist, and during the continuance of such agencies, in which cases they may obtain them from such agents.

(2.) For the purposes and uses aforesaid, the party of the first part shall be furnished with telephones, with licenses from the party of the second part to use such telephones and other inventions owned or controlled by it for use in connection with telephone lines, on terms which may be established from time to time, and which shall be as favorable as those on which they are furnished to any other parties for like uses, and shall be allowed a discount as provided in Article 2.

(3.) The party of the second part shall have the right from time to time to incorporate in its leases and licenses such apt and suitable stipulations as it may deem requisite for the control, preservation, and protection of its telephones in the hands of licensees, to secure the payment of royalties and rentals, to protect itself against the application and use of telephones for uses different from those for which they are rented or licensed, and to aid it in protecting the patents owned by it or under which it has licenses, and its title thereto, from infringement or attack, and it may prescribe and require the party of the first part to incorporate such stipulations into all licenses, leases and sub-leases of telephones, granted by it; but no stipulations shall be incorporated in the licenses and leases to the party of the first part or prescribed as aforesaid, for the licenses and leases to be granted by it, different from those in use for other licenses for like purposes.

(4) For the purposes of this contract "private lines" are understood to refer to telephone lines, each consisting of a single circuit on which telephones are to be used for the individual and private business of the individuals, business firms, or corporations leasing the same. Such telephones are not to be used by any other parties than those leasing them, except on business of the parties so leasing, nor is any business to be transacted by or through them for a consideration or toll to be paid by other persons than those so leasing them. Such private lines or circuits shall not extend more than twenty-five miles beyond the municipal limits of the city or town in which one end of the line is situated, nor shall any one line or circuit be used for more than two individuals, firms, or corporations at each end, nor shall any two or more lines or circuits be connected.

ARTICLE 15. (1.) The second party will turn over and deliver to the Western Union Telegraph Company of the first part, or its agents, exclusively, all messages for transmission to other points by telegraph, collected by or coming on the wires or within the control of its telephonic exchanges or district systems or those of its licensees, wherever the first party has wires and is prepared to receive or transmit the same, so far as said second party can lawfully control the same, and unless otherwise specially directed by its customer; but will not solicit such special direction nor receive and pay tolls for transmission over other lines, unless compellable by law so to do. And the first party shall forward the same to destination, subject to its established rules and regulations, upon payment of regular tolls, and pay to said second party a commission of fifteen per cent. on all the tolls received for transmitting such messages over its lines; the commission not to include tolls for the transmission over other lines, nor tolls for transmitting

cable messages. For delivery service of telegraphic messages made through said second party or its licensees, and for collecting through a messenger service for delivery to said Telegraph Company, the party of the first part will pay a fair compensation, the same that is paid to district telegraph companies for similar services.

(2.) If the second party, for the purpose of doing a general telegraph or telephone business, shall connect a telegraph station of the Western Union Telegraph Company by a branch line, with any place in territory occupied or covered by the Western Union Telegraph Company which has no Western Union line or office, it shall turn over and deliver to the Western Union Telegraph Company, exclusively, so far as it has legal power to control the same (unless it be specially directed by the customer sending the same that they be forwarded by some other route,) all messages collected from such points so connected. And said Western Union Telegraph Company will, as hereinafter provided, receive, and forward the same upon payment of regular tolls, and pay to the second party or its agents a commission of ten per cent. upon the tolls received for transmitting such messages over the Western Union Telegraph lines (cable messages excepted from such commission); and there shall be added to the rate of tolls to be collected from customers a further rate not exceeding ten cents per message of ten words on such branch lines of the length of ten miles or less, and five cents additional per message of ten words for each additional ten miles or fraction thereof in length of said branch lines, and at the same rate for longer messages; such tolls so added shall belong to the party of the second part.

(3.) When the second party shall have constructed such branch lines to such new points within the territory occupied or covered by the Western Union Telegraph Company, but not theretofore reached by its telegraph lines, and the telegraph company of the first part shall thereafter elect to construct its lines of telegraph to such new points, it shall, if required by said second party, take and pay for the lines of the second party at cost, and also pay said second party the commission provided in section (2) of this article on all the business taken at such point for the period of twelve months thereafter. But if the party of the second part shall elect to keep its own lines, the provisions contained in Article 13, against the transmission of general business and other messages, shall apply to such line.

(4.) Where any messages are to be delivered between the parties through the telephone, said party of the first part is to afford to the party of the second part, at the expense of the second party, the facilities for providing a telephone connection between its office and the office of the district exchange or branch line, and shall at its own office, without further cost to the party of the second part or its licensees, receive or transmit said messages over said connecting line by its own clerks, who for that purpose shall be the agents of the second party and subject to its rules and regulations.

(5.) It is also agreed by the party of the first part, for itself and those it represents, that it will not connect its telegraph lines with any telephonic district or exchange system other than those licensed by the party of the second part, so far as it lawfully can refrain from so doing, except in districts and during the time temporarily excepted from the operation of this contract.

(6.) All messages or communications of customers delivered by either of the parties to the other for further transmission over its telegraph or telephone lines, as the case may be, shall be deemed to have been delivered and received subject to such established rules, regulations and conditions of the receiving company as may have been established and promulgated by it for the government of its business and not otherwise; and for the purpose of regulating and limiting the responsibility of the party receiving from the other a message or communication in this manner, it shall be the duty of the company receiving the message directly from the customer to require his assent to such rules, regulations and conditions of the other company by writing his message or communication upon the regular contract blanks of such company, or blanks containing an equivalent contract, or in such other manner as may be generally required by such company for that purpose from its direct customers; and if either company, dealing with the customer in the first instance shall fail in the duty last above stipulated, it shall hold the other company harmless from all claims for damage which it may be compelled to pay to the customer because of the absence of a contract arrangement with such customer subjecting the business in question to such established rules, regulations and conditions of the company thus rendered liable to the customer; the object of this stipulation being to limit the responsibility of each party to matters happening upon its own lines, and to secure the regulation of that responsibility in respect to all business originating beyond its own lines, in the same manner as such responsibility shall be regulated in respect to business beginning, continuing and terminating upon its own lines. Whenever any such rules, regulations or conditions shall be established or modified by either party the same shall be notified to the other party.

Article 16. The existing suits and interferences shall be disposed of as counsel of the parties of the first and second part may advise, to recognize and protect the rights of the several inventors to their respective inventions, subject to the orders of the courts and the decisions of the Patent Office.

Article 17. This contract shall go into effect as of the first day of November, 1879, and shall be and remain in force until the expiration of seventeen years thereafter. It shall cover the whole territory of the United States, except that included in the Ormes contract (which territory shall be included in this contract upon the expiration of said Ormes contract), and those conflicting localities hereinbefore referred to and temporarily excepted, and shall cover them as soon as those exceptions expire. Said Ormes contract is a contract dated August 26, 1879, to which James M. Ormes, the Western Union Telegraph Company acting for the same parties as in this contract, and the National Bell Telephone Company are parties; the territory covered by it is as follows: West Virginia south of the Baltimore and Ohio Railroad, Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama. For the further contents of said contract, so far as is material, reference thereto is hereby made.

Article 18. (1.) The party of the second part shall keep in regular books for that purpose, accounts of the number of telephones manufactured, licensed, and put out for use in the United States, and also of the rentals received and commissions or allowances paid or allowed as herein provided and of the number manufactured and sold in foreign countries and the amount received therefor. And said accounts shall, at regular quarterly intervals and at all reasonable times be open to inspection by the party of the first part, for the purpose of ascertaining the royalties or bonus due hereunder, and of verifying the accounts rendered, and copies of said accounts shall be rendered at the time of the quarterly accounting. Tolls collected by the one party for the other, and commissions on telegraph business, shall be paid monthly at the place where business is exchanged. All accounts for royalties, and all other unsettled accounts shall be settled, and the balance paid on the first day of February, May, August and November, up to the first day of the preceding month. All such accounts shall be verified by oath of the person having the best knowledge of the facts. Payments of the balances resulting from such accounts shall be made to the treasurer of the Gold and Stock Telegraph Company as representative of the party of the first part, or the treasurer of the second party, as the case may be, or such other persons in Boston or New York as the respective parties may from time to time appoint. Such persons shall have authority to settle all said accounts, and to receipt for the money.

(2.) The party of the first part or its said representative is to be promptly notified of all reduction of rentals.

Article 19. It is understood and agreed that nothing herein contained shall be construed as imposing upon either party any obligation to do or not to do at any time anything contrary to law; and if anything herein covenanted or contemplated to be done or not to be done shall be or become contrary to the law of the land, the consequent inability and failure to perform the same shall not operate as a dissolution of this contract, nor to give to either party a right of action against the other.

Article 20. All the provisions and stipulations herein contained and described as incumbent on or for the benefit of the parties hereto, shall be incumbent on or for the benefit of their respective successors or assigns.

In witness whereof said Western Union Telegraph Company hath caused these presents to be subscribed by its President, and its corporate seal to be hereto affixed by its Secretary, and said National Bell Telephone Company hath caused its corporate seal to be hereto affixed by its Clerk and these presents to be subscribed by its President and Treasurer on the day first above written.

THE WESTERN UNION TELEGRAPH COMPANY,

By Norvin Green, *Prest.*

{ Seal Western Union Tel. Co. } Attest,

A. R. Brewer, *Sec'y.*

THE NATIONAL BELL TELEPHONE COMPANY,

By W. H. Forbes, *Prest.*

Geo. L. Bradley, *Treas.*

{ Seal National Bell Telephone Co. } Attest,

Chas. Eustis Hubbard, *Clerk.*

The above-named Gold and Stock Telegraph Company, American Speaking Telephone Company, and Harmonic Telegraph Company, hereby acknowledge the authority of the Western Union Telegraph Company to represent and act for them in the matters embraced in the foregoing contract, and agree to be bound by and to carry out its provisions, it being understood and agreed by and between said named parties that the royalty and bonus upon telephones, herein provided to be paid to the said Western Union Telegraph Company, shall be paid to the said

Gold and Stock Telegraph Company for the use and benefit of said American Speaking Telephone Company.

IN WITNESS WHEREOF said parties have severally caused these presents to be subscribed by their respective Presidents, and their corporate seals to be hereto affixed by their respective Secretaries on the day of the date of said contract.

THE GOLD AND STOCK TELEGRAPH COMPANY,
By GEORGE B. PRESCOTT, *Vice-Prest.*

{ Seal Gold & Stock Tel. Co. } Attest,
J. D. REID,
Sec'y.

THE HARMONIC TELEGRAPH COMPANY,
By E. W. ANDREWS, *Prest.*

{ Seal Harmonic Telegraph Co. } Attest,
H. H. DUNCKLEE,
Sec'y.

THE AMERICAN SPEAKING TELEPHONE COMPANY,
By NORVIN GREEN, *Vice-Prest.*

{ Seal Ameri'n Speaking Telephone Co. } Attest,
J. D. REID,
Sec'y.

SCHEDULE A.—The royalties which are referred to in (4) of Article 5 are:

A royalty of twenty cents per switch under a contract between the Western Union Telegraph Company and Thomas B. Doolittle, dated June 14, 1879, relating to said Doolittle's patent, No. 209,-115, granted October 22, 1878. The Western Union and Gold and Stock Telegraph Companies have, under said contract with Mr. Doolittle, made and paid him royalty on upwards of 5,000 of these switches.

A royalty of twenty-five cents upon each telephone embodying any of the inventions or improvements covered by the patent No. 218,582, granted to Sidney H. Short, August 12, 1879, under contract between the Gold and Stock Telegraph Company and said Short, dated August 22, 1879.

A royalty of twenty-five cents on each automatic switch which shall be made or used by the party of the second part, under H. L. Roosevelt's patent, No. 215,837, of May 27, 1879, by virtue of the license contained in Mr. Roosevelt's letter to Mr. George B. B. Prescott, dated June 21, 1879.

The party of the second part does not hereby admit the validity, effect, or value of any of said patents.

SCHEDULE B.—Places where the Western Union Telegraph Company or the Gold and Stock Telegraph Company have established exchanges or leased telephones, and the owners of the Bell patents have granted no exclusive rights to other parties, or where the Western Union Telegraph Company or Gold and Stock Telegraph Company have bought the Bell licenses, or interests therein.

No hostile interests are here to be reconciled, and the transfers may take place at once.

1. Places where exchanges were established and are owned by the Western Union Telegraph Company, and on which the telephones of the American Speaking Telephone Company are used: Atchison, Kan.; Akron, N. Y.; Auburn, N. Y.; Boston, Mass.; Chester, Pa.; Concord, N. H.; Danville, Ill.; Decatur, Ill.; Davenport, Iowa; Defiance, Ohio; Evansville, Ind.; Galveston, Texas; New London, Conn.; Houston, Texas; Kansas City, Independence, Mo.; Lafayette, Ind.; Leavenworth, Kan.; Little Rock, Ark.; Moline, Ill.; Meriden, Conn.; Pekin, Ill.; Pittsfield, Mass.; Portland, Me.; Providence, R. I.; Pawtucket, R. I.; Rock Island, Ill.; Richmond, Ind.; Rutland, Vt.; S. Norwalk, Conn.; Springfield, Ill.; Stamford, Conn.; St. Louis, Mo.; Topeka, Kan.; Washington, D. C.

Places where the Western Union Telegraph Company has acquired a part or the whole of the interest of the Bell licensees: Bridgepert, Conn., the whole; Columbus, Ohio, the whole; St. Louis, Mo., majority interest; Providence, R. I., Pawtuckt, R. I., majority interest.

The Gold and Stock Telegraph Company own the telephone exchange in Boston. The stock owned by the Gold and Stock Telegraph Company in the American District Telegraph Company of Boston, is to be transferred with the Boston Exchange.

SCHEDULE C.—Places where the Western Union Telegraph Company, or the Gold and Stock Telegraph Company have established and own exchanges, or have leased telephones, and where the owners of the Bell patents have granted rights to other parties under which those other parties might object to the use of the telephones put out by the Western Union Telegraph Company, or the Gold and Stock Telegraph Company. In these cases, the Western Union Telegraph Company, or the Gold and Stock Telegraph Company could transfer at once, but the interests or obligations of the National Bell Telephone Company require that it shall have an opportunity to arrange with those licensees. Bloomington, Ill.; Dayton, Ohio; Fort Wayne; Syracuse, N. Y.; Fayetteville, N. Y.; Fall River, Mass.; Hartford, Conn.; Indianapolis, Ind.; Keokuk, Iowa; Lockport, N. Y.; Manchester, N. H.; New Haven, Conn., Niagara Falls, N. Y.; Norwich, Conn.; Peoria, Ill.; Rochester, N. Y.; St. Joseph, Mo.; Tonawanda, N. Y.; Trenton, N. J.; Cincinnati, Ohio.

SCHEDULE D.—Places where exchanges have been established, and have used telephones furnished by the Gold and Stock Telegraph Company. (1) Exchanges in which the Western Union Telegraph Company owns a stock interest: Albany and Troy territory, N. Y.; Newburg, N. Y.; Worcester, Mass.; Springfield and Holyoke, Mass.; Cleveland, Ohio; Erie, Pa. (American District Co.); Louisville, Ky. (contract made but no instruments furnished); Denver, Col.; Central City, Col.; Black Hawk, Col.; Golden, Col.; Georgetown, Col.; Leadville.

(2) Exchanges established and using telephones furnished by the Gold and Stock Telegraph Company, but in which neither the Western Union Telegraph Company nor the Gold and Stock Telegraph Company have any interest. Buffalo and Williamsville, N. Y.; Chicago, Ill.; Dubuque, Iowa; Des Moines, Iowa; Milwaukee, Wis.; Toledo, Ohio; Lawrence, Mass.; Quincy, Ill.; Utica and suburbs, N. Y.; Poughkeepsie, N. Y.; Camden, N. J.; Wilmington, Del. *Memo.* The owners of the Bell patents have granted licenses, or made agency contracts for the Albany and Troy district, Worcester, Springfield and Holyoke, Cleveland, the six towns in Colorado, Buffalo and Williamsville, Detroit, Milwaukee.

SCHEDULE E (not printed here) comprises a list of Phelps, Edison, Bergmann, Gray and other styles of receivers and transmitters, etc., several thousand pieces of apparatus being thus transferred at various prices approximating cost of manufacture.

The agreement as above accepted, signed and sealed bears date of Sept. 27, 1879, was approved by the National Bell stockholders on October 24, 1879, and the directors on November 12. It was approved by the Executive Committee of the Western Union Telegraph Co. on November 12, 1879; the directors of the Gold & Stock Telegraph Co. on November 10, 1879; the directors of the American Speaking Telephone Co. on October 30, 1879; and the directors of the Harmonic Telegraph Co. on October 28, 1879.

GENERAL TELEPHONE PROTECTIVE ASSOCIATION.

A meeting of the above Association—the same as has been referred to in previous issues as the Eastern Telephone Protective Association—was held in New York on August 20th, when the organization was completed. The object of this association is to protect its members and their customers from any and all suits that may be brought against them for infringement of the Berliner patent No. 463,569; and the further object of this association will be to reduce the cost of telephone service to the public. The association is now composed of sixteen members. Mr. A. F. Stanley, of Stanley & Patterson of New York is secretary, and also a member of the executive board composed of four members. All the members who have joined so far represent manufacturing companies East of Pittsburgh. The association will immediately employ counsel to go to Boston, to watch the case of the American Bell Co. vs. the National Telephone Mfg. Co., and to assist in whatever way possible in the defence of the Century Telephone Co. and the Bay State Telephone Co., who have also been sued by the American Bell Co.

MUNICIPAL TELEPHONE CRAZE IN OHIO.

A special dispatch of Aug. 18 from Cincinnati says:—Following the craze for water works and electric lights, the smaller cities of Ohio and Indiana are now putting in telephone exchanges. It is a new system, and the city puts in and owns the plant. Chillicothe, Ohio, a town of 16,000 population, has, within a fortnight, completed its plant, and it is working splendidly. The Bell Company left the field. The new company rents the telephones to private residences for $18 a year, while business houses pay $24. The following is the estimated cost of operating the plant, 200 telephones being in operation: Construction of telephones, $10,000; income, 150 telephones, at $18 per annum, $2,700; 50 at $24, $1,200.

FORTY MILES OF SHEEP RANCH TELEPHONY.

The Clark Brothers, whose sheep ranches extend from the Teton river to Birch creek, Mont., a distance of 40 miles, contemplate putting in a telephone extension from a point six miles west of Dupuyer through the latter place on to Pondera, connecting with Fairfield & McCuaige's two ranches, the three ranches of C. R. Scoffin and the two ranches of John Joiner. At Pondera connection will be made with Great Falls. The extension for which the money has already been subscribed will be about

36 miles, which, added to the lines now in use by the Clark Brothers, will make 100 miles of wire. Their principal ranch is on the Muddy and every one of their other ranches is in connection with the home place by telephone. Thus in the severe season all the herders are called up at 4 o'clock in the morning and asked for reports as to the weather, direction of wind, cloudiness and other meteorological data, and when these reports are all digested directions are given for the day's work to the herders. The system is one that has worked with marvelous satisfaction, and many times large bands of sheep have been saved from disastrous consequences by sudden and severe changes in the weather during the winter months.

LONG DISTANCE TELEPHONY IN ST. LOUIS.

Manager Durant, of the Bell Telephone Company, says that St. Louis will be connected by long distance telephone with all the big cities by next spring.

The Bell Telephone Company has received three car loads of copper wire for metallic circuits in St. Louis. The Bell Company has been endeavoring for five years to get authority from the Municipal Assembly to lay conduits. Failing in this, the company has decided to wait no longer, but to string the wires overhead. In order to do this the whole telephone system of St. Louis will have to be reconstructed, and two copper wires, instead of one, strung to each subscriber, thus making a metallic circuit.

The estimated cost of the change is $200,000, $100,000 of which is the cost of changing the central exchanges. There will be four central exchanges instead of two. After the metallic circuit is completed in St. Louis, it will take 60 days to make the long distance connection, the nearest connection being Terre Haute.

GERMAN TESTS OF THE TELEPHONE IN WAR.

An interesting experiment of installing a telephone by trotting cavalry was recently successfully undertaken by some Prussian Uhlans between Berlin and Potsdam. Two sets of one officer and two non-commissioned officers proceeded in the early morning respectively from Berlin to Potsdam. Each set was equipped with a complete telephone apparatus which one of the men carried in a leather case on his chest, besides the requisite quantity of thin wire. The end of the wire was connected with the respective towns' telephone station, and the wire was, by means of a fork fixed at the end of the lance, thrown over the tops of the trees along the road. As each kilometre of wire was thus suspended a halt was made, and it was ascertained whether there was connection with the station. A new kilometre of wire was then connected with the former, and on went the men. The two sets met at Teltow. The wires, having been respectively tested with their respective stations, were connected, and telephonic connection between Berlin and Potsdam was established. The distance is about twenty miles, and the whole thing was done in about four hours.

TELEPHONE NOTES.

SIDNEY, N. Y., is to have a telephone service.

CLARKSVILLE, TENN.—The Clarksville Telephone Exchange is ready to begin business.

GALESVILLE, WIS.—The Galesville-Winona telephone line is to be extended to Ettrick and North Bend.

OXFORD, PA.—The Octoravo Telephone and Telegraph Company has been formed; capital, $50,000.

CHICAGO, ILL.—The Western Union Telephone Company has been formed; capital stock, $100,000. Incorporators—Arthur Dixon, Wilfred Massey and Samuel B. Foster.

LEWISBURG, PA.—The Home Telephone company of Lewisburg has been formed to operate in Union and Northumberland counties; capital, $10,000.

JAMESTOWN, N. Y.—During a severe thunderstorm the switchboard of the telephone exchange caught fire and the apparatus was seriously damaged.

MANISTEE, MICH.—C. T. Ream has been appointed manager of the Manistee Telephone Exchange in place of C. D. Grannis, resigned.

RICHMOND, VA.—A charter has been granted to the Richmond Standard Telephone Company. Their capital stock shall not be less than $100,000, nor more than $300,000, divided into shares of $100 each.

SPIRIT LAKE, IA.—The Spirit Lake Telephone company has sent its articles of incorporation to the secretary of state to be filed. The capital stock is $10,000. Incorporators are W. W. Pritchard, L. H. Farnham, H. E. St. Clair, F. W. Barren, A. B. Funk and seven other citizens.

HONESDALE, PA.—The Citizens' Telephone company expects to have its wires working within a month.

MUSCATINE, IA.—The telephone system here is to be entirely renovated.

SELMA, O.—The Selma Mutual Telephone company has been formed; capital stock, $500.

TIOGA, PA.—The Tioga County Telephone Co. has been formed; capital stock, $1,250.

BARABOO, WIS.—A new telephone system will be built in Baraboo by local capitalists.

CARLTON, TEX.—A movement is on foot to build a telephone line from Carlton to Hico.

MT. PLEASANT, PA.—There has been chartered the Mt. Pleasant Mutual Telephone Co., Westmoreland county; capital stock, $1,000.

LITTLE ROCK, ARK.—The Little Rock exchange of the Southwestern Telegraph and Telephone Company has a new manager—Mr. James A. Chambers, of Dallas, Tex.

MINERAL POINT, WIS.—The Mineral Point Telephone company has been formed; capital, $1,500; incorporators, N. H. Snow, W. R. Smith, Phil Allen, Jr., and others.

NORWICH, N. Y.—Several enterprising citizens are advancing the project of obtaining a telephone line between Norwich and Chenango Lake.

MODESTO, CAL.—The Sunset Telephone company have a crew of men at work making the local connections with the business houses, offices and courthouse and residences in this city.

WAYNE, N. Y.—The Wayne Telephone Exchange have set up their switchboard for the central office in F. R. Freeman's drug store.

PAWTUCKET, R. I.—The officials of the Providence Telephone Company have decided to begin the erection of a building upon the lot on High street the coming fall.

RACINE, WIS., will probably have a new telephone company. It is the Northwestern Telephone and Electric company of Milwaukee. It will use the Ferdinand telephone. One of the organizers of the new company is Mr. J. D. Jillson.

BALTIMORE, MD.—The Chesapeake and Potomac Telephone Company has awarded to Mr. John Hiltz the contract for building an additional story on the telephone building, at St. Paul street.

HUNTINGTON, IND.—Chas. F. S. Neal, Chancellor Commander of the K. of P. of Indiana; Charles N. Zion and Phil Alder of Lebanon, have purchased the Phoenix Telephone Exchange of this city.

OAKLAND, CAL.—The Sunset Telephone and Telegraph Company has issued a new schedule of rates for the long distance telephone service, which shows a great reduction in those which were formerly in effect.

NORTH ENGLISH, IA.—The North English and Green Valley Telephone company have filed articles of incorporation. The principal place of business is at North English, Iowa county. The capital stock is $200.

LOS ANGELES, CAL.—Herman de Laguna has filed an application for a telephone franchise with the City Council. He states that he is representing a competitive company which will lower rates from 50 to 60 per cent.

ELIZABETH, N. J.—The New York and New Jersey Telephone Company, with headquarters at Elizabeth, has decided to equip its inspectors and linemen with bicycles so that they can reach points of trouble on the lines more quickly.

WAUKON, IA.—Articles of incorporation of the Standard Telephone company have been filed at Waukon. The capital stock is $25,000. The incorporators are V. H. Stevens, president; Herman Boeckeh, vice-president; J. J. Dunlevy, secretary; O. J. Hager, treasurer.

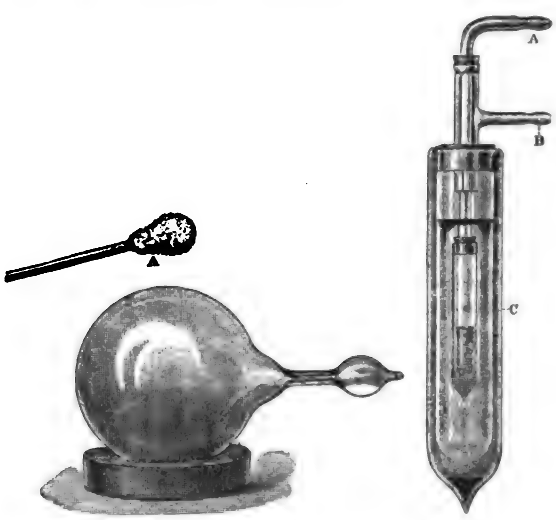
BAY CITY, MICH.—The Common Council has voted to return to the Anthony Telephone Co., of Cincinnati, the certified check for $1,500, which was deposited with the mayor at the time the company was seeking a franchise in Bay City. Under the decision on the Berliner patent case, it is asserted, the company could not carry out its contract with Bay City.

ELIZABETH, N. J.—The Ohio Automatic Telephone and Switch Company has filed articles of incorporation here. The company will begin business with $250,000 capital and will have its start in Elizabeth, with an office in Cleveland, O. The incorporators are Colonel William K. Fogg and William S. Thyng, of Roselle; John W. Lovell, of New York, and Lewis H. Allen, of New Rochelle. The company will make a specialty of the manufacture of the Strowger automatic telephone switch.

SCIENTIFIC USES OF LIQUID AIR.[1]—II.

BY PROF. J. DEWAR, F. R. S.

Here is a globe of the capacity of 1 litre. It has been filled with, presumably, nothing but the vapor of mercury, by boiling under exhaustion and subsequent removal of all excess of liquid. Such a flask ought to contain mercury in the gaseous state that would weigh rather less than one-tenth of a milligramme, assuming the ordinary gaseous laws extend to pressures of less than one-millionth of an atmosphere. Now we know by electric deposition that one-tenth of a milligramme of gold can be made to cover 1 sq. cm. of surface with a fine metallic deposit. Considering the general similarity in the properties of mercury and gold, we should therefore anticipate that if all the mercury vapor could be frozen out of the litre flask it would also form a mirror about 1 sq. cm. in area. But after one such mirror is deposited the renewed application of a second liquid air sponge to another portion of the surface would cause no visible deposit. This is exactly what takes place. If, however, two spheres, one much larger than the other, are joined together by means of a tube about 2mm. in diameter and 50mm. long, the whole space being a Torricellian vacuum (with some excess of mercury) then on decanting, the mercury may be transferred to the smaller sphere, as is represented in Fig. 3. Now if an air sponge is applied to a portion of the surface of the larger sphere, a mercury mirror instantly deposits, but on applying a new air sponge to another portion of the surface, no further mercury mirror is formed. The narrow glass tube prevents the excess of liquid mercury in the small bulb supplying vapor rapidly to the larger one, so that the local cooling to — 180° C. of a portion of the surface has practically condensed all the mercury in the



FIGS. 3 AND 4.

larger space, although the small one is still filled with saturated vapor and a free communication exists between them. If while in this condition the small bulb is inclined so as to allow a drop of liquid mercury to fall into the lower side of the large bulb, which has not been cooled, instant deposition of mercury takes place on the liquid air cooled portion of the upper surface. Under very small pressure of vapor, therefore, equalization of pressure of two bulbs communicating by a narrow tube is a very slow process.

There are cases, however, in which the application of a sponge of liquid air to the surface of a vessel causes no visible deposit, and yet the inference is that something has been condensed. The best arrangement to show this effect is to select highly exhausted vacuum tubes containing phosphorescent materials like alumina and other minerals, and to arrange the induction coil spark gap of a little greater resistance than the vacuum tube. On starting the coil the current passes slowly by the vacuum tube, but immediately the liquid air sponge cools a portion of the surface of the bulb, the discharge shifts to the air-gap. During the cooling the phosphorescence of the glass tube is greatly increased, but finally the resistance may become so great that all discharge in the vacuum tube ceases. Some old tubes belonging to the late Dr. de la Rue have given visible deposits near the electrodes, and in many the diameter and distribution of the striæ are materially changed during the local cooling to —190° C. When large vessels containing nothing but mercury or iodine vapor as a residuum of the vacuum space are rubbed with a cotton wool sponge of liquid air in a dark room, luminous glows filling the vessel take place occasionally, or bright flashes of light which enable the shape of the vessel to be seen. The ordinary mercury vacuum vessels show the same phenomena, which is doubtless due to electric discharges caused by friction and cooling.

The optical properties of bodies cooled to the temperature of boiling liquid air will require long and patient investigation. An interesting fact easily observed is the marked change in color of various bodies. Thus, for instance, oxide, sulphide, iodide of mercury, bichromate of potash, all become yellow or orange, while nitrate of uranium and the double chloride of platinum and ammonium become white. Chromic acid, dilute solution of iodine in alcohol, strong solutions of ferric chloride, and other colored solutions become greatly changed. Such facts are sufficient to prove that the specific absorption of many substances undergoes great changes at the temperature of —190° C.

The tranquil atmosphere of air above the surface of the liquid in cylindrical or spherical vacuum vessels is a convenient place to cool very fragile bodies. During the slow ebullition of the fluid, gas between —190° C. and —180° C. is given off, which has three times the density of ordinary air, and which falls slowly over the mouth of the vessel in a heavy stream. On dipping into this atmosphere small soap bubbles, they contract rapidly and then freeze. If a soap film is made on a circle of thin wire about 3 inches in diameter, and allowed to stand until it shows the various orders of colored bands, and is then carefully dipped into the cool air, it freezes, showing all the original colors. The black band is, however, always broken. Speaking of films, an interesting experiment may be made with a thin stretched sheet of india-rubber, such as is used for making balloons. It is well known that stretched india-rubber contracts when heated and expands when cooled. Now this can be shown very easily by covering a glass funnel or the end of a cylindrical vessel with a stretched sheet of rubber as thin as the walls of balloons. Such a surface is quite flat and fairly transparent. If a sponge of liquid air is drawn across the surface, the course is marked by a series of wrinkles, due to the temporary expansion of the rubber caused by the extreme cold. The sheet of rubber, being extremely thin, soon regains the ordinary temperature, and the surface then is as flat and tense as before. During the continuous motion of the cotton wool liquid air sponge over the rubber surface, it is followed by wave-like depressions, which disappear almost as quickly as they are formed. The elasticity of india-rubber, after cooling to —182° C., and reheating, seems unimpaired.

Organic substances that only become solid at very low temperatures may be divided into two classes: those which crystallize, and those which form glasses. Thus, bisulphide of carbon, tetrachloride of carbon, methyl alcohol, hydride of amyl, all form crystals, whereas ethyl alcohol, amyl alcohol, turpentine, ethyl nitrate, chinoline, picolin, are glass-like. If a few drops of bisulphide of carbon are added to alcohol, and the mixture cooled to —180° C., a white solid emulsion is formed, whereas the addition of tetrachloride of carbon to the alcohol resulted in the production of a clear solid without any separation. In the same way pure methyl alcohol crystallizes easily, but the addition of a few drops of ethyl alcohol prevents crystallization, and causes a glass to be formed. Thus the examination of the behavior of organic bodies at low temperatures may be a fruitful means of organic investigation.

For many purposes of investigation it is necessary to keep liquid air without evaporation. This is readily done by the use of two vacuum test tubes, fitting freely one inside the other, arranged as in Fig 4. The smaller one is filled with liquid air, and after the insertion of an india-rubber stopper and glass tube, is completely immersed in liquid air contained in the larger vacuum vessel. In the figure the tube A connects with the inner vacuum tube and B with the outer. As the latter receives all the radiant and conducted heat, air is continuously boiling off through the tube B; but as the supply of heat is effectually cut off from the inner vacuum vessel, also containing liquid air, no air distills through tube A. This is the most convenient arrangement to use for the production of solid air. For this purpose B is connected with an air pump until the pressure is reduced to about ½ in., and therefore the temperature about—200° C. Then a good air pump is put on to the inner vessel of liquid air (containing oxygen and nitrogen in the normal proportion of oxygen and nitrogen) by means of the tube A, while maintaining constantly the exhaustion in the outer vessel. In a short time the air in the inner vessel solidifies to a transparent jelly-like mass.

TO PURIFY POTTER'S CLAY MAGNETICALLY.

A special dispatch of August 16 from East Liverpool, O., says:—A party of local capitalists is organizing to put into effect a scheme which it is thought will revolutionize two important industries of the Ohio valley. A. C. Wolf and H. A. Whitacre, both of Wellsville, recently brought out an invention for the abstracting of the iron from potter's clay by the use of electro magnets. The new machine has been on trial at one or two potteries and seems to do the work planned for it. The new company proposes to erect a $60,000 factory, which will cleanse the clay of the iron and supply it to the factories. Clay which is now useless owing to the iron in it can be purchased very cheap and the iron extracted. The same thing will be done with the sand used in the glass factories. The glass is often materially damaged by a larger proportion of iron than usual in the sand and there are great beds of the glass sand in Pennsylvania which cannot be used owing to the amount of iron which they contain.

REPORTS OF COMPANIES.

CLOSING OUT THE JAEGER LAMP CO.

Deputy Sheriff Dunphy has sold out the effects of the Jaeger Electric Lamp Company, at No. 154 West Twenty-seventh street New York City, which was incorporated on Feb. 21 last under New Jersey laws with a capital stock of $10,000.

ASSIGNMENT OF THE L DYNAMO CO.

The L Dynamo Company, Limited, a joint partnership organized under the laws of the State of Pennsylvania, has made an assignment for the benefit of creditors to John A. Cass, of Swarthmore, Pa. The deed is signed by John A. Cass, Chairman, and attested by W. E. Jackson, Secretary, and conveys no real estate.

A NEW BUILDING FOR THE COMMERCIAL CABLE.

Mr. Jefferson M. Levy on June 28 purchased the Cutting building, in New Street, New York City, adjoining the Stock Exchange on the south. He already owned the Delmonico and Marshall properties adjoining the southward. On these he announced his intention of erecting a new fire-proof sky-scraper office building. His plan was to incorporate the property and express the value of the new property in bonds and stocks of the corporation. The company which will erect the building has now filed articles of incorporation at Albany. It will be known as the Commercial Cable Building Company, and its capital stock is placed at $1,000,000. John W. Mackay is its President, and other directors and stockholders of the Commercial Cable Company will be in its board of directors. They are: George G. Ward, Albert B. Chandler, William H. Baker, Edward C. Platt, George Clapperton and William W. Cook.

The plans for the new building will be by Harding & Gooch, architects of the Postal Telegraph and other large buildings. They call for a structure in the style of the Renaissance, eighteen stories high, with a dome of three stories more, making twenty-one stories in all, above the basement. The three lower stories are to be in white marble, the rest in gray brick and terra cotta. An arcade will extend through the building from Broad to New Street, and there will be a side hallway from this arcade into the Stock Exchange, it is said. The chief object, however, is to provide a suitable permanent home for the cable operating staff. In the absence of Mr. Mackay, the negotiations have been carried through by Vice-President George G. Ward.

OBITUARY.

W. A. HAMMER.

We regret to note the sudden death, in the White Mountains, at the age of 68, of Mr. W. A. Hammer, the father of Messrs. W. J. and Edwin W. Hammer, both electrical engineers. Mr. Hammer was interested in the management of the Theological Seminary of the Reformed Episcopal Church, at Philadelphia, having been one of the founders of that body and at one time president of its synod. His widow is president of the W. C. T. U. of Pennsylvania.

JASON M. BOWEN.

The death is announced of Mr. J. M. Bowen, president of the Portland, Conn., Electric Light Co., caused by the accidental discharge of his gun while testing it at his summer home on Contentment Island, Conn. He was a graduate of Oberlin College and was 65 years of age.

R. H. GALLAHER.

A well known Wall street man disappears by the death of Mr. Robert H. Gallaher. He was known at one time through his large interest in the Gold & Stock Telegraph Co. and his efforts to get tickers introduced in the stock and banking district.

THE FATE OF ONE MUNICIPAL PLANT TOWN.

A special dispatch of August 14 from Wichita, Kan. says: J. M. Davis, of Greensburg, Kan., who was a member of the dual State Legislature during the memorable sessions of 1893, in an interview to-day stated that the population of that town had dwindled from 2,500 five years ago to 125.

The bonded indebtedness of the city incurred in the establishment of water works, electric lighting and other internal improvements is $45,000. Farmers have bought up the majority of the houses for a song and moved them away, and the handful of people that still remain refuse to pay taxes. The outstanding bonds are worthless.

LEGAL NOTES.

A CURIOUS ELECTRIC LIGHT ACCIDENT.

In Grand Rapids, Mich., Judge Adsit has appointed William S. Walker as next friend of little Florence D. Walker, 8 years of age, in order to commence suit against the Grand Rapids Electric Light and Power Company for $10,000 damages for the loss of an eye of the little child. The declaration states that on last December 28 Florence D. Walker was playing at a street corner when an electric light tender threw a burned carbon from the top of the electric tower, 150 feet, to the ground, striking the child in the right eye, tearing loose the iris, separating it from the ciliary body and destroying her sight. The declaration charges the company with criminal negligence and demands $10,000 damage. The carbon was six inches in length and was thrown, as is substantiated by the fact that it struck thirty-five feet from the base of the tower.

EDISON ENJOINED FROM SENDING KINETOPHONES ABROAD.

At Newark, N. J., on Aug. 20, Vice-Chancellor Emory, in Chancery, listened to an argument in an application for a preliminary injunction restraining Thomas A. Edison from sending abroad any kinetophones. The application was granted.

CURIOUS LIGHTING SITUATION AT BLACKSTONE, MASS.

The electric light company at Woonsocket, R. I., has received a formal order from the Massachusetts gas and electric light commission, ordering it to furnish lights to the town of Blackstone at 42 cents a light instead of 50, the price under the old contract.

The electric light company has refused and the matter will probably be settled in the Massachusetts courts. The curious feature of the situation is that the order from the Massachusetts State Commission is addressed to a Rhode Island corporation.

AM. BELL vs. CENTURY AND BAY STATE COMPANIES.

The American Bell Telephone Co., have entered suit against the Century Telephone Co. and the Bay State Telephone Co., both of Boston, for infringement of the Berliner patent.

MISCELLANEOUS.

THE INCANDESCENT GAS BURNER AND STREET VIBRATION.

REFERRING to the use of the Welsbach light for street purposes, the *Gas World* remarks in a recent issue that "The general opinion among Continental engineers appears to be that while the gas consumption is lessened the cost of renewing mantles more than counterbalances the saving in gas: they admit the better light but recognize no monetary advantage. This may be quite true; and if it is, then what has to be done to make the Welsbach an economical street illuminator is to insure a longer life for the mantles. This might be done in two ways—either by making the mantle less fragile than it is at present, or by introducing some contrivance that would protect it from the vibration inseparable from our public streets; or it may be that the end may be attained partly in the one way and partly in the other. A few weeks ago we briefly described a contrivance introduced by the Incandescent Gas Light Company with the object of protecting the mantle from vibration, the device consisting of carrying the mantle gallery upon three springs. That device, as we then showed, had given very promising results, reducing the mantle breakages by 90 per cent. But even after that great reduction the breakages in the particular case referred to were very heavy, amounting, as our correspondent, 'A Northern Subscriber,' pointed out last week, to almost 29 mantles per annum. To renew a mantle 29 times in the course of a year would, it need hardly be said, be a very heavy burden upon the system. This week we have seen another vibration-absorbing device which promises to give still better results."

AN ILLUMINATED ORANGE TOWER.

Mr. J. A. Gorman, Manager of the California Building, at the Atlanta Exposition, has received from the Chamber of Commerce Los Angeles, a communication saying that an orange tower, thirty-five feet high will be erected in the centre of the building, and will be illuminated by means of three hundred incandescent electric lights. The tower will be covered entirely with oranges, which will be kept fresh during the entire Exposition. For that purpose five carloads of oranges have been placed in cold storage at Los Angeles and supplies will be shipped once every fifteen days to replenish the exhibit.

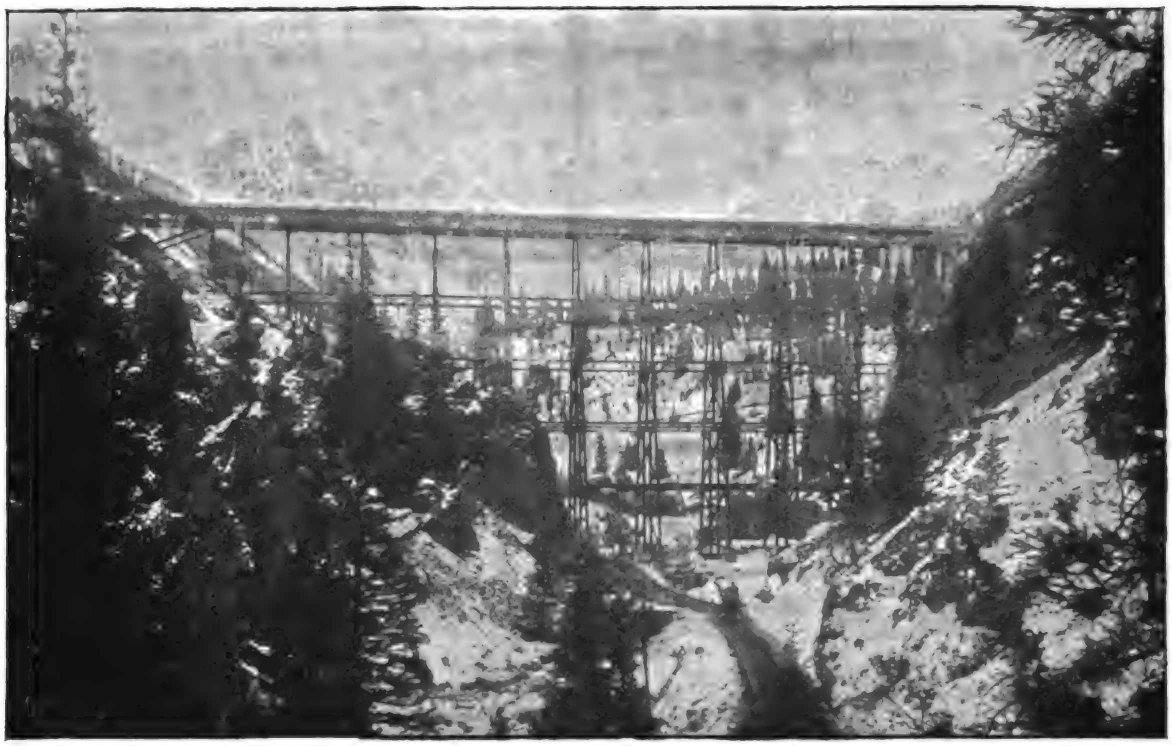


FIG. 1.—FLUME AND TRESTLE, SILVER LAKE MINES, COL., THREE-PHASE TRANSMISSION PLANT.

THREE-PHASE TRANSMISSION PLANT AT THE SILVER LAKE, COL., MINES.

AN interesting application of the three-phase system of long distance transmission of power has recently been carried out at the Silver Lake Mines, near Silverton, Col. where power is transmitted a distance of three miles through some of the roughest country in Colorado. It is attracting considerable attention among mining men, as it is the first three-phase plant installed in the Rocky Mountain region.

The Silver Lake group of mines owned by Edward G. Stoiber, lie about four miles southeast of Silverton, and are situated at an altitude of 12,800 feet above sea level. The ore mined carrie both gold and silver, is of a comparatively low grade and requires concentration. Previous to the installation of electricity, the mill which is situated on the shores of the Lake, near the mouth of the mine tunnel, was run by steam. Coal was brought to the steam engine by a tedious path up the mountain, and by the time it reached the furnace cost $8.75 a ton. This represented a monthly expenditure of almost a thousand dollars, and the expense proved a burden which went far to eat up the profits of the mine. A change, therefore, became imperative.

The plant is now operated by water power, which is brought from the Animas River, above Silverton, through a 8 x 4 foot flume 9,750 feet in length, which carries 2850 cubic feet of water sper minute. The flume and trestle are shown in the accompany-

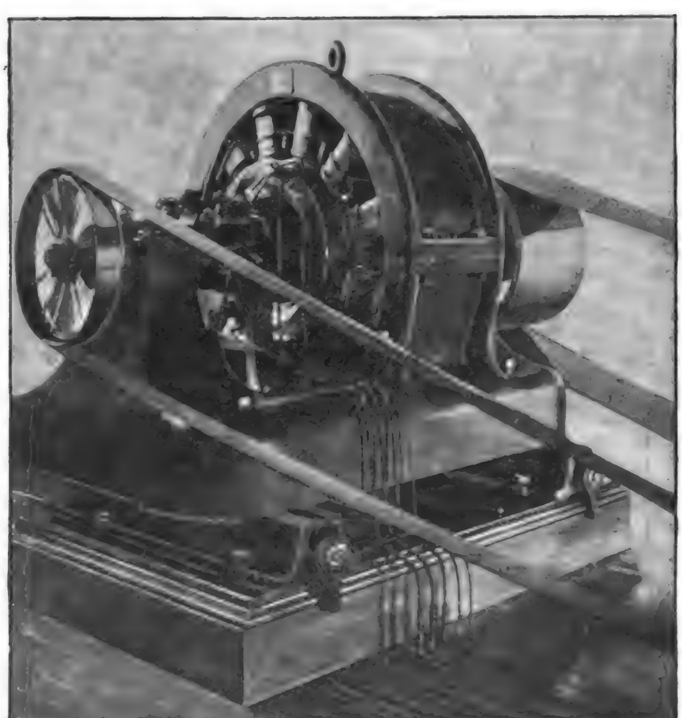

FIG. 2.—THREE-PHASE GENERATOR, SILVER LAKE MINES, COL.

FIG. 3.—POWER HOUSE, SILVER LAKE MINES, COL.

ing engraving Fig. 1. One of the great advantages of electrical utilization is here demonstrated for it was found less expensive to build this costly two mile flume, running from above Silverton down to a spot where the necessary head could be utilized, and then to transmit the electricity back to the mine, rather than to continue to burn coal at the price which it brought at the mouth of the Silver Lake Mines. The head of water obtained is about 180 feet, which develops on the water-wheel shaft 640 H. P.

The plant consists of two 4-foot double-nozzle Pelton water wheels with special buckets belt connected to two 150 K. W. General Electric three-phase generators, one of which is shown in Fig. 2. The current from these machines is delivered at 2,500 volts and is transmitted over a distance a little more than three miles to the Silver Lake mill and mine.

The conductors are No. 3 B. & S. bare copper wires, one for each branch of the three-phase circuits. These are strung from the power house, shown in Fig. 3, up the mountain passes and through the rugged country. In one place where a chasm has to be spanned the wires are strung on poles 275 feet apart. The conductors have been strung with especial care as required by the abnormal conditions. At each insulator the wire is run through a short piece of rubber tube as an extra precaution against leakage. Lightning arresters are placed at each end of the line and an additional safeguard against damage by lightning is provided in the shape of a barbed iron wire which extends the entire distance of the line along the tops of the poles and is grounded at every second pole.

Arriving at the mine the current is supplied to a 100 H. P. three-phase induction motor run directly from the primary circuit. Another 100 H. P. motor, as well as one of 75 H. P. are located beneath the ground and current is supplied to these at a pressure of 220 volts, the reduction in pressure being effected by step-down transformers. In addition, a 15 H. P. motor runs a pump raising water from the Lake to the mill, and one small 1 H. P. motor operates a blower and the lights for a bunk, office and other buildings, both being connected to the secondaries. The General Electric induction motors are used.

The interest in this mine centres, of course, upon the economy effected by the electrical installation. The power used in the mill and the mines at the present time, is more than three times as much as that generated by the steam engine previously employed.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUG. 20, 1895.

Accumulators :—

Secondary Battery, F. King, London, Eng., 544,678 Filed Apl. 5, 1895.
Details of construction referring to the shape of the grids and method of maintaining the plates in position.

Alarms and Signals :—

Automatic Electrical Railway Signal, C. R. Alsop, Middletown, Conn., 544,647. Filed Oct. 22, 1894.
Railway Signal, W. B. Vansize, New York, 544,802. Filed July 18, 1895.
The object of the invention is to obviate the effects of atmospheric electricity in the signal circuit and to guard against the mishaps likely to follow the failure of the relay to operate for any reason whatsoever.
Ship's Telegraphic Apparatus, J. K. Adelsberg, Liverpool, Eng., 544,876. Filed Mch. 16, 1895.
Improvements in the arrangements of the magnets.
Fire Extinguisher, W. Harkness, New York, 544,894. Filed Aug. 13, 1888.
A system of automatic electric signals to indicate in which portion of the building the fire is taking place, and also a signal to indicate when the water in the elevated tank has reached a certain point below which it is not desirable to have the water go.
Electric Train Signal, F. C. E. Von Sternberg, Brooklyn, N. Y., 544,987. Filed Apl. 13, 1895.
Specially adapted for elevated electric and cable railways.

Conductors, Conduits and Insulators :—

Manhole for Electric Cable or Other Subways, E. L. Ransome, Chicago, Ill., 544,747. Filed Jan. 11, 1895.
Consists of a movable shield, hood, or cover in combination with the chamber of the manhole, for the purpose of protecting the electric wires or cables where they are placed about the walls within the manhole chamber.
Insulator for Electric or Other Wires, C. Sproat and E. N. Tarr, Taunton, Mass., 544,778. Filed Jan. 2, 1895.
Insulator is in two screw parts which hold the wire in place without tie wires.
Insulator, R. G. Collins and F. W. Foley, Dollar Bay, Mich., 544,930. Filed Feb. 25, 1895.
The wire is fastened without being bent at the place where it is supported by the insulator.

Dynamos and Motors :—

Electric Motor, B P. Remy, Peru, Ind., 544,749. Filed Nov. 24, 1894.
The motor has an armature of the radial pole type revolving in an elliptical field magnet frame.
Carbon Brush Holder for Dynamo Electric Machines, A. J. Churchyard, Brooklyn, N. Y., 544,844. Filed May 14, 1894.

Electrometallurgy :—

Apparatus for Electroplating, F. and F. H. Engelhard, Springfield, Mass., 544,663. Filed March 23, 1892.
The anode and cathode are continually revolved.

Miscellaneous :—

Dynamometric Governor, W. N. Smith, Chicago, Ill., 544,696. Filed Aug. 16, 1894.
The combination with a prime motor and a dynamo operated thereby and supplying an electric circuit, of air compressing mechanism connected with and operated by the prime motor and an electrical dynamometer lying in said circuit and connected with and controlling the operation of said air compressing mechanism, whereby the rate of compression of air thereby may vary with the current passing through the dynamometer.
Electrically Controlled Weighing Machine, L. H. Nutting, Davenport, Ia., 544,745. Filed Nov. 13, 1894.
Applying Power at a Distance by Means of Electricity, J. F. McLaughlin, Philadelphia, Pa., 544,861. Filed Oct. 8, 1891.
Apparatus for stopping machinery at a distance. Clutches are released by means of an electric motor.
Operating Throttle Valves of Engines, C. H. Silverwood & J. Fraser, Philadelphia, Pa., 544,867. Filed May 21, 1895.
Apparatus for automatically closing throttle valves of engines and other motors from a distance.
Electrically Controlled Winding Mechanism for Time-Locks, W. H. Hollar, Philadelphia, Pa., G. L. Weaver, Boston, Mass., and A. Kennedy, Charlestown, W. Va., 545,020. Filed Apl. 1, 1895.
Electric Winder for Time-Locks, W. H. Hollar, Philadelphia, Pa., G. L. Weaver, Boston, Mass., and A. Kennedy, Charlestown, W. Va., 545,021. Filed Apl. 17, 1895.
Permits the rewinding of the clock movement of the time-lock without opening the safe or otherwise exposing the lock mechanism.

Railways and Appliances :

Trolley Arm and Attachment Therefor, G. Maag, Newark, N. J., 544,677. Filed Dec. 12, 1894.
Device to restrain the trolley wheel from jumping the trolley wire.
Electric Locomotive, E. H. Porter, Radford, Va., 544,685. Filed June 22, 1894.
The armature transmits motion by means of a crank and a connecting rod, and the speed ratio of transmission can be varied.
Automatic Safety Trolley, J. B. Scranton, New Haven, Conn., 544,774. Filed Mch. 30, 1895.
Trolley Arm and Wire Finder, F. W. Riess, Philadelphia, Pa., 544,794. Filed June 10, 1895.
Electric Railway, J. F. McLaughlin, Philadelphia, Pa., 544,862. Filed Apl. 17, 1895.
Has reference to improvements in electric railways in which exposed contacts on the surface of the road-beds are coupled to a buried supply conductor by underground switches operated by magnetic attraction from the motor car.
Electric Railway, J. F. McLaughlin, Philadelphia, Pa., 544,863. Filed May 8, 1895.
An underground switch which will be positively locked when in the open position, and which will be unlocked and closed only when covered by a motor car.
Trolley, G. W. Biddell, Chattanooga, Tenn., 545,009. Filed Feb. 2, 1895.

Switches, Cut Outs, etc. :—

Electric Elevator, N. O. Lindstrom, Union Course, N. Y., 544,768 Filed May 16, 1895.
A switch especially adapted for operating and controlling elevators.
Electric Switch, T. H Brady, New Britain, Conn., 544,781. Filed May 8, 1895.
One of the contact jaws is pressed against the knife blade by a spring.
Multiple Electric Circuit and Mechanism for Maintaining Same, T. K. Ames & E. A. Parker, Peterborough, N. H., 545,005. Filed Oct. 19, 1894.
Device whereby an electric current may be caused to supply in succession a number of independent circuits. A distributing switch.

Telephones :—

Telephone Switch and System, E. C. Wilcox, Meriden, Conn., 544,711. Filed May 13, 1895.
A hand operated transmitter switch.
Magneto Electrical Telephone, M. Frank, Munich, Germany, 544,890. Filed June 30, 1894.
The permanent magnet is surrounded by a steel shell acting as a handle, and forming a closed magnetic circuit.
Telephone-Exchange Apparatus, J. J. O'Connell, Chicago, Ill., 544,901. Filed Apl. 29, 1893.
When the operator shifts a key to throw her head-telephone into or out of a subscriber's circuit the signal at the chief operator's desk indicates such fact.

THE GROWING USE OF MEDBERY FIBERITE.

MR. H. J. MEDBERY, President of the Fiberite company, manufacturers of the Medbery overhead material and other specialties, has just returned from Chicago, and reports a most encouraging outlook for the trade in that section of the country. He feels assured that his company will be able to secure a good share of the business. For several years Mr. Medbery has held to his determination to make the highest grade of overhead material possible. The fact of there being a large quantity of cheap material used, has tempted him at times to compete with such material, but he had sufficient pride in the name of "Medbery" and faith enough in the future of good, honest material, to refuse to go far into such lines. His company is now reaping the benefit of his determination to make "the highest grade material only." Mr. Medbery states that roads "all over the country, and almost without exception, are demanding material which has been tried, and found equal to the severe conditions of an electric road." The company has confidence enough in its material to give the purchaser an absolute guarantee, although wherever the Medbery has been used, such guarantee is not necessary. Honorable business methods, combined with honest goods, has resulted in the factory of the Medbery Company being rushed to the utmost to fill orders. The Medbery Company is represented in New York, Chicago, San Francisco, Philadelphia and other cities by concerns of well-known standing, and orders are filled at once from stocks carried at these agencies.

NIGHTINGALE, JOHNSON & CO.

MR. WALTER H. MORTON, formerly foreman of the Testing and Expert Department, General Electric Co., Schenectady, N. Y., has been admitted to full partnership in the firm of Nightingale & Johnson, electrical engineers and contractors, Utica, N. Y., and the firm will continue its rapidly increasing business under the name of Nightingale, Johnson & Co.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE DEMAND FOR BEACON INCANDESCENT LAMPS.

The Beacon Lamp Co. of Boston, report having closed a contract with the Boston Electric Light Co. for 9,000 lamps, to be used in connection with the Knights Templars' decorations, in which some of the pieces require several hundred lamps, the idea being to outdo any previous efforts in this direction. Keith's Theatre has ordered 1,000 special lamps for the same purpose.

The Beacon Co. have also been awarded the U. S. Government contract for 10,600 lamps for the Brooklyn Navy Yard, so that altogether with its regular run of orders the company is quite busy.

ACTIVITY OF THE WESTINGHOUSE MACHINE CO.

The Westinghouse Machine Company reports business active and the outlook very flattering. Orders for compound engines the past month, include one 250 H. P. to Whittenton Mfg. Co., Taunton, Mass.; one 100 H. P. and one 125 H. P. to American Hydraulic Dredging Co., East Douglas, Mass.; one 80 H. P. and one 100 H. P. to Sioux Consolidated Mining Co., Mammoth, Utah; one 200 H. P. to Wendell & Smith, Overbrook, Pa.; two 80 H. P. to Upper Peninsula Hospital for the Insane, Newberry, Mich.; four 250 H. P. to United States Capitol Building, Washington, D. C.; one 250 H. P. to Connellsville Electric Light Co., Connellsville, Pa.; one 250 H. P. to Belvidere (Ill.) Electric Company; three 160 H. P. to Carnegie Library Building, Pittsburg, Pa.; one 125 H. P. to Hackensack (N. J.) Gas & Electric Company; one 300 H. P. to Wilkinsburg (Pa.) Electric Company; one 250 H. P. to Sing Sing (N. Y.) Electric Company; one 200 H. P. to Gloversville (N. Y.) Electric Company. In addition to the above, the increased number of orders for "Standard" and "Junior" automatic engines, indicates a general revival in all branches of manufacturing.

TELEPHONES FOR THE NAVY DEPARTMENT.

The Navy Department, through the Bureau of Yards and Docks, is inviting proposals until September 16, for telephones and switchboards.

THE "ELECTRA" NUERNBERG CARBONS FOR THE ATLANTA EXPOSITION.

MR. HUGO REISINGER, of 38 Beaver Street, New York, sole importer of the "Electra" Nuernberg Carbons, informs us that the contract for the supply of high grade arc light carbons, for lighting the Atlanta Cotton States and International Exposition, has been awarded to him.

Mr. Charles F. Foster, the engineer of the Departments of Machinery and Electricity, in his requirements, states that the carbons must be first-class in every respect; and being for exposition work, should burn as perfectly as possible.

After having made an exhaustive test of various other imported carbons, Mr. Foster decided to adopt the "Electra" carbon, it having proved far superior to any other carbons tested.

NEW YORK NOTES.

MR. J. H. VAIL has been appointed Consulting Electrical and Mechanical Engineer to the State Mutual Life Assurance Company, Worcester, Mass., and is now preparing plans and specifications for a complete steam and electric plant of the best type for the service required.

MR. H. W. WELLER, C. E., E. E., late of the General Electric and Columbian Electric Companies, has been appointed manager in New England, with headquarters at Boston, for the Campbell & Zell Co., the makers of the Improved Zell Safety Water Tube Boiler, a plant of which has just been ordered for the Tremont Temple, Boston.

MR. FREDERICK NOLL, late of the firm of Noll & Sibley, has joined the forces of the Interior Conduit & Insulation Co., and will manage the sales of their dynamos, motors, fans, conduits, etc., for the metropolitan district of New York. He has been actively connected with the electrical trade in this vicinity for fifteen years and enjoys a large friendship and acquaintance.

THE ABENDROTH & ROOT MANUFACTURING COMPANY has of late filled a number of notable orders for their improved Root water tube boiler, principally in New York City and vicinity. It may be mentioned in this connection that Arthur Loretz, Jr., formerly New York manager for the National Water Tube Boiler Co., is now representing the "Root" boiler at 28 Cliff street, New York City.

WESTERN NOTES.

MR. H. J. MEDBERY, Pres. of the Fiberite Co., Mechanicville, N. Y., was a recent visitor to Chicago where he was heartily welcomed by his many friends.

THE RACINE HARDWARE CO., of Racine, Wis., are still very busy, and are shipping quite a number of their well known vertical and horizontal engines.

THE BELDING ELECTRIC ALARM MAIL BOX CO. report a good business. They have placed their boxes in several of the new buildings in Chicago, and are also receiving some nice orders from various parts of the States.

THE ELECTRIC APPLIANCE COMPANY has secured some very handsome orders for Upton Arc Lamps for which they are General Western Agents. The alternating lamp with their patent "anti-hum" cover is proving very popular, as it does away almost entirely with the noise of the lamp, which has always been such an objectionable feature in alternating lamps.

THE ELECTRIC APPLIANCE COMPANY is sending out an advertising novelty in the shape of a printed wiring table that can be cut to fit inside the cover of a watch case and is known as the Wells Watch Case Wiring Table. The Company has sent out several thousand of these and will be glad to receive applications from any of the trade that have not received them. They are mailed free on application.

THE METROPOLITAN ELECTRIC COMPANY, Chicago, have been appointed selling agents for the Coe Electric Alarm Mail Box. This box is the latest improvement in the postal service. By a simple device the act of inserting the letter rings the house bell a predetermined length and number of times, thus distinguishing the postman from a caller. It requires no extra wiring, battery or bell. The Metropolitan Company state that they are in position to fill orders for this box in three different styles and in any finish.

WISCONSIN RIVER.—The new mills of the Grand Rapids Pulp and Paper Co., at Bearin, on the Wisconsin River, is being rapidly pushed forward. The company is constructing a dam, excavating a large mill pit from solid rock, and erecting large substantial brick buildings. They have contracted with The James Leffel & Co., of Springfield, Ohio, for 15 of their large Samson turbine water wheels, which will be in position in November. All the work is being done upon the most approved plan, and is of the most substantial character.

MR. L. A. FARNSWORTH, Chicago manager for the Automatic Circuit Breaker Co. of Newaygo, Mich., has just returned from a trip through Michigan and Wisconsin and reports a number of good orders for their circuit breaker. He thinks that the outlook for the future business is very promising. Mr. Farnsworth is located at No. 937 Monadnock Bld. and will always carry on hand a full line of circuit breakers so that all orders will be filled on short notice. The new catalogue entitled, "Protection For Sale" is now in press and will be cheerfully given to all who ask or send for it.

PHILADELPHIA NOTES.

THE PENNSYLVANIA ELECTRIC ENGINEERING CO. has been awarded the contract for the complete wiring and construction work for the Fidelity Mutual Life Association building at Broad and Arch Sts. The specifications call for a plant of 3,000 light capacity. General Electric dynamos and M. A. Greene engines will be used.

NEW ENGLAND NOTES.

BROWN & SHARPE MFG. CO., of Providence, R. I., have issued in very complete form their 1895 catalogue and price lists. The volume is necessarily bulky, covering, as it does, their many departments, among which are machinery, sewing machines and iron castings. The illustrations also include milling, grinding, screw and tapping machines, vertical and horizontal chucking machines, gear cutting machines, engine and hand lathes; also a full list of articles for cotton and woolen manufacturers' use.

THE DELAWARE HARD FIBRE CO. of Wilmington, Del., has secured the contract just awarded for supplying the General Electric Co. with fibre. They are the largest consumers of this material in the world and their trade is the big thing in the fibre line. The Delaware Hard Fibre Co. have recently more than doubled the size of their plant and are running day and night.

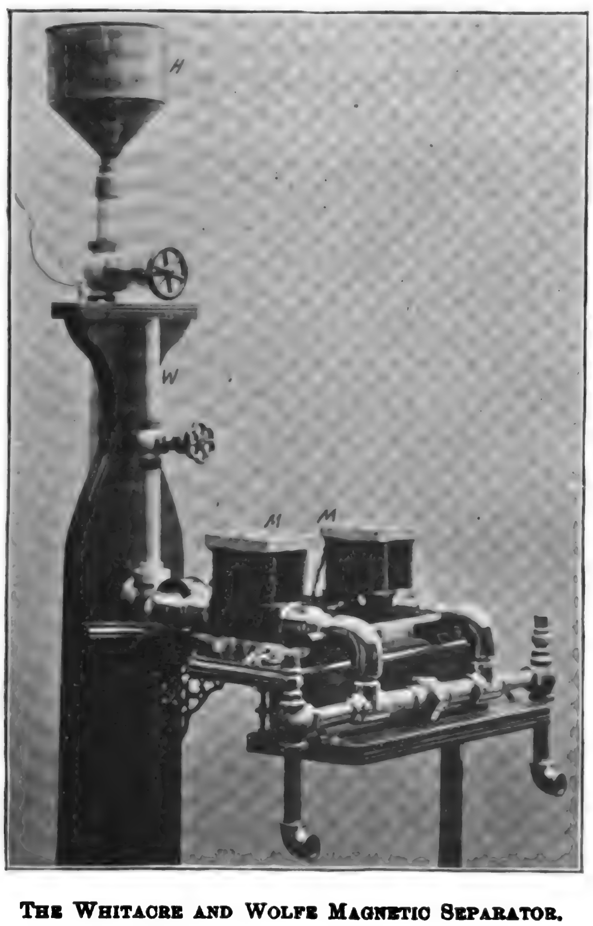
☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XX. SEPTEMBER 4, 1895. No. 383.

THE WHITACRE-WOLFE IRON SEPARATOR FOR CLAYS AND ORES.

DEPOSITS of clay are found in many localities but there are comparatively few that are sufficiently pure to permit of their being used for pottery ware. The most common impurity met with in clay is iron, and the endeavor to remove this has called forth a variety of devices. A magnetic apparatus naturally suggests itself immediately to accomplish the desired object, but the nature of the



THE WHITACRE AND WOLFE MAGNETIC SEPARATOR.

material to be handled calls for special treatment, as even a small trace of iron will make its presence known in the pottery ware when finished With these difficult conditions in mind, Messrs. Whitacre and Wolfe, of Wellsville, Ohio, have recently completed and put in operation the separator illustrated in the accompanying engraving, the construction of which will be readily understood.

The material to be purified is fed into the hopper H, in the form of "slip" or liquid, and passes down the pipe to a tee, from which two branch pipes proceed, one going horizontally to the right, and one to the left. At the point where each branch starts, it is surrounded by a coil having a hollow soft iron core with pole pieces. One of these coils is seen in the illustration at C. The pipes then make a bend and pass forward through the magnetic fields produced by the bipolar magnets M M and then bend downwards like faucets, the material passing off through the pipes shown.

The clay fed into the hopper, passes down the pipes, which are all of brass, 2 inches in diameter, and as it reaches the coils C the iron particles held in suspension are retained. Such particles as are not held by the coils C then come under the influence of the magnets M M, which successfully retard their progress.

When sufficient iron has been extracted to necessitate a cleaning of the machine, the current is cut off from the coils and magnets, and all the valves are closed except the one leading to the pipe which conveys the extracted iron to the sewer. The pipes and accumulated iron are then readily cleaned by the wash-out pipe shown at W. This pipe can also be used for tempering the material to any desired consistency, while the machine is in operation, by permitting more or less water to pass through.

In order to guard against a failure of the current and hence accidental demagnetization of the magnets, an alarm is arranged to give a signal by the closing of a local bell circuit.

The separator, which is the joint invention of Mr. W. W. Whitacre and Mr. A. C. Wolfe, has already been at work and is pronounced highly efficient by the leading potters in the largest pottery district of the country. We understand that the machine is also to be used in the magnetic purification of gold, silver and copper ores, and in the extraction of iron from the sand used for glass making.

THE DURABILITY OF PORCELAIN AS AN INSULATOR.

BY A. B. DOBBS.

As an insulator, porcelain is a great deal tougher and more lasting than glass, and, while new, a higher insulation is claimed for it even when covered with dust and smoke. But in an experience extending over several years with all kinds of insulators, I have noticed that the glazing on the porcelain seems to crack when exposed to the weather.

A case of this kind came under my notice about two years ago. The original telegraph line from Montreal to Vancouver is strung on porcelain insulators of the same size and shape as the glass insulator, known in this country as the W. U. double petticoat pattern. Upon inquiry I was told that the porcelain insulators were not considered as good as glass (all the other wires on the line were tied to glass). I could see for myself that the wire in contact with the porcelain in many places left red streaks of rust upon it, proving that either the porcelain contained some deleterious substance, or that there was slight electrolysis, caused by leaks. The insulators were also seamed and badly cracked. In justice, however, I will say that the porcelain appeared to me to be of Canadian manufacture, which is of a very inferior quality.

It will be interesting to learn how porcelain insulators that have been in place from five to ten years have behaved; the record to include the condition of the climate in which

they are worked and whether of American or foreign manufacture.

There is a growing impression, that for high voltages at least, porcelain is better than glass; but *is* it?

THERMO ELECTRIC CURRENTS FROM GALENA.

BY AN EXPERIMENTER.

In the old table prepared by Prof. Cumming showing the position of the various metals in a thermo electric series, galena is placed at the head of the list as being positive to all others. It was also used by Clamond, Stefan and probably by others for the positive element of thermo electric batteries. It is undoubtedly true that it almost invariably does give a positive current but still specimens have been found that are sometimes positive and sometimes negative. This being the case, it becomes an interesting question as to what causes the reversal of the current and under what conditions it can be made to give a positive or negative as desired. With this object in view the following experiments have been made and repeated many times with the same result every time.

A strip of lead foil about four inches long, one inch wide and two one-hundreths of an inch thick, was covered on one side with finely powdered sulphur and rolled up into a solid cylinder about one inch long. It was then put into a glass tube the inside diameter of which was just large enough to allow it to fit inside loosely. The tube was then heated over a Bunsen burner. Part of the sulphur combined with the lead, which became red hot from the heat caused by the chemical action. The rest of the sulphur was melted and partly vaporized. It was then removed from the flame and after a while the lead was pushed out of the tube and was found to be a somewhat porous mass of lead sulphide or artificial galena, thoroughly saturated with sulphur.

A piece of platinum wire was then melted into one end of it and connected to a galvanometer. Another platinum wire also connected to the galvanometer was pressed against the other end and heated red hot. It gave a negative current flowing from the hot wire to the sulphide. It also melted the sulphide and decomposed it, the released sulphur burning off and the lead recombining again with the free sulphur on the cold side. This action was constant as long as the sulphide was saturated with sulphur, but the heat gradually drove off the free sulphur and then the current reversed and flowed from the sulphide to the hot wire.

A cylinder of sulphide was then made in the same manner as before and placed in a glass tube, the inside diameter of which was somewhat larger than the cylinder, so as to allow a free passage to the air. The tube was then held over a flame and all surplus sulphur driven off. It was then connected to the galvanometer and tested as before and at once gave a positive current flowing from the sulphide to the hot wire. In this case the oxygen of the air probably combined with the sulphur which passed off as sulphurous acid and also with the lead, forming an oxide. This oxide was then decomposed by the hot wire, the lead flowing out on to the wire and the oxygen combining with the sulphide on the cold side. Litharge, when melted and formed into a cylinder and tested in the manner described above also gave a positive current. It was also decomposed, the melted lead flowing out on to the hot wire.

A piece of natural galena was tested with the hot wire and found to give a positive current. It was then heated in melted sulphur and when tested again gave a negative current for some time, but after the heat had expelled the sulphur the current reversed and became positive again.

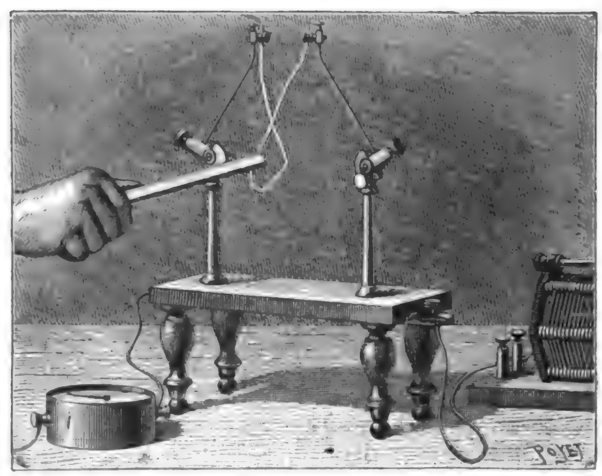
A cylinder of the sulphide saturated with sulphur was pressed against one end of a short piece of platinum wire about $\frac{1}{8}$ of an inch in diameter, and another cylinder, from which the surplus sulphur had been expelled, was pressed against the other end, and, the wire between the two being heated red hot, a positive current flowed from the cylinder from which the sulphur had been expelled, to the hot wire; and a negative current from the hot wire to the cylinder which was saturated with sulphur. These two currents joined together and doubled the electromotive force and also confined the heat of the wire so that it could not escape at either end without giving up its equivalent in current.

These experiments would seem to show that the action is the same as in any voltaic cell, the direction of the current being determined by the nature of the chemical action which takes place under the varying conditions.

No attempt has been made to measure the electromotive force of the current, but the cylinders of sulphide will be gladly furnished all ready for testing to anyone who has the facilities for making exact measurements and who may wish to do so.

ACTION OF THE ELECTRIC CURRENT ON ALUMINUM WIRE.[1]

If an aluminum wire has a current passed through it sufficiently strong to heat it beyond the point of fusion it is observed that it can be carried to a white heat and maintained in this state, contrary to what is observed in other metals submitted to the same test, which, when their points of fusion are obtained melt instantly, each end of the ruptured wire presenting the form of a small metallic



EXPERIMENT WITH HOT ALUMINUM WIRE.

globule produced by the contraction due to the surface tension of the liquefied metal.

Aluminum behaves very differently. If the wire be originally strung taut between the two supports that carry the current, it sags heavily, but can remain quite a long time in a state of complete incandescence up to the moment of rupture, which generally takes place close to the clamps. The aluminum wire evidently consists of a liquid thread which oscillates at the slightest breath, and is maintained in the air by the cohesion of its molecules, and probably also in virtue of the formation of a very thin skin of alumina, which acts the part of an infusible protecting coating around the fused metal. This coat must in any case be very thin, for microscopic examination does not show very strong indications of oxidation.

The results of a series of tests carried out in air with aluminum wires of different lengths and diameters show that the aluminum conveys rapidly to the supports a part of the heat liberated, and that for decreasing lengths of wire increasing current strengths are required to bring them to the same temperature. Thus, for example, it was shown that a filament of aluminum 0.5 mm. in

1. Abstract from *La Nature*.

diameter is able to convey the very extraordinary current of 31 amperes, at which point it is at a reddish white heat. The resistivity of the wire increases in a rapid ratio, since for the same wire, the difference of potential at the extremities is almost zero at the start, with the current hardly sufficient to heat the metal appreciably, but increases rapidly, reaching the value of 5 volts, when a white heat is attained.

The mobility of the aluminum wire at a white heat is well shown by the experiment illustrated in the accompanying engraving. A wire 25 to 30 centimetres long and 0.3 mm. in diameter is arranged so that its lower end can be given a turn. This turn, when current passes, is extremely sensitive to the approach of a straight magnet, and depending upon the direction of the current, the pole of the magnet is violently repelled or attracted. In general—and it is at this point that the experiment becomes the most attractive—the repulsion changes into sudden torsion of the wire on itself, which tends naturally to present to the pole of the magnet the side in which the direction of the current is such that attraction is produced. The experiment however, is of short duration, for at this instant, the rapid twist brings the two sides of the turn in contact, and in consequence short circuits the part of the wire below the contact point. The result is a rapid increase of the current which instantly fuses the wire.

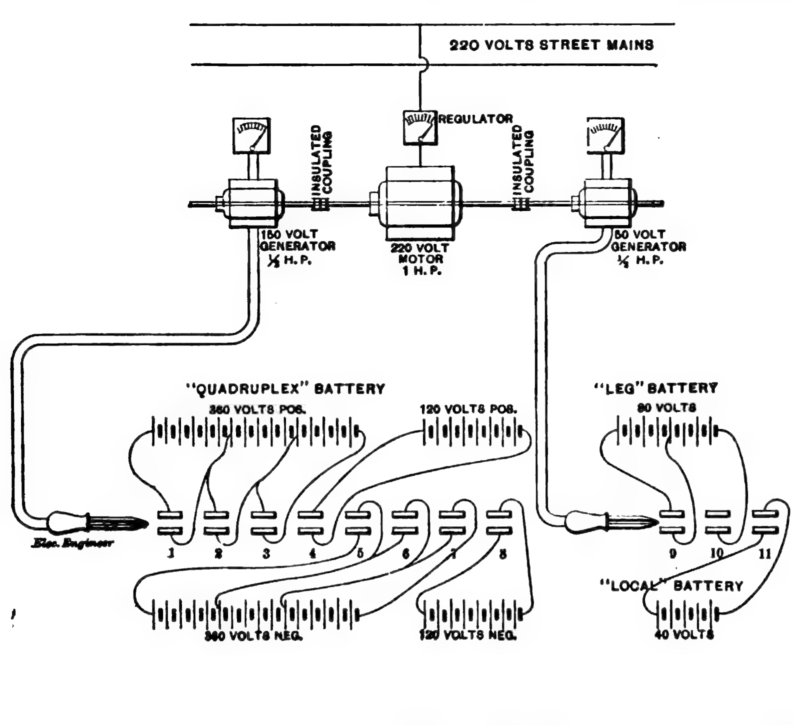
ELECTRICAL UTILIZATION OF THE RHONE AT LYONS, FRANCE.

Last spring the Société Lyonnaise des Forces Motrices du Rhône opened a competition for the best scheme of the utilization of the water power of the River Rhône (20,000 horse power) on the Canal du Touage, to supply the town of Lyons with the electric light and electrical power for industrial purposes. The jury, consisting of Professor Galileo Ferraris, of Turin, Eric Gerard, and R. V. Picou, accorded the first prize to the scheme submitted conjointly by the Compagnie de l'Industrie Electrique, of Geneva and Paris, for the electrical part; and Messrs. Escher, Wyss & Co., of Zurich, for the hydraulic part. It will be remembered that both these firms obtained prizes for their scheme of the utilization of Niagara Falls.

SOME APPLICATIONS OF STORAGE BATTERIES.

R. Macrae

The present activity in storage battery industries and the rate at which these cells are taking the place of primary batteries for the operation of telegraph, telephone, police, fire, burglar alarm and similar systems, not to mention their application to central station lighting and power plants, is particularly gratifying to those who have never doubted that the invention of lead batteries marked one of the most important epochs in the history of the practical application of electricity. The fact that even the poorest type of lead battery that has been on the market in this country was capable, if properly installed, of giving better service for the class of work above mentioned than the best type of primary battery, is sufficient to show that the unfavorable opinion until recently held by the public regarding storage batteries was due not so much to defects in the batteries themselves as to mistakes made in the manner of applying them In addition to the decided improvements that have recently been made both in the construction of lead batteries and in the process of manufacturing them, it has also been recognized that fully as much depends on knowing how to make use of these batteries as on having a good type to begin with. This applies more particularly to the manner of installing the battery and the selection of a battery adapted to the character of the work to which it is applied. Once properly installed, the directions for taking care of a battery are so simple and the attention necessary is so little, that it is almost impossible to fail in getting satisfactory results.



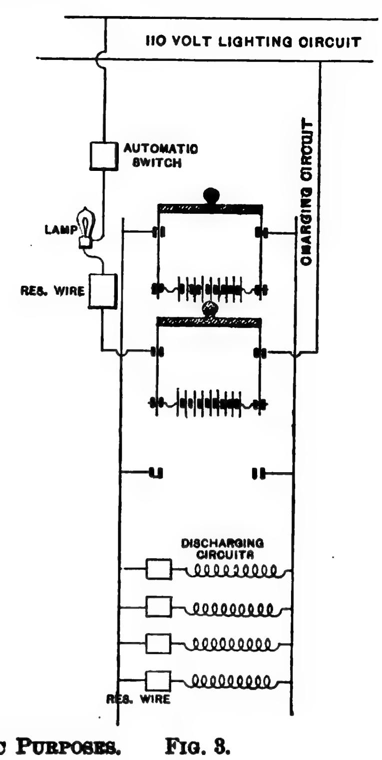


Fig. 1. Applications of Storage Batteries to Telegraphic Purposes. Fig. 3.

When a storage battery is to be used in light and power central and sub stations, for the purpose of removing from the generator curve the peaks and irregularities that exist in the load curve in order to reduce it to the form that ensures the most economical operation of the plant, a careful study of all the conditions peculiar to each individual case is necessary before it is possible to decide upon the battery equipment.

When, on the other hand, the battery is intended for work formerly done by primary cells and for similar applications, a little practical experience is all that is

needed in order to be able to determine at once the character of the outfit required. As, however, even in work of this class, considerable variety exists in the methods of using storage batteries, owing to different local conditions, a description of a few plants of this kind will be of interest to those who are about to adopt storage batteries for similar work.

The first example we wish to refer to is that of the Baltimore office of the Chesapeake & Potomac Telephone Co. The outfit here used consists of two portable four-volt batteries. When one battery is exhausted the other is put on the circuit and the first is carried by two men a distance of about three squares to a charging station. This system has been in use for over two years, doing the work formerly done by about 80 gravity cells and in a manner that has proved in every respect more satisfactory than the service obtained from the primary battery. With regard to this method of using storage batteries the only point we wish to draw attention to is, that on account of the inconvenient arrangement for charging the battery and the fact that a duplicate set had to be provided, put up in a comparatively expensive portable form, the conditions would have been favorable to a continuance of the use of the primary battery if any comparison of the relative merits of primary and storage batteries for this class of work were admissible.

In Fig 1. is shown a diagram of the arrangement

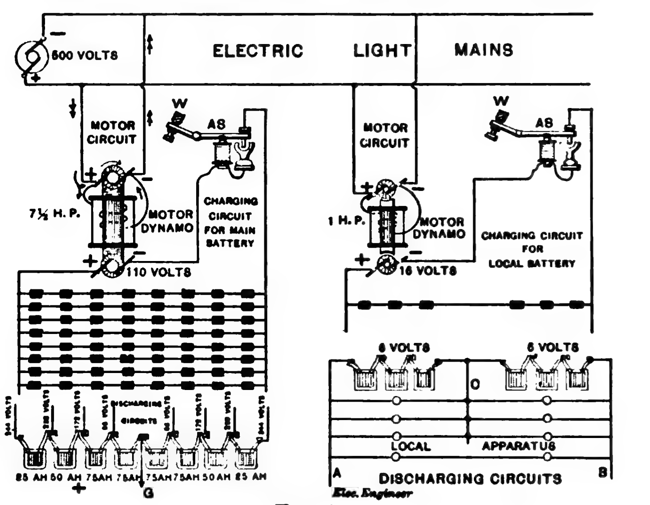

Fig. 2.

adopted for using storage batteries in the office of the Postal Telegraph Cable Co. at Baltimore, and in Fig. 2 is shown that in use in the Western Union office at Atlanta, Georgia. In the Baltimore office the storage battery takes the place of 4,000 gravity cells, while in the Atlanta office 8,000 cells are displaced. As the character of the work done and the local conditions are similar in both cases, while the methods of using the storage battery are different, a comparison of the arrangements used in the two plants may prove of some interest.

In both cases overhead lighting circuits are depended upon for power, and both make use of motor generators for the purpose of converting the current in the street mains to a voltage suitable for charging the batteries. Both also use a high and a low voltage generator. In other respects the arrangements are different. In the Western Union plant a complete duplicate set of batteries is provided, one to operate the lines while the other is charging, with suitable switches for changing the circuits alternately from one set of batteries to the other. In the Postal plant no duplicate parts are provided, and the battery is charged and used at the same time. In both cases it will be noticed that the voltage of the "high" voltage generator is not sufficient to charge the "long ends" of the "Quadruplex" battery in one series. In the Western Union plant, the "long" batteries are divided into sections, which are connected in parallel series while charging and are thrown back into direct series when discharging. In the Postal plant, the "long" batteries are charged in sections, as shown in the diagram. The increase of voltage in the battery that takes place when a section is getting charged is not sufficient to be noticed in the operation of the Morse instruments.

It will be observed that the types of motor generators used in the two offices are somewhat different.

In the Atlanta plant the motor and generator windings are superposed on the same armature and both are excited by the same field magnets. In the Baltimore plant the motor and the generators are separate machines, having their armature shafts joined together in the same line by means of insulated couplings. The former types of machines were at first for a time used in the Baltimore office but they had to be abandoned on account of the liability to damage from lightning, the electricity making its way to earth through the ground on the battery circuit by way of the double winding on the armature. When the batteries are disconnected from the telegraph lines while being charged, as is the case in the Atlanta plant, the liability to damage from this cause is not nearly so great, but in case trouble does not occur the repairs needed are generally more difficult to make on account of the more complicated construction of that type of machine.

Whether the feeling of greater security afforded by the use of the duplicate set of batteries is sufficient to offset the greater first cost and somewhat greater attention required, will probably remain a matter of opinion. That the risk of breakdown due to failure of the storage battery is so small as to seem scarcely worthy of being taken into consideration, can be judged from the fact that during the first summer that the Baltimore plant was in operation, and previous to making the change in the type of generator used, although an armature was burnt out by lightning on an average of about once in every two weeks, and on one occasion the lighting station supplying the power was completely destroyed by fire, not to mention many stoppages due to neglected bearings and brushes, and the fact that no current could be had on Sundays, there was not a moment's interruption of the battery current nor occasion to use the primary battery that was held ready to be switched on in case of an emergency. This fact we think goes far to prove that the storage battery is the most reliable part of the whole system.

With regard to the amount of attention required for a plant of this kind, it may be stated that in the Baltimore office not one cell or connection has been disturbed since the battery was first set up about two years and a half ago. Water has to be added occasionally to make up for the evaporation of the electrolyte. In cells now put up, evaporation is reduced to a minimum by covering the surface of the liquid by some solid substance, such as paraffine, poured on while hot. When first put in operation a daily record was kept of the state of charge of the battery as indicated by observations of the hydrometer and voltmeter readings of each section. The uniformity of the readings, however, rendered this operation monotonous, and it was soon abandoned as unnecessary. The color of the plates is now relied upon to indicate when a section needs charging, while the appearance of the electrolyte shows when the cells are fully charged.

Although both ends of a quadruplex battery are seldom used to the same extent, one or the other or both ends being used according to the amount of business, or the convenience of the operator, no inconvenience is experienced on this account. The charging current is usually turned on to a different section each morning and left on until it is fully charged. Previous to the introduction of the storage battery, it was often found necessary in bad

weather to throw out of operation "one side" of the quadruplex, owing to leakage of current on the lines. Since the storage battery has been in use there has been no trouble of this kind, the battery responding readily to the greater demand made upon it in wet weather without perceptible diminution of voltage.

The battery used in the Atlanta office is of the Chloride accumulator type, and that used in Baltimore is the Donaldson-Macrae type of pasted plate.

In Fig. 3 is shown a diagram of the storage battery outfit used in the City Hall, Philadelphia, to operate police telegraph circuits. A duplicate set of batteries is provided, one to be used while the other is being charged. The charging is done direct from a 110-volt lighting circuit with incandescent lamps for resistance to reduce the voltage.

This arrangement is the one generally used and best adapted for police, burglar and fire alarm systems. On account of the grounds generally existing on these circuits it is necessary to have a duplicate set of batteries in order to be able to charge direct from lighting or railway circuits by simply introducing resistance to cut down the voltage to the desired amount. The loss of current in such resistance is seldom sufficient to justify the use of a motor-generator.

In view of the present state of the art it is somewhat amusing to recall the prejudice that until very recently existed against storage batteries. Three years ago one of the companies making storage batteries designed a type of cell especially intended for telegraph work. After testing it in the factory, a man was sent out with a sample cell to solicit an opportunity of testing some of them on telegraph circuits. The superintendent of telegraphs of a railroad, the first person called upon, was asked if he would take a look at the battery, but before the wrapping paper could be removed from the sample, the superintendent had vanished into his private office. The local manager of the Western Union was next seen, but he thought "life too short to fool with storage batteries." Such was the general character of the reception met with. The representative of a storage battery company does not now, however, meet with nearly so many persons who "know all about storage batteries"; and although some are still found who doubt whether storage batteries are as well adapted as primary cells for the class of work above described, they can hardly be dignified by the name of skeptics. They are simply not informed, and can be relied upon to bring their ideas up to date when they find time to investigate.

As to whether in the very few cases where absolutely reliable power can be obtained all the year round dynamos may not prove as satisfactory as storage batteries for the operation of Morse instruments, there may be some grounds for doubt. An operator familiar with dynamos might not perhaps wish to change to storage batteries, while one accustomed to using storage batteries would certainly not wish to undertake the care of 20 or 30 dynamos. Although, as far as the operation of Morse instruments is concerned, the pulsating current from a dynamo does as well as the current from a battery except for a somewhat greater sparking at the contact points, the induction from such currents very seriously interferes with the operation of telephone circuits in the same neighborhood. This consideration alone ought to be sufficient to render a decision in favor of the use of storage batteries. With regard to the relative economy of the two systems this also appears to be in favor of storage batteries. If, as is now almost universally admitted, a saving can be effected by the use of storage batteries in central stations, running 24 hours in the day, and using large dynamos to furnish current of one or two voltages, it is certainly reasonable to conclude that a relatively much greater saving would result from the use of a storage system where the character of the work is such that it can only be done by a large number of small dynamos of different voltages.

LITERATURE.

Jahrbuch der Elektrochemie (Annual of Electrochemistry), 1894. Scientific Part by Dr. W. Nernst; Technical Part by Dr. W. Borchers. First Year. Halle, a. S., 1895. Wilhelm Knapp. 274 pp., 6½ x 9½ inches. Paper. Price, $2.50.

THOSE who have followed the rapid rise to industrial importance of electro-chemistry will hail with delight a work which proposes to give us, year by year, the gist of what has been accomplished by workers in the field of electro-chemistry. Outside of the electrotyping and plating, electro-chemical operations have had but a small place in the larger industries of nations, and it is only within comparatively recent time that they have begun to occupy an important position in refining of metals. Gradually, however, electro-chemistry is forcing itself into a position of the first rank, and refined electrolytic copper is now a powerful rival, even to the purest Lake copper. But it is not alone in the refining of metals that the newer electro-chemistry will find its application. The production of bleaching and disinfecting materials, already begun, is destined to reach proportions which are now scarcely dreamed of. It has already been demonstrated that bleach and alkali can be produced commercially at a far lower cost by electrolytic means, than by the usual purely chemical process, and the work begun in this direction has but hardly started.

In the work before us the authors, well known authorities in their chosen fields, have divided the subject under two general heads, namely, scientific, and applied electro-chemistry. In the former department, undertaken by Dr. Nernst, we find grouped together the various investigations which have been carried on during the year, including electrolytic dissociation, potential difference between solutions, and the potential difference between metals and solutions, as well as anomalous differences of potentials. Considerable attention is also devoted to electrolytic conductivity, the electrostatic field of the ions, and similar phenomena, and this part of the work is concluded with a description of electro-chemical measuring instruments, including chemical electric meters, among which we notice those of Waterhouse, Oettel, Anders and Kottgen.

The part devoted to applied electro-chemistry shows at a glance the wide field for operations inviting the experimenter, opening with a chapter on the latest forms of galvanic batteries, all of which are briefly but clearly described. The author then passes to accumulators, of the lead and the copper-zinc type, which are treated in a similar manner. Quite properly the author has included in this work a description of the latest methods of reducing metals by the heat of the electric current, applied in various ways, both by the arc direct and by the heat produced indirectly by electricity. It is true that not all the apparatus described has gone into commercial operation, but as the design is to give a record of all that has been done it deserves a place in the volume.

Of special interest is the chapter devoted to the description of the latest work in the obtaining of alkali and chlorine. We here find described a variety of apparatus, including the methods of Oettel, Haeusermann, Naschold, Hargreaves, Berg and Roberts. We also find several forms of apparatus in which the destruction of the electrode is sought to be overcome by the employment of liquid metals, and also apparatus without diaphragms, and a variety of information on organic and inorganic combinations carried out electrolytically. The work is brought to a close with a list of books and other publications on the subject issued during the year 1894, and an excellent index of authors and of subjects. We can heartily recommend this annual to those interested in this growing subject.

Elektrotechnisches Wörterbuch. (Electro-technical Dictionary.) English, French, German. By J. Sack, with addenda by A. Wilke. Leipsic, 1895. Oskar Leiner. 123 pp.; 5½ x 8½ inches. Paper. Price, $1.50.

FOREIGN terms and expressions are so frequently encountered nowadays in technical writings that a handy dictionary has become an indispensable vade mecum to the reader not thoroughly conversant with foreign languages. The ordinary technical translating dictionaries are lamentably deficient in electrical terms, and hence a special work devoted to this purpose will be most welcome. The one before us is very carefully got up, and a critical examination shows it to be singularly free from errors. The work is arranged in three parts, translating as follows: English to German; French to German; and German to English and French. By this arrangement the terms can be readily looked up by a reader conversant with any one of these three languages.

It is curious to note how rapidly the language of electricity is increasing. The author in his preface states that he believes the annual increase of expressions to amount to several dozen words, which emanate largely from English, and more particularly American electrical engineers, who, according to the author, coin them on the slightest provocation. Thus he cites the American term "booster" which he does not consider a legitimate expres-

sion, and hence has omitted from the dictionary, at least for the present. We also note as a curious fact that the French have recently adopted the word *trólet* for trolley and the author also suggests the adoption of the word *Trolle* in German to designate the same object.

TELEPHONY.

THE DELANY SYSTEM OF MACHINE TELEGRAPHY.

MR. P. B. DELANY'S ARGUMENTS AND CLAIMS.

According to official reports there are about a million miles of wire in this country used for carrying messages by telegraph and telephone.

The capital stock of the Western Union and Postal Telegraph Companies and the American Bell Telephone Company aggregates nearly two hundred million dollars.

A new Telephone Company just starting is reported to have a capital of three hundred and sixty millions. Ignoring hundreds of local companies lately sprung up, there is now, or soon will be, over five hundred million dollars stock represented in means of electrical communication.

The number of telegrams sent in the U. S. in a year is now about seventy-five million or about one and one-quarter for each inhabitant. The average tolls are 30 cents and the average cost 28 cents. The number of telephone messages sent is not known. About two million words of press reports are sent daily.

Hardly any one realizes how rapidly the telegraph and post office business has increased in this country. There are seven times as many telegrams sent now as there were twenty years ago.

There were nearly four and one-quarter billion letters sent through the mails last year or about 70 per capita. The total expense of the work was about seventy-five million dollars.

The present receipts of the New York Post Office alone are considerably greater than the receipts from the entire country forty years ago.

During the past ten years there has been an increase in the number of pieces of mail handled of 148 per cent.

Twenty years ago there was no telephone.

Means of communication have progressed from the post-boy, the packet-boat, and stage coach to the fast mail train going forty miles an hour, and the instantaneous telegraph and telephone.

Rapid telegraphy by machinery will carry the bulk of correspondence in the near future. The train service is entirely too slow, cumbersome, and expensive.

Why should a letter of say fifty words be handled by a dozen or more people, sorted, pigeon-holed, bagged and distributed, hauled in wagons and carried in bulk by train from New York to Chicago, occupying over twenty-five hours' time, when it can be punched on a strip of paper in two minutes, transmitted mechanically by telegraph in three seconds, type written in Chicago and dropped in the post office in three minutes more, or a total time of about five minutes, compared with twenty-five hours by train.

This can be done at an actual cost of five cents, but it can only be done by a system having these features, viz., copper wires of high conductivity, machine transmission, and electro-chemical reception.

It cannot be done by present telegraph systems or by telephone, the limit of which latter is about 40 words per minute including repetitions and delays, and as almost every one knows, no reliable record can be made of the message even at this slow speed.

Between New York and Philadelphia a single wire of 800 lbs. copper to the mile worked by the Delany System will carry three thousand words per minute, making a record as perfect as engraving and as plain as print and which can be type written much faster than from stenographic notes, and as it is impossible with this system to mistake a dot for a dash, or couple them together erroneously, there is no chance whatever for mistakes in translation.

To do this same amount of transmission, three thousand words per minute by the present hand system, would require 38 wires worked quadruplex or 152 circuits, at nearly 20 words per minute each, which every telegrapher must admit is too high an average for quadruplex circuits.

Special attention is invited to these two last paragraphs and contradiction is challenged from any telegraphic authority.

Hon. John Wanamaker, through his investigation of systems of telegraphy at home and abroad while Post-Master General, was made aware of the possibilities of machine telegraphy, although at that time the Delany automatic system was not perfected. In his report for the fiscal year ending June 30, 1891, he says:

"Since the introduction of the quadruplex twenty years ago, the Western Union Company has, I am told, made but one change or improvement in it's method of telegraphic transmission having for their object the greater speed or the transmission of a larger volume of traffic of a given wire. I refer to the Wheatstone Automatic, an English invention, which has been in successful use on the Government lines in that country for eight or ten years. On the other hand, England has not only adopted our quadruplex, but also the Delany Multiplex, another American invention.

* * * * * *

The Western Union Company, having control of the telegraph business, has no use for devices which cheapen and quicken the telegraph service and warrant a claim for reduction of rates. The public, not knowing what it misses, cannot become aroused to the defects in methods now in vogue."

* * * * * *

That Post-Master General Wanamaker appreciated the benefits which would inure to the entire people from low rates and that he foresees that the bulk of correspondence will be telegraphed, the following extracts from his report fully show:

"The rapid transmission of correspondence is a part of the business and proper duty of the Post-Office Department, and it does not fulfill its functions or perform its full duty until it operates the telegraph, the most rapid means of transmission of intelligence."

* * * * * *

"The one potent agency and the only one that remains beyond our reach is electricity. Its practical value has been known for half a century, but the Department stands in relation to it where it stood 50 years ago. The business of the entire world is to-day so dependent upon electricity that its withdrawal would seriously affect almost every interest that exists; yet the chief servant of all the people, the post-office, which by its equipment is able to make the largest and most beneficient use of it, is so limited in its authority that it can only adopt the slower methods."

* * * * * *

"I believe more earnestly than ever that the telegraph ought to be applied to the postal service so that the two great systems, like the railroad and postal service, may quicken and cheapen transmission of messages for the benefit of the unserved many."

* * * * * *

Telegraph Companies have argued against telegraphy by the government on these grounds:

First, that messages were already being transmitted as cheaply as or cheaper than the government could transmit them.

Second, that any interference by the government would be a great hardship to the telegraph owners, and an impairment of their vested rights, etc.

Of course every one at all close to the question knows very well that the telegraph companies are by interest bound to make an ostensible fight against government telegraphy, so that when it comes about they will be in a position to demand a large sum for their property. If they favored purchase by the government they could not pose as martyrs to the public weal. The telegraph interests are arranging matters for the future.

The history of the telegraph in this country is unique. So long as a portion of the traffic could be diverted to a new company, opposition lines were built, and as fast as new lines were built the Western Union Company felt compelled to buy them up, in order to prevent competition. Thus, about forty opposition lines of very inferior construction have been taken over, and have swelled the Western Union mileage to an abnormal degree.

By this policy the company became a possessor of wires, not a promoter of systems. So long as they had wires thrust upon them, sometimes in advance of the business requirements, they did not care to render them valueless by development of fast telegraphy. This policy of discouragement of all improvements of systems has cost the Western Union Company a great deal. They might have bought Bell's Telephone for a paltry sum twenty years ago. Five per cent. of its subsequent value would have paid for all the improvements in telegraphy ever offered to them. To-day the telephone is as great as the telegraph.

Without desiring to disparage the efforts of others that have made progressive steps in this branch of electrical science, it is necessary in pointing out the advantages claimed for the Delany system, to state some of the defects which have beset all the others, which defects will be acknowledged by all electricians and telegraphers competent to speak on the subject. These defects have been:

First. The Perforating Machine.—From Bain's crude and impracticable instrument through the gradual improvements by Siemens, Humaston, Phelps, Little, Edison, and others up to the very ingenious, but complicated perforator of Anderson, the preparation of messages for automatic transmission has been attended with much difficulty. Perforating machines have been complicated, easy of disarrangement, difficult to operate, and very expensive, some of them costing as high as $800 to make.

The Delany perforator has but three keys, and three moving parts. It cannot get out of order. It may be worked after a few days' practice, and it costs but $75. It can be worked at the rate of 25 words per minute.

Second. The Transmitter.—Heretofore all transmitting machines for fast automatic telegraphy have employed a contact finger, brush or wheel, pressing on top of the perforated strip and making electrical contact through the perforations with a revolving wheel underneath the tape. This form of transmitter has always been unreliable in operation, mainly on account of the face of the wheel becoming gummed with dust and oil from the tape, thus causing imperfect contact, which difficulty was aggravated by the lubricated connection rendered necessary by the revolving wheel.

In the Delany transmitter these defects are wholly obviated. The contacts are made by wire contact brushes *above and below*

the tape, pressing toward each other. When the paper intervenes the circuit is broken. When a perforation is drawn between the brushes of course the circuit is instantly and perfectly completed. The brushes are made up of six wires each, so that there are really six contacting points, which insures unfailing and uniform transmission. There are no revolving wheels, and the brushes are constantly cleaned by the edges of the paper between the perforations. A year's experimentation and actual working over long cables, requiring absolutely perfect contacts, has not developed a single failure with this form of transmitter. There is no loss of motion or time in making the contacts as is the case with all other automatic transmitters. The brushes are never separated more than the thickness of the tape, and the time consumed in coming together at each perforation is practically inappreciable.

Third.—Heretofore in automatic chemical telegraphy dots and *dashes* have been punched in the transmitting tape and sent over the line.

The line is more heavily charged by a dash than by a dot. It is well-known to electricians that when a line is charged for unequal periods the static *discharge* following each unequal signal is also unequal, that is to say: When a dash is sent there is a greater current discharge from it than when a dot is sent. Consequently, with high speeds on lines of any considerable length, the discharge following a dash is almost sufficient to obliterate a dot following immediately afterwards.

In the Delany system *no dashes are sent.* Nothing but dots, but owing to the currents employed, and to *a new form* of receiver, such of these dots as are meant for dashes are plainly designated as such on the receiving tape.

On the punched tape all dots representing dots are in one plane, and are sent from one pole of the transmitting battery, while all the dots representing dashes are in another plane and are sent from the opposite pole of the battery.

At the receiving end of the line all the dots are similarly in one (the centre) plane, while the dots representing dashes are *divided* and formed in *two* lines, one above, the other below the dot line, so that it is impossible to mistake a dot for a dash.

In this way the well-known effects of "tailing" or running together of signals is avoided on the receiving tape.

This important feature of the Delany system not only permits great increase of speed but renders translation of the characters by the copyist or typewriter much easier and more certain.

Over an ordinary iron wire, 350 pounds to the mile between New York and Philadelphia, which now yields 60 words per minute quadruplexed, it will carry 2,000 words per minute.

With a copper wire weighing 300 pounds per mile between the same cities, it will carry 3,000 words per minute.

It will carry 1,000 words per minute between New York and Chicago over a copper wire weighing 350 pounds to the mile.

The cost of a line of two copper wires, 350 pounds per mile each, constructed on poles in the best manner, everything included except rights of way, would be about $550 per mile, or

for 1,000 miles	$550,000	
Cost of apparatus, etc., at both cities, all ready for working	$ 25,000	
		$575,000

Operating Expenses.

Rents, light, fuel, per year	$30.000	
Labor 150 employees	90,000	
Superintendence	10,000	
Perforating and receiving tape	30,000	
Repairs, patrol, etc	20,000	
Battery, stationery, etc	10,000	
Postage for delivery at 2 cts. per message	57,600	
	$247,600	
Interest at 6 per cent	34,500	
		$282,100

Earning Capacity.

Two wires operated at an average speed of 500 words per minute each, including all delays.

Total words per day, 1,440,000; 50 words per message, 28,800 messages per day; at 15 cents each, $4,320 per day.

Total per year, 300 days	$1,296,000
Operating expenses	282,100
Balance	$1,014,000

It may be asked whether this large volume of correspondence could be secured. There can be but little doubt about it, as there are upwards of 40,000 letters carried between New York and Chicago daily, several thousand telegrams at the present rate of 40 cents for ten words, a large amount of telephone conversation at over a dollar a minute, and an immense amount of newspaper work.

There are probably several thousand special delivery letters exchanged between these two cities daily, costing ten cents extra postage to expedite their delivery *half an hour* after about 24 hours have been consumed in train transportation. It is but fair to assume that nearly all these latter would be telegraphed by the Delany system.

General Plan.

The general plan for a company to make an entirely new departure in telegraphy should, it is thought, be about as follows:

It should not compete for stock or exchange business requiring instantaneous transmission and delivery, but should seek the less urgent business of greater volume, and at rates which would secure at once a large share, and eventually the greater portion of the correspondence now conducted through the mails.

Instead of maintaining hundreds of branch offices involving great outlay, there should be but one central station, located close to the General Post Office in each city. Messages could be sent to these central stations from any part of the cities, or from points adjacent, through the mails, in the ordinary way. Each sender of a message would enclose the requisite tolls in stamps issued by the Company, and which would be on sale at drug stores and other places throughout the city. A uniform tariff, 50 words for 15 cents, and one cent for each additional five words, or fraction thereof, would be charged. A message placed in an envelope directed to the central office of the company and dropped in any post box within the city limits, would reach the telegraph office, on an average, within an hour. It would be transmitted and dropped in the General Post Office at the other end within ten minutes, and would be delivered by the postman within an hour thereafter.

Thus, letters would be collected, transmitted and delivered, on an average, within two hours, for 15 cents, as against about 30 hours at a cost of 2 cents, or 12 cents if an extra 10 cent stamp is used.

At present to send a letter from New York to Chicago and get a reply takes 3 days. Surely a large percentage of these letters would be telegraphed if a reply was certain to be in hand within three or four hours.

As the single telegraph station would be located in the centre of the business district in each city, special delivery by the Company's messengers could be made for 5 cents extra charge, thus reducing the time for a telegraph letter and reply to about an hour, which is much quicker than the average time necessary for the ordinary services at present.

In addition to the traffic originating in Chicago and New York and intended for delivery within the city limits, it is but reasonable to suppose that letters for towns and cities adjacent, or even far beyond would be sent by telegraph over the 1,000 miles intervening between the two distributing points. Letters from New York for Milwaukee, St. Louis, St. Paul, Minneapolis, Denver, San Francisco and other places could be mailed at Chicago, thus saving about 24 hours. And in like manner letters from Chicago for Philadelphia, Baltimore, Washington, Boston and other points in the east could be mailed from New York.

As a matter of course a system of this kind employing a minimum number of wires with maximum carrying capacity could be extended to all the large cities of the country, practically carrying the mails and securing a great portion of the patronage now enjoyed by the telegraph companies.

An outlay of say ten millions in lines operated by this system in the manner proposed would afford facilities for carrying as much traffic as is now handled by all the companies combined, with capital stock approximating 150 millions.

Should government telegraphy ever come about it must be by this or some other system equally as rapid, for by no other means could so great a volume of business be handled at low rates.

Telegraph properties as now constituted consist of poles loaded down with cheap wires, and operated manually, by systems necessarily slow. To provide facilities wires have been multiplied until the poles are overloaded. This aggregation of wires on each line of poles has seriously impaired the usefulness of each individual wire. That is to say, if five new wires be strung upon a line of poles previously carrying five, it must not be supposed that the telegraph company has doubled its capacity. The added strain on the poles, increased liability to interruption of a number of wires by the breaking of one, together with the various electrical complications introduced, impairs the efficiency of the entire ten to an extent which would be fairly represented by seven perfect working wires.

The telegraph of the future will comprise substantial poles, a few large copper wires, and rapid automatic systems capable of utilizing the full carrying value of the conductor.

It is estimated that it costs $4 per mile per wire per year, to keep the present lines in repair. A copper conductor costs no more to maintain than an iron one. On this basis two copper wires operated by the machine system with a capacity equal to 40 wires operated by hand, as at present, would cost $8,000 per year to maintain between New York and Chicago, as against $160,000 per year for the maintenance of the 40 hand worked wires.

In conclusion, the automatic system has the great advantage of secrecy; if desired, messages may be perforated by a clerk or private secretary or typewriter, and sent to the telegraph office where the tape is run through the transmitter. The tape may then be taken away by the sender of the message. At the receiv-

ing end the tape containing the message is delivered direct to the person for whom it is intended, for private translation. The telegraph clerk simply reads the name and address and encloses the tape in an envelope. In this way also the cost of correspondence to business firms and others preparing and translating their own messages would be greatly reduced.

THE TELEPHONE IN ENGLAND.[1]

BY G. L. ADDENBROOKE.

During the course of the writer's preparations for the review of Mr. Bennett's work on the telephone systems of the Continent which appeared a short time since in this journal,[2] some points were brought into prominence which did not appear to come within its scope, but which nevertheless appeared of importance. These were accordingly reserved, and a portion of them are now published, as they form an apt and fitting comment on the chairman's speech at the recent general meeting of the National Telephone Company.

Scattered through Mr. Bennett's book are the rates of wages paid in each country. It occurred to the writer to extract these in the form of a table. To these he has added the rates which are paid by the Telephone Company and Post Office in England. Mr. Bennett has himself kindly checked the table to see if it was a really fair statement to deduce from his figures. The English figures have also been seen by Mr. Preece at the Post Office, who expressed his general concurrence with them. That they represent fairly the National Company's wages the writer has also reason to know. It has been a little difficult to make a fair comparison because of dietary and other allowances given on the Continent and not in this country, but if anything, the comparison is in favor of England.

The table has been got out in the form of shillings per week, neglecting fractions to admit of ready comparison.

TABLE SHOWING WAGES PAID PER WEEK IN SHILLINGS.

Country.	Outdoor Operatives. Foremen.	Wiremen.	Laborers.	Switch-room Operatives.
Austria	28	20	15	8 to 10, to 14 in 3 years.
Belgium	32 to 40	14	11	8 to 16
Denmark	40	26	21	5.5, 4 hours, to 14.5, 6 hours.
Bavaria (Germany)	40	23	17	12, boys.
France, Paris	40*	30	..	12 to 20
France, Provinces	36	24	..	10 to 18
Holland	30 to 40	24	18	6 6 to 10
Norway & Sweden	27	20	15	11 to 19
Switzerland	30 to 36	22	15	15 when fully competent.
England, London	38 to 45	28 to 34	21	About 10 average.
England, Provinces	27 to 42	23 to 26	20 to 23	About 9 average.

* And allowance.

Besides its bearing on the telephone industry this table has a wider interest, because the wages in telephony approximate in all cases to the wages paid for line work in telegraphy in all the countries, and these wages again are about the same to those paid in the allied electrical industries. These wages are therefore some indication to electrical engineers of the relative scales current in the chief countries on the Continent. It is only fair to remark also that the writer has good reason to believe that, with the exception perhaps of Paris, house rent is cheaper all over the Continent than in England, and the price of commodities generally rather less. The foreign workman is, therefore, generally in rather a better position relatively to his English *confrère* than the figures show, while on the other hand there is, it is well known, a general idea that an Englishman gets over the ground rather quicker. When these matters are taken into account, it will be seen how closely the reward of labor, in this industry at any rate, approximates in this country. Belgium seems to form the most remarkable deviation.

Returning to telephony, the remarkable points about this table are that foreign wages for outdoor work approximate in many cases closely to English; while for switch-room operatives, who are mostly ladies, the wages paid abroad are, if anything, higher than our English rates. It is clear, therefore, that there is no argument from these items that English exchange subscription rates should be more than a slight percentage above foreign; since the labor in erecting lines is nearly as much abroad as in England, while the cost of operating—the real criterion, as it is a continual charge—is even less in England than on the Continent.

As regards the price of instruments and telephone material, they are pretty much the same everywhere, and, if anything, the advantage should lie with England.

1. *London Electrician.*
2. See also review in THE ELECTRICAL ENGINEER, July 17, 1895. (Vol. xx, No. 376, p. 56.)

The rates of annual subscription on the Continent and in England are as follows, the amounts being taken to the nearest shilling to make the table clearer and afford a readier means of comparison :—

——	Annual subscription.	Capital payment (if any).	Distance.
	Shillings.	£ s. d.	
Austria	83	4 3 4	500 metres (extra for extension)
Belgium—Antwerp	200	....	3 kilometres.
Brussels	200	....	
General State rate, (double wires)	...	....	....
Denmark—Copenhagen	166	....	....
Provinces	40 to 90	....	....
Germany	151	....	....
Holland—Amsterdam	195	....	....
Dordrecht	84	....	....
Breda	66	.. .	....
Hungary—Buda Pesth	250	....	....
Other towns	100	....	....
France—Paris	330	...	....
Lyons	240	....	....
Co-op. Societies	40	£8 to £10	....
Italy	160 to 56	...	....
Norway—Christiania	90	....	....
Provinces	66 to 28	....	....
Sweden—Companies	111	2 15 7	...
Government	89	2 15 7	....
Switzerland—First Year	96	*	....
Second Year	80		
Third Year	61		
United Kingdom—London	400	...	....
London, Five years	340	....	....
London, Private residents	240	....	....
Principal towns	200	....	¾ mile.
Few small centres	180	....	....

* 800 calls per annum, extra has to be paid on additional calls.

If, then, from what has been said above, a telephone line can be erected nearly as cheaply in England as on the Continent, if the materials for the line and the instruments at the subscribers' end and at the exchange are the same price, and if the line, after it is erected, can be operated quite as cheaply in England as on the Continent, it is clear that there must be some other reasons why a satisfactory telephone service can be provided at so much cheaper rates in many cases on the Continent than the National Company allege is possible in England.

THE NATIONAL LONG DISTANCE TELEPHONE CO. OF KANSAS.

A number of the business men of Topeka, Kan., who are now interested in the telephone system which is in competition with the Bell Company in that city are perfecting plans whereby a new company will be organized in Topeka with a capital stock of $200,000 to be known as the National Long Distance Telephone Company. The capital stock of the company will be divided among a number of Kansas towns. Those which are just now the most deeply interested are Holton, Horton, Atchison, and the principal towns in that section of the state which have been making an effort to secure telephones. Many of the cities in northern Kansas have recently chartered companies for the construction of telephones but the plans have been changed and now the one big company will be organized, local and long distance lines will be constructed and the cities will secure the benefits of a toll system which it is asserted will be operated much more cheaply than that of the Bell Company as the charge for using the long distance lines will be placed at 25 cents instead of 50 cents.

Simon Greenspan, A. K. Rodgers and other members of the Topeka Telephone and Electrical Company, which has succeeded the Harrison Company in that city, are backing the new enterprise. The plans are now in such a shape that the men who are pushing the matter are confident that the work will be consummated shortly. In fact, one of the members of the new company states that work would begin at once to build the first line to Holton. The line to Holton will be pushed to completion, extended to Horton and other towns along the Rock Island and on through the portion of Kansas, north and east of Topeka until the system has been made complete. Manhattan is figuring on joining the new company and prominent citizens in many of the central Kansas towns are desirous of gaining admission to the new corporation with the intention of competing with the Bell Telephone Company.

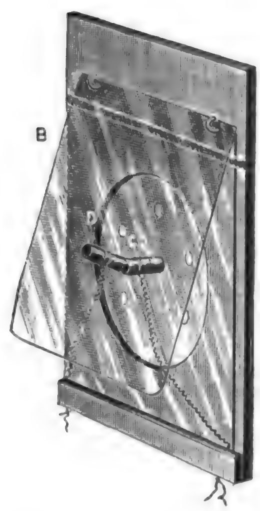
WILMINGTON, N. C., like Winston-Salem, is to have a competing telephone company. The aldermen of that city have just granted the Inter-State a franchise to establish and operate a plant there.

BLUE EARTH CITY, MINN.—The Blue Earth Valley Telephone Company, a recently incorporated company, have been granted a permit by the city council to erect poles in this city, and to provide for a long-distance service as well as local.

THE HOGAN DUPLEX COMPENSATING TELEPHONE.

THE accompanying illustration represents the Hogan "duplex compensating" telephone transmitter, recently brought out by the Hogan National Telephone Co., of Chicago, and which embodies a number of novel features. As will be seen, the instrument consists of a very thin sensitive plate of mica, A, through which a carbon pencil electrode C is fitted. This plate is made so sensitive as to be actuated by the lowest whisper, and is perforated, as shown, so as to allow a small percentage of the force of the sound waves to pass through this plate and strike plate B which is also of mica, in which is fitted a second carbon electrode D which by gravity is made to press against the electrode of the primary plate.

When one speaks in a low tone or whisper, the primary disc is actuated and corresponding undulations are produced in the current. If the instrument is spoken to in a loud tone, then a small percentage of the sound waves pass through the perforations of the primary disc and strike the secondary disc, which actuates that in harmony with the primary, and relieves the transmitter of any abrupt or jarring sound, that would naturally be the consequence of a transmitter adjusted to extreme low tones, without such a compensating plate.



THE HOGAN TELEPHONE.

Thus it is claimed that the instrument is adapted for short line as well as for long distance work, and since gravity alone is employed to keep the electrodes in contact the instrument maintains a constant adjustment.

THE GOVERNMENT TELEPHONE SUIT.

A special dispatch from Washington of August 28 says: The law officers of the Government have under consideration the question how further to proceed with the case against the Bell Telephone Company for the repeal of the Berliner patent. As the case now stands, the bill of the Government has been dismissed by the Court of Appeals for the First Circuit, and under that judgment the Bell Company has begun proceedings against several of the corporations which entered the telephone field after the expiration of the Bell patent, in 1893. The validity of the Berliner patent is essential to the further control of the telephone business by the Bell company, and the present situation is of additional interest, from a legal or judicial point of view, because the case involves a consideration of the act of 1891, establishing circuit courts of appeal.

By the terms of the act creating circuit courts of appeal the judgments of those courts are final in all cases arising under the patent laws, except where the Judges certify a case to the Supreme Court, or where the Supreme Court directs the case to be brought before it for review on a writ of certiorari. The telephone company is evidently inclined to accept the decree of the Court of Appeals as final, and is proceeding to enforce its claims under the patent. But the Government representatives are by no means disposed to let the case rest here. They say that a case involving the question whether or not the United States has the right to sue for cancellation of a patent is vastly different from a controversy between two private parties over a patent right, and that upon that point an appeal will lie to the Supreme Court from the judgment of the Court of Appeals. And even if that ground should fail them, they can sue for a review of the case on a writ of certiorari, as provided in the law itself. Which method of procedure will be followed has not yet been finally settled, but it is asserted that the case will not be permitted to rest in its present condition.

USE OF THE TELEPHONE WIRES FOR NEWS PURPOSES.

The Long Distance Telephone people did an immense business here during the convention hours Wednesday. It was the first time the Long Distance Telephone has figured in a convention in this city, and many newspaper men outside of Cincinnati, Chicago, and Cleveland, depended solely on the Long Distance for doing their work. Every evening paper in the state, who had a representative here telephoned the news of the convention Wednesday in time for publication that evening.

Manager W. A. Vail, of N. Y., was in charge with a corps of attendants consisting of C. A. Hunter, Cincinnati; G. E. Calhoun, Indianapolis; F. A. Pearl, Cincinnati; and C. Brooks and E. L. Cook, Chicago. Three booths were placed in the rear of the stage, and were kept in constant use, and two each in the Arcade and Lagonda house. Major Hoover, of the local exchange, in charge of the Long Distance business here, said that everything worked in perfect order. The lines and connections were in perfect shape, and the company was much pleased with the business done here. Mr. Vail and his assistants left for their respective homes Thursday evening. Extra booths will be left in the Arcade until after the meeting of the editors of Ohio, who come here in a body to call on General Bushnell, on the 27th inst.—*Springfield, O., Republic-Times.*

TELEPHONE NOTES.

PRINCETON, N. J., is establishing a local telephone service.

DEERFIELD, MASS., is soon to have telephone connection.

SULLIGENT, ALA.—A company is being formed to build a telephone line between Sulligent and Vernon.

BEREA, KY.—Rawlings and Fish have formed the Berea, Kingston & Richmond Telephone Co. to construct telephone lines.

FORT WAYNE, IND.—Mr. C. S. Bash has presented a petition for a franchise for the Fort Wayne telephone company.

SAN FRANCISCO, CAL.—The People's Mutual Telephone Company will be ready for business July 1, 1896.

PERRINTON, MICH.—The Maple Rapids Telephone Co. is building a line from Perrinton to Ithaca by way of Pompeii.

GRENADA, MISS.—B. L. Roberts, Emile Levy and H. W. Latimer have incorporated the Grenada Telephone & Telegraph Co. to construct lines. The capital stock is $250,000.

SAN JOSE, CAL.—The City Council has granted a franchise to the California Telephone and Construction Company. The franchise was sold for $50, and is to run for twenty-five years.

MELROSE, MASS.—At a special meeting of the selectmen permission was granted the Century Telephone Company to erect seven poles within the limits of the town.

GARRISON, COL.—The telephone line which has been under construction between here and Duncan for several months now is about completed.

TOLEDO, O.—The Central Telephone company have completed arrangements to build a $75,000 building. The site has not yet been made known.

PORT HURON, MICH.—An effort is being made by the local management to sell the Harrison Telephone plant to local capitalists.

LEADVILLE, COL.—The Colorado Telephone company is building a line from Leadville to Aspen over Independence pass, as rapidly as the task can be accomplished.

TOPEKA, KAS.—The McPherson Telephone company has been incorporated. The capital stock is $5,000 and the directors are as follows: J. E. Wright, J. R. Wright, J. G. Maxwell, L. M. Waitt and H. G. Smith.

WINONA, MINN.—Winona and Eau Claire, Wis., are soon to have telephonic connection, and as Eau Claire and Philips are already connected, service will be had between Winona, Philips and all the intervening towns. A line is also soon to be built between Winona and Arcadia, Wis.

NEWARK, N. J.—The Newark Telephone Company has filed articles of incorporation in the County Clerk's office. The company will do a general telephonic business in that city, Essex County, and Hudson County. It has a capital stock of $800,000, and there is $100,000 to begin active business.

HALIFAX, N. S.—A despatch from Charlottetown states that E. Franklin Clements, of the Standard Telephone Company, of New York, is at present trying to obtain consent of the Prince Edward Island Government to construct a trans-continental telephone system in that province. It is intended landing the cable at Cape Traverse. Clements is also arranging for the establishment of an electric street railway in the city of Charlottetown, to be built by American capital.

WAYCROSS, N. Y., is to have a telephone exchange.

OTTAWA, ILL.—The Bell Telephone Company has secured a controlling interest in the Dundas Telephone Company.

WAUSAU, WIS.—The Wausau Telephone Company expects to be ready for business about October 1.

BONHAM, TEX.—There has been chartered the Texas Telephone Company of Bonham.

ROSCOE, N. Y.—At the meeting of the proposed stockholders of the new telephone line from Roscoe to Lew Beach, the required amount, $1,500, was raised.

HOULTON, ME.—Mr. J. K. Butler, Supt. of the Eastern Division of the White Mountain Telephone Co. is arranging for a new telephone line between Houlton and Patten.

RUSSELL, ONT.—The Bell Telephone Company has begun to build the line from here to the main line leading from Ottawa to Montreal.

ALLENSVILLE, TENN.—The Cumberland Telephone and Telegraph Company is now engaged in extending the lines to Allensville and other points beyond Guthrie.

PENDLETON, ORE.—It is now expected that the line of the Blue Mountain Telephone and Telegraph Company will be erected and in full working order to Canyon City by November 1.

SUGAR GROVE, N. Y.—A telephone line connecting this place with Youngsville and intermediate points has lately been completed.

DOLGEVILLE, N. Y.—The Dolgeville Telephone Company will this year extend its line north, connecting with Salisbury, Salisbury Center and Stratford.

LISBON, N. D.—A telephone line is to be built from Fargo to this place connecting with the Fargo and Grand Forks circuit. Forty miles of line west of Tower City is completed.

REDLANDS, CAL.—The new apparatus for the telephone exchange has arrived and will probably be put in immediately, and Redlands will then have an up to date exchange.

CLEBURNE, TEX., will have a city telephone exchange put in by the National Telephone Company. Residences are to be charged $1.50 and business $3 per month.

HATBORO, PA.—William R. Dougherty is pushing the erection of the new Bell Telephone building, on West Chelten avenue, which will cost about $7,500.

DANVILLE, KY.—Mr. Eddy has secured twenty more telephones and expects to have a number of new subscribers supplied at once. He is also preparing to put in a new switch board.

VERNON, ALA.—The construction crew of the Courier Telephone Company, at Vernon, have commenced the erection of a line from Vernon to Fayette.

SAUGATUCK, MICH.—A new telephone company, to be known as the Saugatuck & Ganges Telephone Company, has been organized and will run a line from Saugatuck to Ganges via Douglass.

ALBANY, N. Y.—The board of aldermen, by unanimous vote, has granted a charter to the Home Standard Telephone company. The work of constructing the lines of the company will be commenced without delay.

SPARTA, WIS.—The City Council have voted the right to J. P. Rice and H. M. Sowle to build a telephone line through the streets of Sparta. It is understood that J. P. Rice of this city and H. M. Sowle of Tomah will build a toll line from Sparta to Tomah.

LANSDOWNE, PA.—The citizens of Lansdowne and vicinity are about to start an opposition to the regular company. They propose to put telephones into stores at $2.50 per month each and in private residences for $1.50 per month.

HUNTINGTON, W. VA.—The Huntington Mutual Telephone Company will very soon be in operation. The Old Dominion Electrical Construction Company, which is to put up the wires, has a large force of men at work.

BUENA VISTA, PA.—The Bedford County Telephone Company will extend its line from New Buena Vista to New Baltimore, the Town Council of the latter place having granted a permit for the erection of the necessary poles in the borough limits.

SIOUX CITY, IA.—The war on the Bell Telephone company here has begun in earnest. H. O. Woodruff, manager of the Sioux City Electrical Supply company, is disconnecting telephones of the Bell system wherever he secures permission.

ST. JOSEPH, MO.—Work on the new telephone line here has been stopped. The petition of a majority of the stockholders of the Citizens' Telephone Company for the appointment of a receiver and the issuance of a temporary injunction restraining Louis L. Strong from disposing of the company's bonds has been granted.

ABINGTON, MASS.—The Abington and Rockland Street Railway Company is at work on a new telephone system of its own. The company is building a line in connection with its own system of wires, and little sentry boxes are placed at intervals all along the road to South Weymouth.

MARSHALL, MO.—A new telephone line has just been completed to Slater from this city. It will be continued to Arrow Rock soon. Marshall will then have telephone communication with Fairville, Miami and Malta Bend, and perhaps with Sweet Springs later on.

RED HOOK, N. Y.—The Red Hook Telephone Co. have their line completed to Barrytown and Annandale. A connection will be made at Red Hook with the Hudson River Telephone Company, and at Barrytown with the Western Union Telegraph Company.

CLARKSVILLE, N. Y.—A meeting of the Clarksville and Feura Bush Telephone company has been held here. A large number of new members were added, and it was decided to at once build a line from this place to New Salem and Voorheesville and thence to New Scotland.

MANNINGTON, W. VA.—At a meeting of the board of directors of the Fairmont and Mannington Telephone Company it was decided to begin immediately the construction of a telephone exchange in Mannington. This company is already operating lines to several nearby towns in this county.

OAKLAND, CAL.—A bid for a telephone franchise has been received from the Commercial Telephone Company of Alameda County offering $50 for the franchise and half of one per cent. of the gross receipts. The bid was referred to the Ordinance and Judiciary Committee.

LANSING, MICH.—Jacob Stahl has contracted for $14,000 worth of telephone instruments from the Western Telephone Construction Company, of Chicago. Mr. Stahl, who is treasurer of the new Lansing telephone exchange, expects that the new exchange will be in working order October 1.

ATLANTIC CITY, N. J.—The Telephone Company of South Jersey, which is seeking a franchise here, is the same company which has been given franchises in Camden and also in Cape May. The company wants to erect poles and string wires for telephone, telegraph and burglar alarm systems.

CARBONDALE, PA.—A telephone system has been established here and the title of the Carbondale Telephone company adopted. The officers elected for the purposes of incorporation were: President, A. P. Trautwein; treasurer, Edward Clarkson; secretary, G. P. Rogers.

BUTTE, MONT.—One of the heaviest contracts yet undertaken by the Rocky Mountain Bell Telephone Company has been closed and the construction of an independent telephone line between the Montana cities of Butte and Great Falls will be commenced by the telephone company, and the work pushed to an immediate completion.

INDIANAPOLIS, IND.—The city council has passed a sweeping ordinance repealing all telegraph and telephone franchises within the business district of the city, including territory a mile square, and ordering that all telephone and telegraph wires be removed within a reasonable time. This is a determined stand by the council looking to the placing of all wires underground.

MEMPHIS, TENN.—A contract with the Memphis Telephone Company has been agreed upon. The contract states that the Memphis Telephone Company has agreed with the American Telephone Construction Company for the erection of a plant and exchange in Memphis, using the American telephone and Hunnings dust transmitter.

CHESTER, PA.—An ordinance has been introduced which provides for the establishing of a new telegraph and telephone company to be known as the Chester & Philadelphia Telephone and Telegraph Company, composed of Philadelphia capitalists. The president is Charles A. Furbush; vice-president, Daniel McCormick; secretary and treasurer, John J. McCloskey.

PATERSON, N. J.—Mayor Braun has signed the ordinance giving the New-York and New-Jersey Telephone Company power to lay conduits and subways for its wires in the streets. With $1,000 in taxes, $1,500 in telephone rentals saved by the stipulation of free service for municipal buildings, and at least $500 franchise fee, the city will, it is claimed, gain $3,000 annually by the new arrangement.

SUMNER, IA.—At the annual meeting of the stockholders of the Western Electric Telephone company, held in the company's office, J. F. Cass, Chas. Webster, Stitzel X. Way, Thomas A. Way and T. A. Potter were elected directors for the coming year. J. F. Cass was elected president, Chas. Webster vice-president T. A. Potter secretary, Thos. A. Way treasurer and general manager, J. G. Graham, superintendent and George S. Barr assistant secretary.

LETTERS TO THE EDITOR.

THE EXPRESS vs. THE MULTIPLE TELEPHONE EXCHANGE BOARD.

I have read the description in the ENGINEER of the new Express telephone switch board, and I cannot, for the life of me, see that it is an improvement on the multiple board.

We used, years ago, various forms of connecting tables, on to which we threw the caller, and he was there connected with the desired number. When finished, he was disconnected by a "clearing out drop" signal. For some time, one was used in the Milwaukee Exchange, invented by Harry C. Haskins. That system took two operators to make a connection. It was followed by the multiple board. That uses but one operator.

Brother Sabin's board requires three operators—four glow lamps—four relays—four spring jacks and plugs and a main battery to call with! Whew!! How would all this apparatus work in an exchange of 3,000 subscribers?

Better than this is the old board, where the operator made a ticket, the boy trotted down the board to the desired number, the operator there put the subscriber wanted on the trunk line mentioned in the ticket, and the connection was made. The only uncertain link in this chain, was the uncertainty of the boy, who frequently gave the ticket to the wrong operator and caused delay.

If, as stated, errors occur with the multiple board, where one operator makes the connection, what would be the result with this new system, with such a multiplicity of operators, relays, lamps and plugs?

C. H. HASKINS.

BUFFALO, N. Y., Aug. 24, 1895.

WAS IT AN INVENTION OF THE LIGHTNING REPORTER?

Referring to your article in the issue of Aug. 7, "Can Lightning Run Trolley Cars?", THE ELECTRICAL ENGINEER does not seem to have taken the story seriously but some of your readers evidently have done so.

In preparing a recent article on "Lightning Protection" for the New York Sunday *World* I had occasion to investigate some wondrous lightning displays said to have occurred in Harlem and other places, and what did I find? In one case lightning had knocked a chimney down and dispersed harmlessly upon the tin roof. In another case lightning came through a motor car, and broke up a fuse block. Two or three other cases that I investigated in Brooklyn were similar.

In the first case the lightning reporter described balls of fire as floating around through the flats, circulating round a gas stove, taking out a window, sash and all, and finally hitting the sidewalk and exploding with force enough to break all the windows in the block. In the second case a big ball of lightning came down through a tree, rolled along the tracks as if in doubt whether to take the ground or not until it met the motor car which seemed to excite a violent antagonism and which it punished by tearing a hole six or eight inches square in the controller box, and finally exploding under the car like a ton of dynamite, scaring all the passengers out of a year's growth. The cases in Brooklyn proved to be very similar. In the Sunday *Sun* (N. Y.) of Aug. 25th on page 7 is an article headed "Weird Jersey Lightning" which seems to be written by the same man, as does also the Norwich story already referred to. The lightning reporter and the sea serpent reporter seem to be engaged in an inventive intellectual contest this year with the lightning reporter considerably ahead at present writing.

A. E. DOBBS.

BROOKLYN, N. Y., Aug. 26, 1895.

"VERY GOOD."

MR. C. DOUTRE, the electrical engineer of the Ontario Navigation Co., Montreal, Canada, writes us: "The Data Sheets you are at present issuing are very good; they save a lot of time and labor."

"NEATNESS AND EXCELLENCE."

Mr. Harry Linwood Tyler writes us from his laboratory at Corning, N. Y.:—"I herewith enclose check for the renewal of my subscription. You are to be congratulated upon the neatness of make-up and excellence of matter embodied in your valuable publication."

"MUCH PLEASED."

Mr. R. J. Feather, of Milnrow, Lanc., England writes us: "Have been much pleased with your paper lately; think your Data Sheets are O. K., but would like to see them with greater regularity. I have enjoyed reading your paper * * and find it, to my mind, superior to all."

MISCELLANEOUS.

MELTING IRON BY ELECTRICITY.

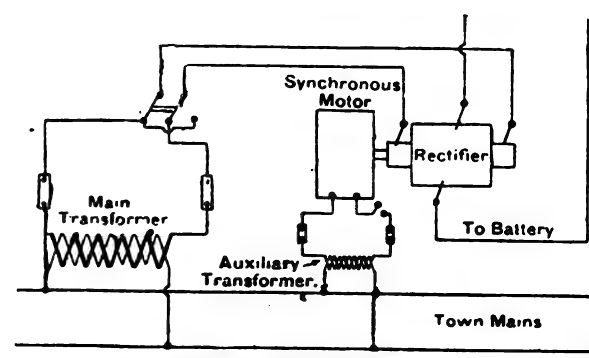
Gustaf DeLaval.

MR. GUSTAF DELAVAL, the inventor of the rotary steam engine which bears his name, is reported to have discovered a method of smelting iron directly from its ores by the aid of the electric current. Large iron works have been purchased in the provinces of Norrland and Wermland, in northern Sweden, the two great iron districts of the north, together with immense water privileges and vast deposits of peat to be used as fuel. If this process should prove commercially practicable, its influence on the iron industry can hardly be overestimated.

CHARGING ACCUMULATORS BY ALTERNATING CURRENTS.

An account is given in a recent number of the *Zeitschrift für Electrochemie* of a method employed by Herr C. Pollak for charging accumulators by means of rectified alternating currents.

The requisite apparatus for converting an alternating current of high voltage into a uni-directional current of low voltage consists of a main step-down transformer and a small auxiliary transformer, which drives a synchronous motor, having a commutator on a prolongation of its spindle, to which current is led and from which it is taken, after rectification, by appropriate brushes. The whole arrangement is clearly shown in the accompanying figure.



POLLAK'S ARRANGEMENT FOR CHARGING STORAGE BATTERIES FROM ALTERNATING CURRENT CIRCUITS.

By adjusting the set of the brushes the flow of current to the accumulators can be stopped at such part of each alternation as to avoid reversal.

At the Pollak Works at Frankfort the town supply of current at a pressure of 3,000 volts is transformed down to 65 volts and rectified as described above, the resulting uni-directional current serving for general electrolytic purposes as well as for driving ordinary direct-current motors. An efficiency of 96 per cent. is claimed for the rectifier, 2 per cent. loss being encountered in driving the small synchronous motor, and 2 per cent. in contact resistance.

ACTION OF THE SOIL ON IRON POLES, PIPES AND CEDAR POLES.

The *Annual* of the Engineering Society of the University of Michigan, gives some interesting information relative to the rusting of iron poles and the rotting of wooden ones. Experiments with ordinary 4-inch gas pipe used as trolley poles, and set in concrete up to the surface of the ground, without other coating, developed that they would become corroded through at about 10 inches below the surface in about three years, forming a black deposit. The life of white cedar poles in the clay soil of Detroit is said to be about 18 years, without protection or treatment of the butts. Norway pine poles have lasted in the same soil about 30 years, but were badly rotted at the surface line. They, however, rot very soon in a sandy soil. The more pitchy ones decay first. Winter cut poles and those cut in summer with the sapwood removed are more lasting than those containing green sapwood. It is reported that steam piping, covered with a nonconductor, and maintained at a temperature from 250° to 300° Fahrenheit, though buried in the ground, will not corrode, while a hot water return at 212° Fahrenheit, similarly covered and buried, would corrode from the outside by rusting.

CONTENTS.

WHAT THEY WANT IS LIGHT.

THE past five years have not been marked by any radical changes in the methods of electric light distribution, and this condition of affairs has acted beneficially in so far as it has given more time and opportunity for bringing the present apparatus up to the highest state of efficiency. Nevertheless certain tendencies have begun to manifest themselves, which bid fair to have some influence on the future of incandescent lighting. We refer more particularly to the increasing use of the 25-candle lamp in place of the original standard 16-candle lamp. In order to appreciate fully the causes for this increase in candle-power now demanded, we must go back to the time when the commercial incandescent lamp made its appearance. At that time "20-candle" was the standard for gas illumination, and even that figure was reached in but comparatively few localities. When Mr. Edison adopted the 16-candle standard for his lamp he took what was probably a very good average of the illumination given out by 5-foot gas burners, the country over. The last fifteen years, however, have witnessed great improvements in gas manufacture, and whereas 20-candle gas was once a comparatively rare commodity, the larger cities of this country now average well up to 25-candle gas. Light consumers have not been slow to observe this fact, and it behooves the central station manager who has an eye to the future to be ready to meet the new condition of affairs. It will not do for the electric light man to argue that with a given number of 16-candle power incandescent lamps properly distributed the same illuminating effect can be obtained as with the smaller number of 25-candle power gas burners. He ought to be prepared to give his customer a unit of light at least equal to the prevailing standard gas unit. This view of the case is, we have reason to believe, beginning to gain ground, and added to it is the growing tendency to use high economy lamps. That the preachings of the lamp manufacturers have not been in vain is shown by the fact that the time-honored 600 hours of life is not nearly so often insisted on as formerly. Indeed, the specific requirement now demanded in not a few instances is a lamp that will maintain its candle power, at high economy, for from 300 to 400 hours.

We must not, of course, lose sight of the fact that the greatly reduced price of incandescent lamps has enabled the lamp consumer to carry out his ideas in this direction and to give his lamps a short and merry life in preference to the former lingering death. The introduction of 25 candle power lamps will doubtless be a gradual one as it must naturally be accompanied by a corresponding change in the fittings, cut-outs, wiring, etc., if applied to existing installations. But new work will probably be designed *ab initio* to conform to the coming order of things. In contrast to the demand for brightness and high illuminating power in lamps in this country, is the conservative European practice of employing 10 c. p. lamps as the standard. We are not aware that the number of lamps to light a given space abroad is much if at all greater owing to the lower illuminating power of the lamps employed, but must assume that Europeans are not given to liberality in lighting any more than in other items of daily expense. There is also some reason for believing that the satisfaction given abroad by the 10 c. p. lamp is due to the fact that the lamps are kept well up to candle power, a condition which has not invariably obtained in our own country.

THE DEADLY SHADE TREE.

One's feelings of indignation are sometimes aroused to see beautiful old shade trees mutilated or chopped down to make way for electric light poles, or trolley circuits, or even for houses; but there does appear to be also another side to the question, according to which the shade tree is often both pernicious and deadly. In fact, the contention might be urged that the trees are distinctly foes to health in many cases; at least abundant experience in Brooklyn, Cleveland, &c., points that way. But Mr. Alex. Dow, the electrician of the Detroit municipal lighting commission, now complains of the shade trees in that city as a decided nuisance. They are planted much too thickly, and when grown are left uncared for, so that their stems are stubby and their foliage is a clumpy sponge. They not only shut out the electric light but God's own sunshine. It is difficult to get wires or lampposts under them, but the illumination from towers cannot penetrate downward through their black masses of summer foliage, while in winter their bare arms are constantly breaking and falling upon the streets, the houses and the circuits. To this it might be added that they harbor noisy sparrows and hairy caterpillars that are always dropping down one's back. Even the glorious avenue of elms and chestnuts in East-hampton, Long Island, the pride of every artist, keeps the broad road wet and muddy long after the surrounding country has dried up, and gives a damp, clammy feeling to the atmosphere. We agree with Mr. Dow that the shade trees need regulating more than the poles and wires do.

SENDING THE MAILS BY TELEGRAPH.

We gave some interesting figures last week relative to the rapid growth of telephony and the fact that the long distance service has become a formidable competitor with the telegraph for some of the most profitable business. Indeed, it was shown that taking the two industries broadly, the telephone is ten times as often used as the telegraph, and that while the telegraph does not increase appreciably in the ratios of its use by the public, the telephone habit is gaining ground in a most remarkable manner. To-day, the population of the United States does not average annually much more than one telegram per head, whereas the telephone average is already ten messages per year, per head. When we realize that already in large cities, the ordinary subscriber uses his telephone ten times a day, and that only now have the suburban and rural portions of the community begun to enjoy the enormous advantages of the telephone, it will be seen that the telephone in frequency of use bids fair to leave the telegraph so far in the rear, that comparison will become ridiculous. Moreover, we record this week the use of the long distance telephone wholesale for convention news purposes, thus sapping the vitals of the telegraphic news systems of the Associated and United Press.

But there are those who contend that the telegraph has not yet been made to yield its full measure of usefulness, and chief among these experts to-day is the veteran telegrapher and inventor, Mr. P. B. Delany, who now proposes that the mails shall hereafter be sent by telegraph instead of by train and star route. With his permission, we print this week his pithy and striking argument on the subject. We recommend a careful perusal of his ingenious plan for expediting the mails. There can be no denying that Mr. Delany's views are sound in the main, and that to come up to the needs of the present hour, the telegraph demands distinct improvement or remodeling. The blue ten cent special delivery stamp on a "rush" letter is at once a condemnation of the slowness of the mail system and a confession that the telegraph has not yet been carried to the point where it can profitably intercept for itself the 12 cents total mail postage. But as Mr. Delany ventures to predict, two good copper wires fed with mail matter, on his plan, might be made to carry 28,800 messages of 50 words each per day between New York and Chicago, with a remarkable margin of profit and with an immense acceleration in the transaction of business. There appear to be upwards of 40,000 letters carried daily between the two cities, so that Mr. Delany counts on capturing a large proportion of that correspondence. How far his surmise is correct we will not undertake to say, but it seems to us that there would be an offset in the fact that many telegrams now exchanged at high rates would at once come within his reduced scale and thus lessen the existing telegraph income.

Mr. Delany's method of transmission is based radically upon the supercession of the dash by a system of double dots combined with the familiar single dots. He says that a single copper wire of only 300 pounds to the mile thus machine-worked between New York and Philadelphia will carry 3,000 words per minute, whereas by the present hand system, 38 wires must be worked quadruplex, or 152 circuits, at about 20 words per minute. If true, this is decidedly interesting, and if true, we do not see how an intelligent telegraph manager, beset by the telephone, can resist its appeal to his spirit and his desire for profit. It is noteworthy that Mr. Delany's scheme embraces the transcription of the tape at each end by the typewriter and the delivery by mail; but why could not the letters then be telephoned to everybody who has an instrument in his house or office? It would be a further economy of time and cost.

COPPER SHEATHING FOR SUBMARINE LIGHTING CABLES.

In commenting on the employment of copper wire armor employed in cables recently installed for conveying current to the electric buoys in New York Harbor, our excellent contemporary, the London *Electrical Review*, remarks that it does not quite see the advantage of copper, for the durability of copper in sea water is questionable, owing to the formation of the oxychloride which peels off. Our contemporary has evidently not weighed other factors involved in this unique installation. Without taking into account the relative life, under sea water, of copper and iron,—regarding which, by the way, we do not agree with our contemporary,—the question of practicability entered largely into the problem. It will be recalled that the current is alternating and is led to transformers placed on each buoy. Experiments at the Columbian Exhibition in 1893 had shown the enormous drop in the conductor with an iron armored cable, due to impedance produced by the surrounding iron sheath. It became a question therefore of a two-conductor iron armored cable, or to find some other method of protecting the insulated conductor. As two insulated conductors were not necessary, hard drawn copper wire was selected as the armor. This has the advantage not only of obviating all impedance but also of offering a low resistance path for the return current. The new New York Harbor electric buoy system is deservedly attracting much attention and its successful operation will probably be followed by similar harbor lighting, both here and abroad.

ELECTRIC TRANSPORTATION DEPARTMENT.

TO IMPROVE CHICAGO STREET RAILWAY PRACTICE.

Mr. C. L. Bonney, president of the West and South Town Street Railway Company, and vice president of the Chicago General Railway Company, returned recently from a three months' tour of the capitals of Europe, where he has been studying city railway transportation. Mr. Bonney was entertained by the transportation companies of nine European capitals and was offered every courtesy and assistance to his investigations.

"The object of my trip was to obtain information in the principal cities of Europe as to the operation and control of street railways and to gather material to be incorporated into a general ordinance, which we intend to draw up and place before the city council, based upon the police regulations of street railways in the old world, where they are operated from the best public standpoint of any in the world. Here in Chicago the individual roads are told to do this and that by the municipal fathers. It is 'South Side company, do this,' and 'West Side company, do that.'

"We contend that this is all wrong. The government can't pick out an individual and say 'do this' and 'do that.' It is the same in the case of corporations. While the governments of Europe are in themselves individual governments, ours is supposed to be one of equal rights. My object was to get at the systems of the old world and embody the principles which I found into a general ordinance to regulate all street railway companies of the city. I found in existence there one ordinance which requires that any conveyance used by street transportation companies be approved by the police department before it is allowed to run. Under this law the police department requires that every passenger shall have a seat. Here what there is of this sort of inspection is done by the commissioner of public works. It is not his business.

"Our policy will be to attempt to make it a police regulation and under the control of the superintendent of police that people shall not be packed into cars like sardines. Some Chicago companies say they can't carry everybody and give everyone a seat. One of the London companies carried 33,000,000 passengers last year and gave each person a seat. A Berlin company carried over 30,000,000 in the same way.

"Over 90,000,000 passengers rode in London on the various lines last year and each one had a seat. That is more than the number carried in Chicago last year. These London and Berlin companies are all subjected to a severe competition. Chicago companies have no competition. They have a monopoly of the business. Under police supervision of city transportation everyone who rides would have a seat. Any company which claims that it can't do this is trying to mislead the public. The secret of the thing is that it costs less money to pack people into cars like cattle. In St. Petersburg and Moscow seats are provided on the top of all cars, and one wishing to go up pays a half-rate. In short, there isn't a capital in Europe where the police allow crowded street cars.

"From a public standpoint, the management of Chicago's street railway system is worse than that of any of the cities I have visited. Another police regulation in Europe is in regard to horses used to draw cars. If a protest is made by the department of police in regard to an animal which is unfit for work for any reason there is no trial or long process of law, but that animal is taken back to the barn by the conductor and left there. It is the law and it is carried out. No question of private ownership is raised.

"Do they declare a dividend? Are there any profits? Well, I should say they did. The London company of which I have spoken carries its passengers at an average fare of 3 cents. A good surplus has been set aside and an 8 per cent. dividend is paid yearly on its stock.

"You can ride through the heart of London, from Charing Cross to the Bank of England, a distance about as great as from the water works to Twenty-second street, for 1 penny—2 cents. The long-distance rides cost more. The highest is 4 pence—8 cents. It would be to the interest of the companies using the graded fare to make a uniform fare for all distances. In carrying 33,000,000 the company of which I speak was required to print and check up 150,000,000 tickets. When a man pays his fare he is given a ticket, the checking up of which requires an enormous

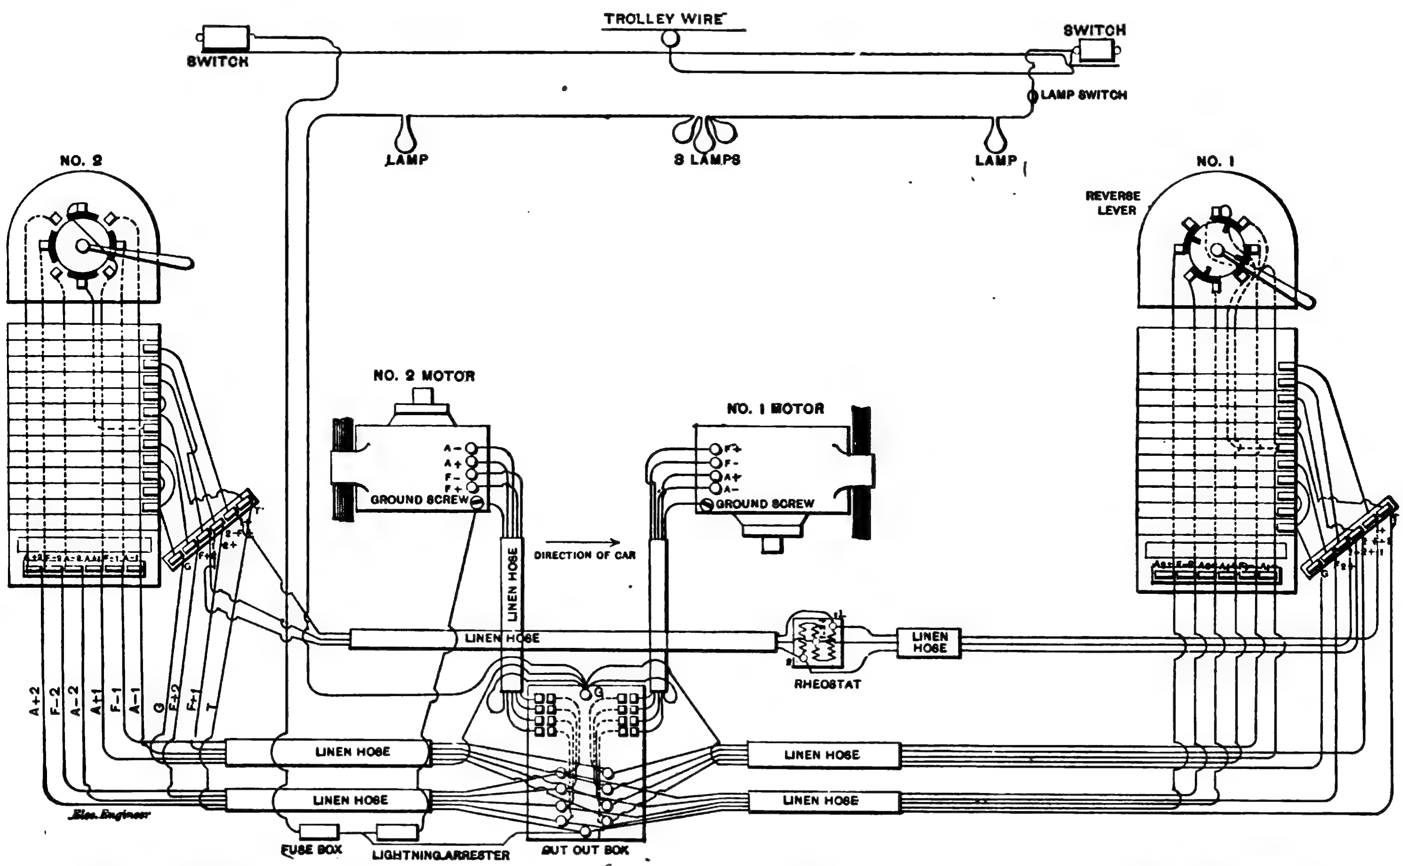

FIG. 3.—DIAGRAM SHOWING CONNECTIONS AND CAR WIRING WITH SERIES PARALLEL CONTROLLER.—*(See Page 235).*

expense for clerical work. A large profit is thus eaten up. All of this has to come out of the 3 cents a ride.

"In Paris omnibuses, street cars, storage batteries, electric and compressed air motors are used. The rates are the highest there of any in Europe."

ELECTRIC CAR WIRING.

In an interesting lecture given before the Brooklyn Electrical Society, Mr. Daniel O'Mahony described the operation of electric cars, and gave in detail the method of wiring, illustrating his remarks with diagrams of the Westinghouse car wiring plan.

The regulation for speed is obtained by means of the series parallel controller, Figs. 1 and 2 showing the various connections diagramatically. The numbers represent the following combinations:

1. The two motors and rheostat are connected in series. 2. The motors and half the rheostat are in series. 3. The two motors are in series. 4. The two motors are in series, with the rheostat in shunt with one of them. 5. The motors are in series and half the rheostat in shunt with one of them. 6. The motors are in series, with a dead shunt around one of them. 7. One motor working. 8. Motors in parallel, the rheostat in series with one. 9. Motors in parallel, half the rheostat in series with one. 10. Motors in parallel.

The diagram, Fig. 3, shows the wiring of the car, and illustrates the action of the controller and reverser, which is shown in plan above the controller.[1] The controller No. 1, shown at the right, has the reversing lever set for the car to go "ahead." At the left, No. 2, the lever is set in the position when the car is not working. Following out the wiring, A + and A — designate the wires connected to the armature binding posts respectively; and the figures 1 and 2 refer to the motor to which the respective wire is connected. Thus, A + 2 means the wire connected to the positive terminal of the armature of No. 2 motor. In the same way F stands for the field connections with the same numerical designation, and G for the ground wire. There are in all 13 wires

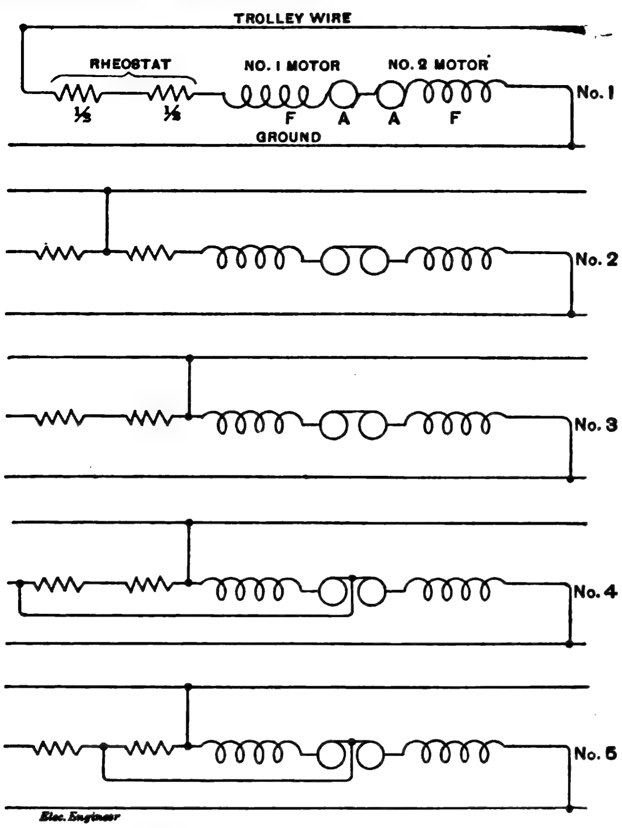

Fig. 1.—Series-Parallel Controller Connections.

going from controller to controller; 8 motor wires, 3 rheostat, 1 trolley and 1 ground wire. These wires are joined to their respective binding posts in the cut-out box, except the rheostat wires. There are also short wires going from the binding posts to the motors and ground, and one wire which goes to the trolley pole. This latter wire is led to the fuse box and passes through two overhead switches, and through a fuse box, so that when the switches are turned on the overhead wire is in direct contact with the controllers. The ground wire is grounded on the motor, which rests on the axle, current passing through the wheels to the ground.

Tracing the current from the trolley wire to the ground it first passes down the trolley pole to the cut-out box; from there to the controller and enters the ring of the cylinder which makes contact with the trolley finger on the back; passing into the contact marked 1 + the current flows through the wire to the rheostat binding post 2 —, and then by wire F + 1 to the contact on the controller 2 — F +. From there the current is led around the field magnets, returning by wire F — 1. Thence through the medium

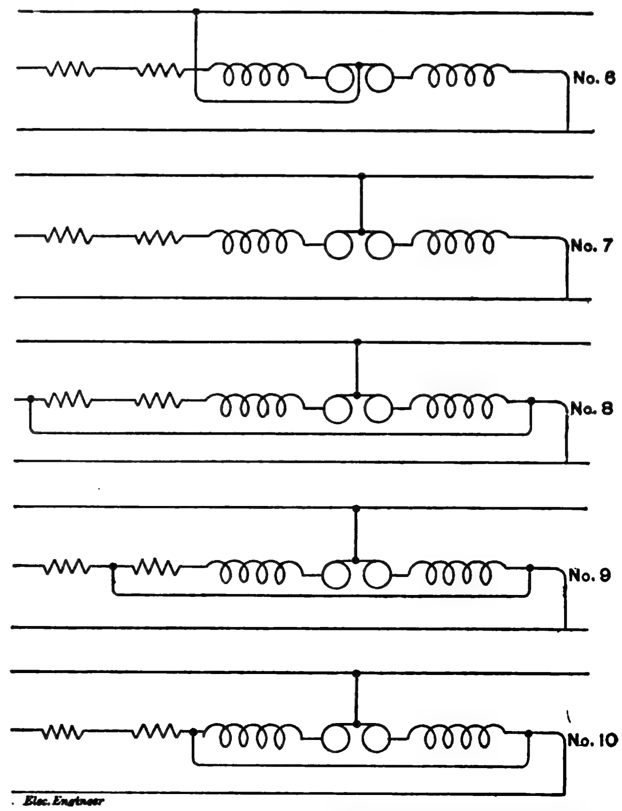

Fig. 2.—Series-Parallel Controller Connections.

of the reverser the current passes over the wire A — 1 to the armature, returning by A + 1. The reverser joins this wire to A — 2 which carries the current to the armature, returning by A + 2 which is connected to F — 2 in the reverser. Current flows through this wire around the field magnets returning by F + 2. This wire is connected with a finger which is in contact with a ring on the cylinder; this ring is connected with the ring below it which makes contact with the ground wire G. The current flows through this wire to the cut-out box, and then to the ground screw on the frame of the motor. As the motors are placed in reversed position on the axles the connections must be such that the current passes through them in opposite direction, in order that the armatures may rotate in the same direction, which is necessary in order to have them work in unison.

1. Through an error of the engraver the wires connecting to the Reverse Lever No. 1 are incorrectly drawn. The connections are, however, identical with those of Reverse Lever No. 2 shown at the left.—Eds. E. E.

A VICE CHANCELLOR DENOUNCING TROLLEY ROADS.

After hearing both sides on the petition for an injunction to restrain the New Brunswick Trolley Company from building an electric railway line between New Brunswick and South Amboy, Vice-Chancellor Pitney, of New Jersey, granted a temporary restraining order and also a rule to show cause why a permanent injunction should not issue, the same to be returnable on September 3.

The Vice-Chancellor also took occasion, in giving his decision, to denounce trolley roads in general. He declared that electric companies were in the habit of going to work and tearing up roads and laying down their tracks at night the moment they were granted a franchise, so that they could plead, when action was brought against them, that the nuisance, if nuisance it should be proved, existed already and was not about to be placed there, but he did not propose to accept any such argument, although he would be bound to decide the subject according to the law.

The Vice-Chancellor said that the companies, so far as he could learn from observation, invariably obtained desired franchises if they kept pressing their petitions long enough, and that then they appropriated the highways and went thundering along them regardless of the wishes of the people. He called this

downright robbery, and said the companies should be made to pay. If it could be shown that the proposed electric road on the narrow roadway would spoil that street for the use of other vehicles, which he was willing to believe it would, he should grant the permanent injunction.

Mr. Pitney said the insertion of a clause in the ordinance limiting the speed on the proposed road to twenty miles an hour indicated that it was intended to run the cars at that speed, which would clearly be as dangerous as steam cars.

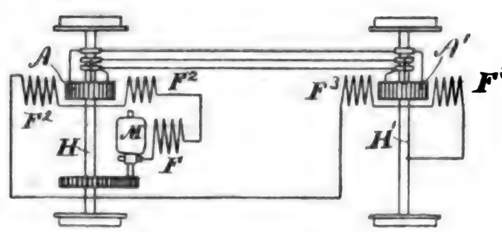
THOMSON AND RICE'S METHOD OF SYNCHRONIZING RAILWAY MOTORS.

It is a matter of common observation that owing to unequal loads at the two ends of an electric car, or the condition of the track, the wheels at one end may slip, while the wheels at the other, having firm adhesion, drive the car. In this case, one of the motors will race, and because the motors are in series the current will be cut down by counter electromotive force, so that the single motor becomes unable to drive the car, and if the slipping be prolonged the car may even come to a stop.

One of the methods tried for overcoming this difficulty, has been the connection of the motors by cranks and connecting rods; but this has not proved entirely successful in the past. When applied to cars having swivel trucks, as is usual in long cars employed for heavy traffic, the mechanical difficulties make the method prohibitive.

To secure the desired co-action of the motors on a car, Prof. Elihu Thomson and Mr. E. W. Rice, Jr., have devised a method by which the motors are maintained at synchronous speed electrically, just as if they were connected by mechanical means. The arrangement is, of course, applicable to a variety of work, but that specially adapted for electric cars is shown in the accompanying diagram.

In this figure the armature M of a continuous current motor is



Thomson and Rice's Method of Synchronizing Railway Motors.

geared to an axle H. Upon this axle is placed directly a second armature A, energized by field-coils F^2 F^2 in series with the field-coil F, energizing the armature M. Upon the second axle H^1 is placed another armature A^1, furnished with field by the coils F^3 F^3, also in series with the other field-coils. These armatures A and A^1 are wound on the multiphase system only, and are connected by collecting-rings and leads.

The operation of the device is as follows: The continuous current armature is driven by the line current, and acts also as a generator of multiphase currents through the collecting-rings and leads. So long as the speed of the two armatures A A^1 is the same, the two electromotive forces in the multiphase system balance and no current passes; but should one increase in speed a difference of electromotive force is produced, and one machine generates a current driving the other as a motor, tending to maintain synchronism of rotation. At the same time the loss of energy in the driving-armature acts as a brake to slow it down until the opposing forces again balance and the two armatures revolve at the same speed. The greater the difference in speed the higher the opposing force, and as the effects are practically instantaneous and the resistance of the leads and armatures comparatively small unison of revolution is secured.

Such an arrangement is particularly adapted to the high-power locomotives required in trunk-line business, as two, three, or even more motors may be employed without mechanical connections between the driving-wheels, the armatures insuring unison of action and equal distribution of strain over the framing of such high-power machines. It is manifest that reduction gears may be introduced into such a device, or the motors might be located on different parts of the train and their synchronism maintained.

NO RIGHT TO USE ANOTHER ROAD'S TRACKS.

An important railway decision was rendered by Judge Tuley of Chicago recently in the suit of the General Electric Street Railway of that city to compel the Chicago Street Railway Company to allow the electric company's cars to run a short distance over the Chicago's lines. Judge Tuley decided against the General company, holding that the railways are not public property, and can be controlled exclusively by the company operating them.

PEOPLE WHO WANT TO GO SLOW.

Apropos of the fast time made by the racing trains between London and Aberdeen, London *Engineering* says:

It will be remembered that the railway race to Scotland in 1887 caused many old ladies, mainly of the male sex unfortunately, to vent their alarm in the newspapers. We note that the accelerated service to Paris is calling forth quite similar effusions. Thus Mr. E. Henry Lee, of Birmingham, writes to the *Times* protesting against the high speed on the French lines near Calais, stating that a wagon of a train in which he was traveling got off the rails there. No harm was done, it appears, as the brakes pulled the train up without damage. As there are plenty of slow trains, it is difficult to understand why individuals who are afraid of high speeds do not travel by them, instead of writing to the papers with a view to inconveniencing those who like to reach their destinations quickly, and are prepared to accept any slight additional risk involved.

STORAGE BATTERY CARS FOR PHILADELPHIA.

It is announced that the Southern Passenger Railway Co., to operate the Carpenter and Reed street lines in Philadelphia, will in all probability equip its road with storage battery cars, each car to have battery power for a run of 70 miles.

DECLINING TO CARRY THE MAILS.

The directors of the Springfield, Mass., Street Railway Company have voted not to accept the United States Government proposition for the transportation of mail. This is the first case of refusal on record on the part of a railroad corporation.

IS ANYONE ANXIOUS TO PAY FOR COPPER RAILS?

Copper rails!

What a throbbing thrill of anticipatory joy coursed through the veins of the copper bulls as this novel and pregnant suggestion was made upon the "street" yesterday.

"Copper men say that it is found that steel rails under ground rust and become damp, which dampness operates against the conductivity of electricity, and consequently there is talk of adopting a hardened copper rail."

This was the sum and substance of the news item that found its way into the quiet precincts of the brokers' offices yesterday, but its latent possibilities could not be hidden by the modesty of its phraseology, and the copper enthusiasts straightway began to figure out how many $12 dividends a month Boston & Montana, or Quincy, or Osceola would pay to their fortunate owners if the steel rails of the country should be replaced by hardened copper ones at 15 cents a pound.

Just as they were figuring along this line another stray news item came over the wires to the effect that western railroads are buying 30,000 tons of steel rails this week alone, and that negotiations for 18,000 tons more are under way.

Now, if these 48,000 tons were only tons of copper!

But the thought was too seductive to dwell upon very long, and with mingled hopes and fears as to the reality of the vision, the traders returned to their everyday task of hammering or elevating Montana.

Perhaps this is why the copper producers are holding off for 18 cents a pound? If racing yachts can be sheathed with aluminum, or covered with Tobin bronze, why not copper rails and copper ships?—*Boston Globe.*

The New Brunswick-Millstone Branch of the Pennsylvania Road is the next, it is said, to be equipped electrically. It has been run at a loss of about $10,000 a year, but the change will not only enable it to compete with the new trolley lines, but, it is said, put it in condition to earn a small profit.

The Street Railway Men of New England, to the number of 75, had a pleasant gathering on August 21, visiting Newburyport and dining at the Pines on the Merrimac.

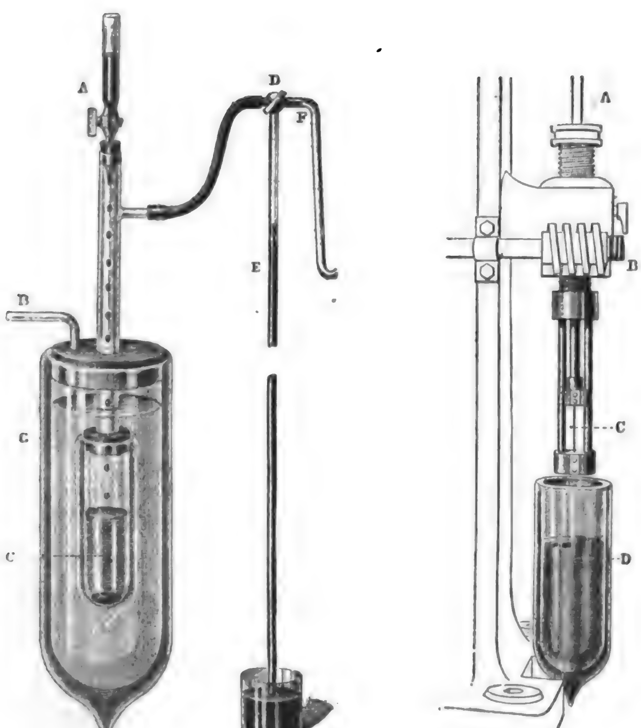
"STANDARD."

The New York Electrical Engineer is full of interesting matter. This is the oldest electrical journal in America, and is sought after far and wide by all electricians. It takes advanced ideas upon electrical subjects, and has won for itself the name of the Standard Electrical Journal.—*Kansas City Architect.*

SCIENTIFIC USES OF LIQUID AIR.[1]—III.

BY PROF. J. DEWAR, F. R. S.

The same principle is used when the latent and specific heats have to be determined. Fig. 5 shows the general plan of the apparatus. Now a definite quantity of heat has to be conveyed into the inner vacuum vessel containing liquid air, with the object of finding the weight of liquid that distills off on the one hand, or the elevation of temperature in the liquid that takes place on the other. For the purpose of adding a given quantity of heat it is convenient in some cases to use mercury (as represented in the figure), or to lower a piece of platinum or silver, or even glass, into the inner vessel; each unit of heat supplied evaporates a definite amount of air, which is readily ascertained by collecting the gas which comes off during the heat conveyance. In Fig. 5, A is the mercury, C the inner vessel of liquid air, D a three-way stop-cock, F a tube for collecting the air given off; E is a barometric tube for observing the pressure when the inner vessel is exhausted. In a latent heat determination all that is necessary is to weigh the mercury added, and to measure the amount of air by volume which has distilled from the liquid state. If the specific heat of the liquid is wanted, then the inner vessel is exhausted (as well as the outer) through the tube F to about ½ in. pressure, and the three-way stop cock turned so as to shut off F and connect the inner vessel with the manometer E. Mercury is now dropped into the inner vessel until the manometer rises to the atmospheric pressure or the liquid reaches its boiling point under atmospheric



FIGS. 5 AND 6.

pressure. Care must be taken to prevent the drops of mercury falling exactly in the same place, otherwise a mercury stalagmite grows up rapidly through the liquid, vitiating the results. Another objection to the use of mercury arises from the drops causing the rebound of small liquid air drops, which strike the cork and get evaporated away from the main body of liquid. The amount of mercury added conveys the necessary amount of heat needed to raise the given amount of liquid from its boiling point under ½ in. pressure to its boiling point under 30 in. The relative pressures give the temperature range, and the weight of liquid air or other gas under observation is easily ascertained, together with the weight of mercury added. In this way the latent heat of liquid oxygen at its boiling point is about 80 units, and the mean specific heat between —108 deg. and —182 deg. is 0.39.

Seeing that the most powerful chemical affinities are in abeyance at very low temperatures, it is a matter of great interest to ascertain what change comes over the physical force we name cohesion.

Here we are dealing with the molecular forces which are effective in uniting together the particles of solid bodies, in contrast to the force we name chemical attraction, which exists most characteristically between dissimilar molecules. Both are alike in this respect, that they are insensible at sensible distances. If we accept the theory of matter which regards finite heterogeneousness of the most homogeneous bodies as proved, then Lord Kelvin has shown that gravitation alone would account for the so-called cohesive forces. Thus, he says ("Popular Lectures," Vol. I. page 60): "But if we take into account the heterogeneous distribution of density essential to any molecular theory of matter, we readily see that it alone is sufficient to intensify the force of gravitation between two bodies placed extremely close to one another, or between two parts of one body, and therefore that cohesion may be accounted for without assuming any other force than that of gravitation, or any other law than the Newtonian." Another view of the cohesive forces is taken by Mr. S. Tolver Preston, in his work entitled "Physics of the Ether," page 64. He says, "The phenomena of 'cohesion,' 'chemical union,' etc., or the general phenomena of the aggregation of molecules, being dependent on the molecular vibrations as a physical cause, it would therefore be reasonable to conclude that variation of vibrating energy (variation of 'temperature') would have a most marked influence on these phenomena, as is found to be the fact. Further, since when a physical cause ceases to exist the effect also ceases, it follows that at the absolute zero of temperature (absence of vibrating energy) the general phenomena of 'cohesion,' including the aggregation of molecules in chemical union, would cease to exist." If this theory is pressed so as to include the gaseous state, then at the temperature of —274° C. we may imagine the particles reduced to an incoherent layer of dust or powder. The experimental facts do not, however, warrant this conclusion, seeing that at the lowest temperature reached, which is about — 210° C., air remains a transparent jelly.

That a low temperature causes profound changes in the elastic constants of a metallic body is most easily shown by placing a rod of fusible metal in liquid air, and comparing the deflection produced by a weight when the rod is supported at one or both ends before and after cooling. The Young modulus is increased to between four and five times its amount at ordinary temperatures. In the same way, the rigidity modulus can be shown to be greatly changed by cooling a spiral spring made of fusible metal wire. Such a spring at the ordinary temperature is quickly drawn out into a straight wire, by attempting to make it support an ounce weight. The same spiral, cooled to —182° C., will support a couple of pounds, and will vibrate like a steel spring so long as it is cool. In the same way, a bell or tuning fork of fusible metal gives a distinct metallic ring at —180 deg. If two tuning forks are taken of identical pitch, and one cooled to —182 deg., then on simultaneously striking them beats are very distinctly heard. The simplest plan of getting some idea of the change in the cohesive force at low temperatures, is to ascertain the tenacity or breaking stress of the metals and alloys under such conditions, and to compare such results with similar experiments made at the ordinary temperature with the same metallic samples, using the same apparatus. In this way the comparative values are reliable. The only difficulty is the large quantity of liquid air or oxygen required to cool the steel supports of the wires, which have to be broken. Seeing that wires less than one-tenth of an inch in diameter are unreliable, good strong rigid steel supports are needed, and as these have to be cooled each time a wire is broken, the experiments involve large quantities (gallons) of liquid air and oxygen. Further, as not less than three, and in many cases six experiments must be made with each sample of wire, and the stress in each case can only be applied slowly, work of this kind extends over long periods of time, and this means increased waste of liquid gases. Fig. 6 shows the general plan of the part of the testing machine which supports the wires which have to be broken. In the figure, A is the steel rod which is connected to the multiplying levers, the stress being gradually increased as usual by running in water into a vessel hung from the long end of the lever; C is the wire to be tested, B is an arrangement which measures roughly the extension of the wire, and D is a large silvered vacuum vessel holding the liquid oxygen. This latter vessel must be large, in order to avoid any part of the supports of the wire coming into contact with the sides, otherwise the shock of the wire on breaking shatters the vacuum bulb. The rupture must be made while the wire is immersed in the liquid oxygen, and the whole of the supports thoroughly cooled down. The wires must be caught in long V-shaped grooves made in the steel supports in order to avoid slipping, and change in the cross-section of the wire. As a rule, the wires used were one-tenth of an inch in diameter and 2 in. long. The following table gives the mean results of a large number of experiments :—

TABLE I.

BREAKING STRESS IN POUNDS OF METALLIC WIRES 0.098 IN. DIAMETER.

—	15°C.	—182°C.
Steel (soft)	420	700
Iron	320	670
Copper	200	300
Brass	310	440
German silver	470	600
Gold	255	340
Silver	330	420

An inspection of this table proves that all the common metals and alloys increase in tenacity at low temperatures; thus iron has doubled its breaking stress, and the other metals and alloys are all increased from a third to a half the normal amount. This increase of strength is solely due to the low temperature, and persists only during its continuance. Wires that have been cooled to the temperature of —182° C. and allowed to regain the ordinary temperature, are in no way changed as regards their breaking stress.

THE FISHER AUTOMATIC CUT OFF ROTARY ENGINE.

There is on exhibition in the Cadillac Hotel, Detroit, an automatic cut-off rotary engine which is claimed to be as economical in its use of steam as the best reciprocating engine and which combines some points of novelty not heretofore embodied in engines of this class. The engine is the invention of Mr. Chas. A. Fisher of Petersburg, Ill., and its dimensions are as follows:

Base 8′ x 28″; height to centre of driving shaft, 32″; extreme height 6′; total weight 2 tons; nominal horse power 50; two cylinders, diameter 12″; length 21⅛″; mean area of piston 32.25″; size of feed pipes 1½″; exhaust pipe, 3″; speed 350 revolutions per minute.

Our engraving, Fig. 1 shows the engine in perspective. Fig. 2 shows the longitudinal sections of left hand cylinder and the elevation of right hand cylinder with longitudinal sections of the steam chest valve, etc., the cut-off being removed in this view. Fig. 3 shows the cross section of both cylinders. The actuating device controlling the cut-off is a modification of a design by Richard Hartnell. This form was selected on account of its neat appearance. Any form of hyperbolic governor can be used effectually, as the range of movement for control from full load to no load, is 1⅛ inches in a straight line.

Steam from the boiler is admitted at the top of the stand S, which furnishes a support for the governor brackets and follows the passage around the steam chest D outside of the valve K¹ and is admitted at the end of the valve which is hollow. The valve is provided with two rows of perforations for the passage of the steam to the induction ports, the rows of perforations being radially opposite, and the valve driven by gear from the driving shaft of the engine in a ratio of two revolutions for the engine to one of the valve. By this arrangement the perforations alternate in furnishing steam to the cylinders and also maintain a which is half-stroke in this engine. The variable cut-off, L¹ within the valve, is arranged to be rocked by the action of the governor as the load may demand, to close the perforations in

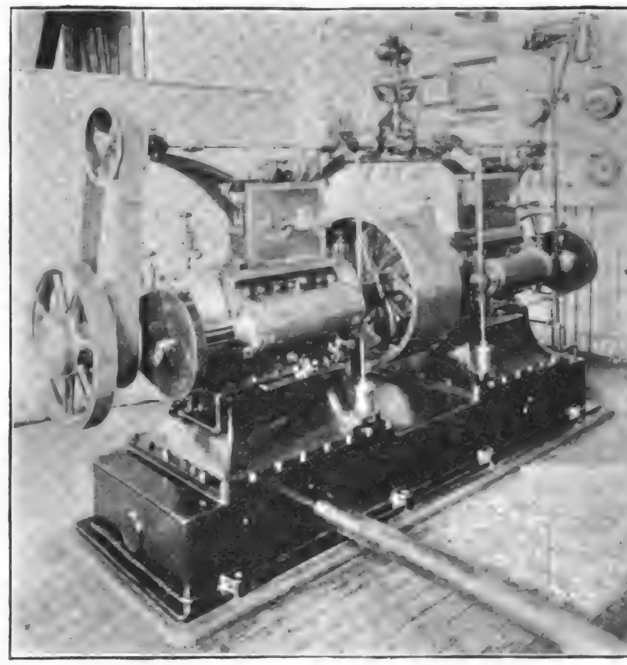


Fig. 1.—The Fisher Rotary Steam Engine.

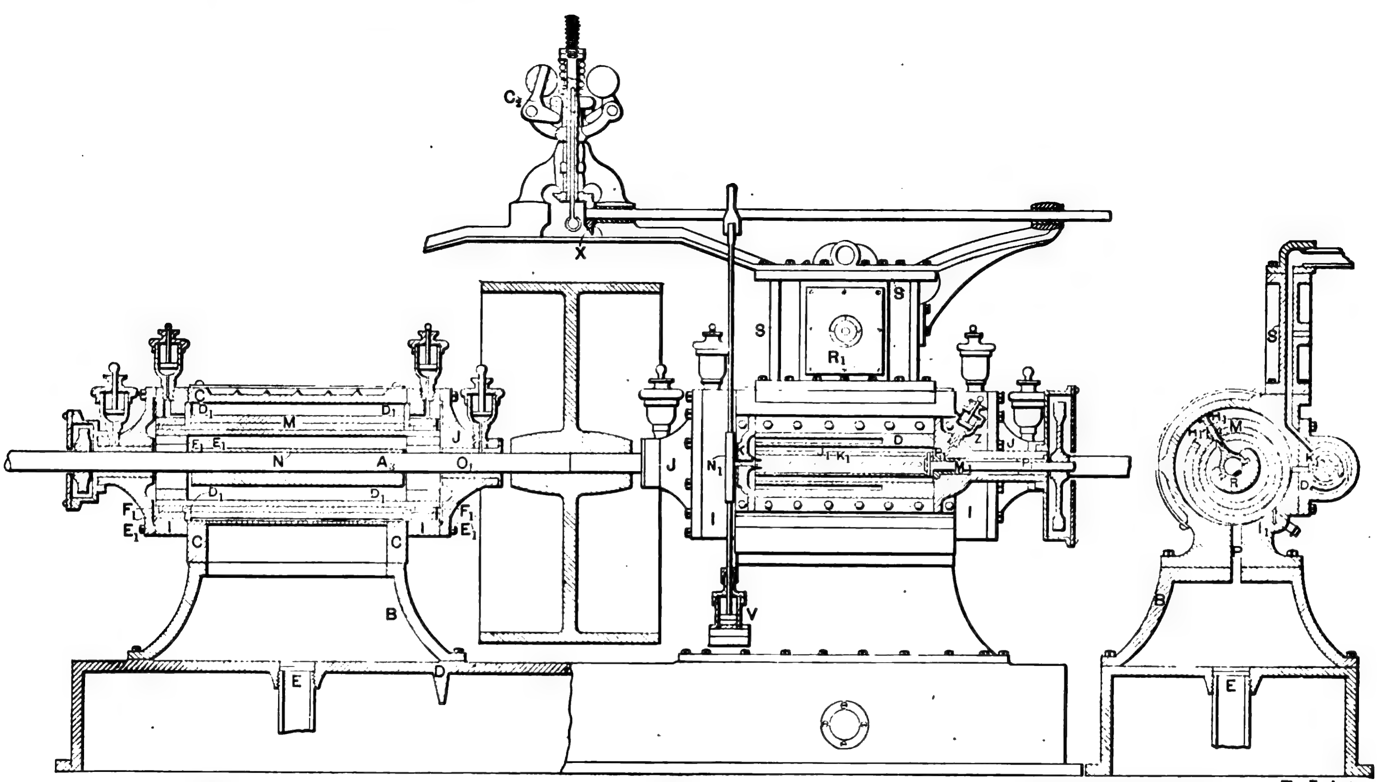
the valve at an earlier point in the stroke than would be done by the fixed cut-off.

The piston N, is keyed on the driving shaft, which is concentric with the bore of the cylinder and runs in phosphor bronze bearings 6 inches in length, located in the outer caps J. The tubular



Figs. 2 and 3.—The Fisher Rotary Steam Engine.—Longitudinal and Transverse Sections.

constant point of admission. The valve finds its seat in a cylindrical supplementary lining J¹ in the steam chest, in which is provided a row of gridiron openings covering an arc of 60 degrees in the lining.

The circular length of these openings plus twice the width of the perforation in the valve, determines the point of fixed cut-off, wheel M through which the piston passes, is mounted concentric with the bore of the cylinder, finds its bearings in the cylinder heads I, and forms an abutment with an adjustable bearing plate I¹ located in the wall of the cylinder between the induction and exhaust port.

The wheel M consists of a hollow steel shaft carrying cast iron

sleeves of equal thickness, the inner sleeve being securely fastened to the steel, the outer sleeve so constructed by a spiral "parting" as to be laterally expansible for the purpose of taking up end wear and maintaining steam joints between the chilled iron head linings D^1 with which it forms an abutment. The piston is provided with a radial T-shoe held against the inner walls of the cylinder by light springs, also with triangular plates at either end held outward laterally by springs, thus compensating for both radial and end wear. The dash pot V is for the purpose of preventing undulatory movement of cut-off.

The indicator diagram Fig. 4 was taken with the engine located 80 feet from the boiler, exhausting into the heater of the Cadillac Hotel plant, resulting in a constant back pressure of from three to four pounds. Wire drawing of thirty pounds indicates insufficient area of pipes or valve opening, and precludes an accurate estimate of results to be obtained in steam economy, but the mechanical efficiency is remarkably high, 97 per cent. being shown by the card. The indicator diagrams were made with a "Perfection" indicator adapted by Mr. Fisher for his engine by substituting the card cylinder connected to gearing by universal joints and rotating synchronously with the piston. The paper was formed in a tube to fit the card cylinder, and afterward cut longitudinally between points of admission and exhaust. The constancy of the engine as shown on the diagrams, is noteworthy, each card showing two distinct diagrams at different loads, each line of which was traced by indicator pencil not less than 20 revolutions and yet but one line was discernable.

The engine was built by the Leland & Faulconer Manufacturing

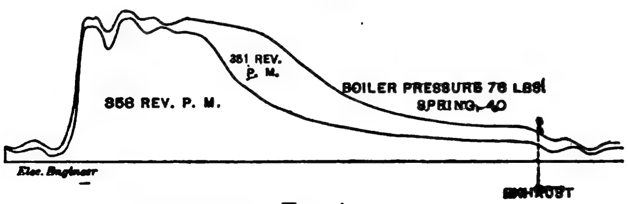


FIG. 4.

Co., under Mr. Fisher's supervision, was completed about the 15th of May and has been in constant service since that time. The first engine of this kind was built in Chicago in 1891, and was a model, the cylinder being 5" long and 5" in diameter. This little engine has been used since in the experimental laboratory of Messrs. Fisher & Abbott at Petersburg, Ill., furnishing power for their works.

Provision has been made in this engine that parts subject to most wear can be replaced at small cost; as there are no steam joints to be maintained by the use of soft packing it is calculated to require but little attention. Its construction admits of perfect balancing of all parts, a fact which makes a foundation unnecessary.

This engine can be operated as shown, or as two distinct engines as circumstances require. For the purpose of direct connected lighting or power plants of small or medium dimensions this engine can be used advantageously. Where the two engines work together, the dynamo can be placed in the centre, or where there is only one engine used the dynamo can be put at one side. The latter arrangement is well adapted for train and ship lighting where space is an object. The double cylinder engine is so set that there can be no dead centre, so that there is no difficulty in getting an engine started at any time.

It is intended to build these engines with regular fly wheels in future, those shown in the illustration being merely intended as light band wheels.

OBITUARY.

D. W. KISSAM.

The death is announced of Mr. D. W. Kissam a director of the Bridgeport Brass Co. and president of the Bridgeport Electric Co. He had been a citizen of Bridgeport since 1859, when he became connected with its brass interests. His death, at the age of 58, was due to apoplexy.

HENRY METZGER.

We regret deeply to note the death of Mr. Henry Metzger, of Pittsburgh, a veteran telegrapher and a pioneer telephonist. He was the general manager, &c., of the Central District & Printing Co., which owned the Pittsburgh exchange and a large slice of adjacent telephone territory, and took the deepest interest in the technical part of the work. He was at one time president of the now defunct Telephone Exchange Association, and also served in the Pittsburgh city council. He was unmarried but was the centre of a large circle of friends, who appreciated the kindliness and thoroughness of his nature. He was born in 1840.

PERSONAL.

MR. O. P. LOOMIS, of Bound Brook, N. J., has resigned his position as electrical engineer of the American Engine Co. of that place. There are a number of enterprises which he is considering while he is enjoying a well earned rest.

VERMONT OLD TIME TELEGRAPHERS.

Concerning the Vermont and Boston Telegraph company, the *West Randolph Herald* gives the following interesting reminiscences:—

The company was one of the first in operation and furnished from its operators many men who had done important service in the development of telegraphy. It was leased to the Western Union Company but its corporate existence is still kept up, and one meeting a year is held for that purpose.

Charles A. Tinker, the vice-president, was born in Chelsea and was the operator at Northfield in the early fifties, while Col. Robert J. Kimball was his "next door neighbor" here in our village, and Col. A. B. Chandler was taking his first lessons in telegraphy of Col. Kimball at the same time. The latter continued as an operator only a few years but has been identified with telegraph companies and has for many years been elected a director of the company for which he served as one of its first operators. Both Mr. Tinker and Col. Chandler have devoted their lives to the science and have filled some of the most important positions during their honorable careers.

While the war was in progress, they were selected as the two most trusted operators in the war office at Washington, and President Lincoln and Secretary Stanton frequently spent whole nights with them translating despatches into cipher for transmission to the heads of the army. Since then, they have been, to a great degree, responsible for the wonderful growth of the companies.

These then telegraph "boys" have made successful business men and are much respected wherever they are known. They all have homes in Clinton avenue, Brooklyn, N. Y., as well as residences in Vermont—Mr. Tinker at St. Albans, and Col. Chandler and Col. Kimball in Randolph, the home of their boyhood, where they learned the telegraph alphabet.

They have been most cordial friends for more than 40 years, and though for a while living in different states, they have never ceased to be most loyal and enthusiastic Vermonters, and enjoy their Vermont homes more than ever.

SOCIETY AND CLUB NOTES.

NEW YORK STREET RAILWAY ASSOCIATION.

The annual meeting of this Association, which does much excellent work in a quiet way, is to be held at Albany on September 17. A number of interesting papers have been prepared and a most interesting series of topics for discussion has been formulated. President Rogers, of Binghamton, reports that there is a revived interest in membership and that seven or eight roads have joined recently. A large attendance is expected and supply-men are cordially invited to join in making the occasion a great success.

PEORIA, ILL.—The Order of Railway Telegraphers has made Peoria its permanent headquarters. W. V. Powell, grand chief, and J. R. T. Auston are already in residence there.

OLD LAMPS FOR NEW.

At Camden, N. J., slick swindlers are going around claiming to be representatives of the Camden Lighting and Heating Company, and saying they were sent to place new electric light lamps in the houses of persons using electricity. They take away the good lamps and leave broken ones in the sockets.

THE ATLANTA ELECTRIC FOUNTAIN.

The lower lobe of the lake, on which the Electricity and Transportation Buildings of the Cotton States and International Exposition front, is nearly full of water and three streams from six-inch mains have been turned on the upper basin which fronts the Machinery Hall and the Mines and Forestry Building. The electric fountain is in the centre of the upper basin, and the operating chamber is complete.

THE ESSEN COAL COMPANY'S ELECTRIC MINING PLANT.[1]

BY TIMOTHY W. SPRAGUE.

A few miles from Pittsburg, at a station on the P. C. & Y. Railway called Hazletine, is the largest electric power plant for coal mining purposes in the United States, and one of the largest in the world. It is installed to operate No. 2 and No. 3 mines of the Essen Coal Company, of which Mr. J. C. Dysart, of Pittsburg, is general manager, Mr. William Baldwin, superintendent, and Mr. F. A. McDonald, engineer.

Mr. Dysart made a thorough investigation of coal mining machinery plants, and came to the conclusion that where trouble developed with such plants, it was nearly always traceable to insufficient power. Accordingly it was decided in laying out this plant to allow an ample margin of initial power.

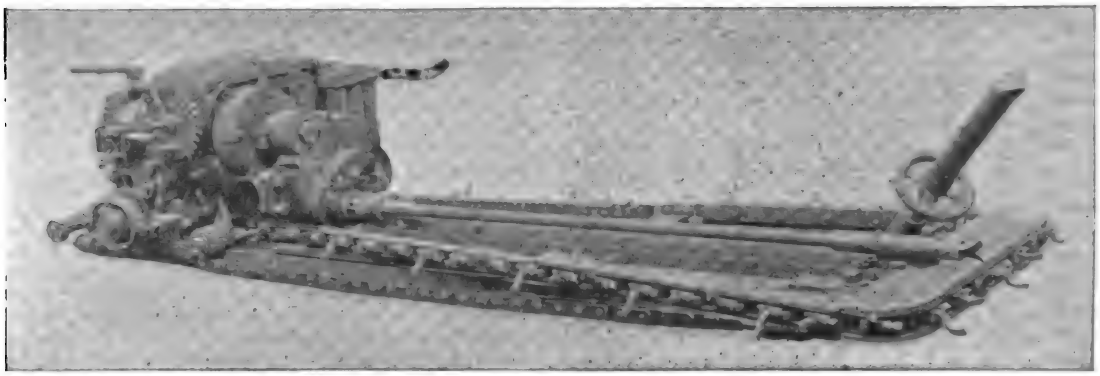

FIG. 1.—ELECTRIC COAL CUTTER EMPLOYED AT THE ESSEN COAL MINE.

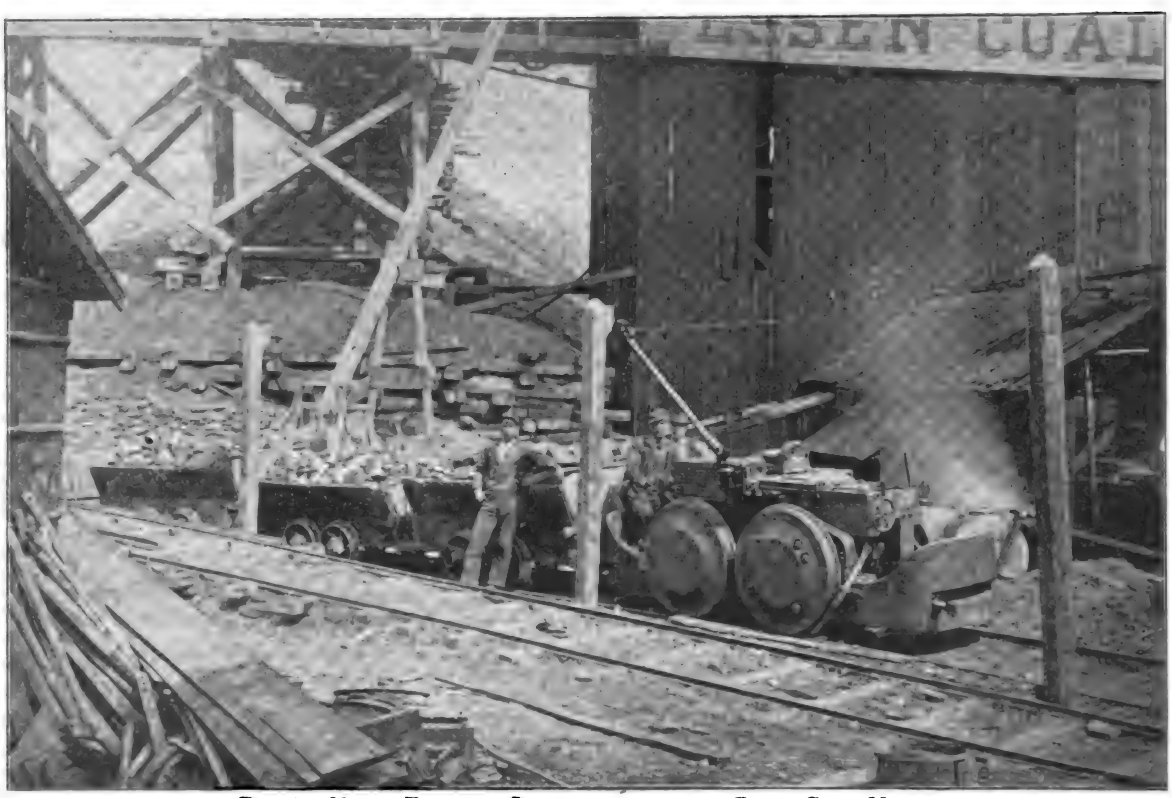

FIG. 2.—80 H.P. ELECTRIC LOCOMOTIVE AT THE ESSEN COAL MINE.

The power house itself is excellent in material and construction, and in its general design and arrangement. It is a building 130 ft. long by 56 ft. wide, steel frame with corrugated iron covering. It is set on a 15-in. brick foundation, and the ceiling of the dynamo and engine room is sheathed to prevent trouble from the moisture of condensation. The west end of the building contains four Russell tubular boilers, each 60 in. in diameter and 18 ft. long, and containing 64 tubes 3½ in. in diameter.

The engine-room, which occupies the central portion of the building through its full width is 63 ft. long. It contains three automatic Corliss engines, made by the Russell Manufacturing Company, Massillon, O., with cylinders 17 in. × 24 in., running at a speed of 153 revolutions per minute. They are set on brick foundations, and have 10 ft. fly-wheels. With the steam pressure usually carried, 90 to 100 lbs., these engines will develop something over 200 H. P. each. They drive three 150 kilowatt bi-polar generators made by the Link Belt Machinery Company, of Chicago, of the "Independent" mining type, wound for 275 volts and running at 510 revolutions per minute. These 200 H. P. generators are probably the largest bi-polar machines in use to-day. The station instruments are mounted on a marble switchboard also furnished by the Link Belt Machinery Company, which company took the contract for the entire plant, delivered and erected.

The remainder of the power house building is divided into three rooms, a blacksmith and machine shop, a locomotive house and a store room, containing a lathe and some other power tools. The locomotive room is large enough to hold on its two spur tracks the two 80 H. P. locomotives now in use. It is provided with pits for getting at the under parts of the machines and an over-head crane for lifting heavy parts.

The electric power generated is used at present for coal under cutting, haulage and lighting. The plant was started in June and is not yet in complete operation. It is intended to run 16 under cutters all of the "Independent" chain type; two 80 H. P. locomotives, one in each mine for the main haulage work,

1. Abstract from *The Engineering and Mining Journal.*

mules being employed to do the gathering, and to light the tipples, power house and underground workings as may be necessary.

The coal cutter, which the illustration, Fig. 1, shows, is driven by a 20-H. P. "Independent" motor wound for 220 to 250 volts, having but one field coil. The machine is 2 ft. high, 2 ft. 4 in. wide and 10 ft. 5 in. long when closed. It cuts to a depth of 5 ft. making the cut 3 ft. 6 in. wide and 3½ in. high. The frames of the machine are made of wrought iron and steel. The chain is cast steel, as are the sockets and socket pieces. The straps are drop forged and machinery steel pins are used for putting the chain together. Cast iron is not used in any part subject to a strain. The control of the machine is easily accomplished by the movement of a lever through 180°. By this means the cutter may be fed forward, stopped feeding, or reversed without stopping the motor. Another good feature is an automatic stop on the withdrawal. Trucks are provided for transporting the machine from room to room.

The locomotives, 42 in. gauge, are single-motor, four-wheeled machines of the "Independent" type, Fig. 2. They run under load at about 8 miles per hour, exerting nearly 4,000 lbs. draw-bar pull, and are each capable of hauling 1,200 tons run-of-mine coal per day of 9 hours from the gathering points to the bottom of the slopes in their respective mines. These distances are, in No. 2 mine, 2,000 ft., and in No. 3, 3,800 ft. The ultimate length of the main haul by the electric locomotive in No. 2 will be 5,300 ft., and in No. 3, 8,500 ft.

The coal cutters are evenly divided between No. 2 and No. 3 mines, there being eight in each. In No. 2 mine their average distance from the bank-mouth is 2,000 ft., making the distance from the power house to the machines 3,400 ft. In No. 3 mine the distance to centre of machine distribution is over 4,000 ft. At the present time in No. 3 mine 7 cutters are at work, 4 of which run 10 hours per day, the remaining 3 working double shift. In No. 2 mine, 2 cutters are running 10 hours per day, 2, 15 hours and a fifth, 20 hours.

The wiring, and in fact all the installation work, has been done under the supervision of Mr. D. N. Osyor, mining engineer for the Link Belt Machinery Company. The trolley wire is everywhere No. 00 wire, held by special "Independent" mine insulators. The only insulated wire used is in the leads to and from the switchboard and about the tipples and station, where lights are used. A ground return is used throughout, the coal cutters being operated on the grounded circuit. The rails are all 40 lbs. per yard, with fish plates, heavily bonded and cross-bonded at suitable intervals. The return is reinforced from the bank mouths to the power house by three No. 0000 aerial wires from each.

The lighting of this plant is an especial feature. In each tipple, and at all switches, etc., in the mine where a light is advisable, the special "Independent" mining arc light has been placed. This peculiar form of lamp with horizontal carbons gives an excellent illumination for underground work. The difference in the size of the carbon keeps the arc practically central, and although the lamps are run with a resistance in series, the loss is unimportant in a plant of this kind. In and about the power-house, shops, etc., 50 incandescent lamps of 16 C. P. each furnish illumination, run three in series. The locomotives are furnished with arc headlights with powerful reflectors.

BAD LANGUAGE CAUSED BY LIGHTNING.

While old Pluvius has not shed many tears in Chillicothe for some time, he has wept in the country round about, and has given an exhibition of temper, too, which made old Jupiter mad, and which was not at all to the liking of some people who saw old Zeno flash his thunderbolts. The case to which especial reference is made, occurred in South Union township, on the Egypt road, on the farm of Mr. Charles Hurst. A day or so ago the ruler of the gods sent out a streak of lightning to clear up the atmosphere, and while the aforesaid electrical fluid was on its way to earth, it came in contact with Mr. Charles Hurst's barn.—*Chillicothe, O., Gazette.*

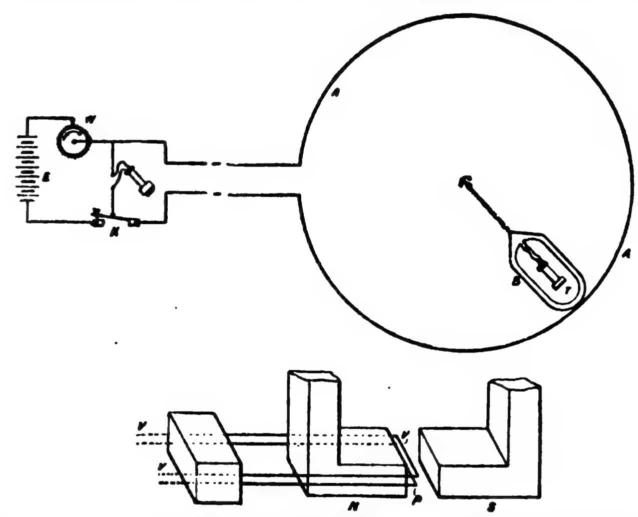
THE GREAT LAKES TO RUN SHALLOW.

It was a typically enterprising plan for Chicago to use the Great Lakes to flush out its sewerage in the new Drainage Canal, but army engineers appointed to investigate now complain that this unauthorized work, nearing completion rapidly, threatens to reduce the general lake level six inches. It would be serious if Lake cities found themselves high and dry like some of the old Cinque Ports in England. Not less serious also might be the diminution of the flow at Niagara, where last week the splendid engineering enterprise went into practical, commercial operation. The utmost that the Niagara utilization would do, it is said, is to lessen the thickness of the Horseshoe Fall about two or three inches, but this Chicago Drainage Canal is to slice six inches of water off all the Lakes, except Superior, inside of two years, and shoot the water into the already overburdened Mississippi.

ELECTRIC COMMUNICATION WITH LIGHTSHIPS.

Several English lightships have been put in electrical communication with the shore, and valuable information has been transmitted with regard to ships in distress, many lives having been saved in consequence. There have, however, been several breakdowns of the apparatus, principally due to the chafing and breaking of the electric cable between the mooring and the vessel. As this is a contingency that it is difficult to avoid when the cable is led on board, a trial is to be made of the inductive system, in which the cable lies wholly on the bottom of the sea, and the signals are transmitted over the intervening space to the apparatus on board by electro-magnetic induction The apparatus to be used is the invention of M. Sidney Evershed, of Woodfield Works, Harrow-road, London, and its principle is illustrated diagrammatically in the annexed illustration taken from *Engineering*. Fig. 1, shows a lightship B, able to swing round a mushroom anchor. Around the circle which it is capable of occupying there is laid, on the sea bottom, a ring of cable A, connected to the shore station, as shown. A secondary coil is fixed on the ship, and should consist of, at least, 50 turns of insulated wire, of as low a resistance as possible. If the ship is built largely of iron, the secondary coil should be arranged around the outside of the bulwarks; its magnetic axis must be as nearly as possible normal to the plane of the ship's decks. Of course the coil must be as large as the dimensions of the vessel will permit.

Interrupted currents are sent through the submarine cable by means of a key K and a contact-breaker W driven at such a speed as to interrupt the current several thousand times a second. The discontinuous currents in the cable ring A produce rapidly alternating electromotive forces in the secondary coil, and alternate currents pass through the telephone T, and indicate their presence



FIGS. 1 AND 2.—METHOD OF COMMUNICATING WITH LIGHTSHIPS.

by the buzzing of its diaphragm. The signals are read by the Morse code.

The difficulty with inductive telegraphy lies in calling the attention of the operator, as, of course, he cannot live with the telephone at his ear. This difficulty appears to have been removed by Mr. Evershed in an exceedingly ingenious manner by the invention of a cumulative impulse relay. Several forms of the instrument have been worked out, one of them, on the principle of the D'Arsonval galvanometer, being illustrated in Fig. 2. A rectangle of wire V is clamped in an insulating support I. One side of the rectangle is placed between the poles N S of a powerful magnet, and when the rectangle is traversed by alternating currents, timed to correspond to its frequency of vibration, it receives a series of cumulative impulses, and is set in vibration. This vibration brings it against a contact on the similar rectangle P, which is tuned in unison with V. When the two touch the circuit of a local battery is closed, and a bell rung. The two similar rectangles are used to prevent accidental contact due to mechanical jars. The second rectangle may be traversed by alternating currents in the opposite direction to the first. The currents employed in calling are not the same as those for speaking. A frequency of 20 to 40 periods per second is suitable, and is obtained by means of a tuning fork or other similar device. The vessel on which the induction telegraph is to be tried in the first instance is the East Goodwin, which lies outside the Goodwins, and will require a cable of some 10 nautical miles in length.

YACHT STORAGE BATTERY LIGHTING.

Among the yachts on which the Chloride Accumulator has been installed for lighting purposes this season are the Linta, Sultana, Alcedo, Duquesne, Huntress, Washita, Vidette, Thespia.

NEWS AND NOTES.

THREE-PHASE TRANSMISSION AT BONDSVILLE, MASS.

As the advantages attendant upon the introduction of electricity into textile mills are being brought home to manufacturers by a study of the benefits already derived by other mills in which the electric motor has gained a stand, the number of plants is daily increasing. One of the latest converts to the new method is the Boston Duck Company of Bondsville, Mass., the mills of which are now operated partly by water and partly by steam. From the water they are able to derive about 600 H. P. over their present steam plant, consisting of two 250 H. P. engines; one being run condensing and furnishing power alone, the other non-condensing and being used partly for power and partly to furnish exhaust steam to the dye houses. The dye houses, however, require the exhaust steam from about only 100 H. P. Thus if the power were not required in the mill to help out the water wheels, the condensing engine could be shut down entirely and the other engine could be run at about half its capacity only.

Three thousand feet below the mills, this company own another water privilege on a difference in level of 22 feet. This was developed some years ago, and the company even went to the expense of building a foundation for a mill before they decided to give up the project. Since that time electricity has come upon the scene and the heretofore unutilized water power has now become of considerable value. Wheels are to be set up in the unused mill and 500 H. P. is to be transmitted back to the mills at present in operation at Bondsville. This will enable them to dispense almost entirely with their present steam plant.

The General Electric Company have undertaken to install the necessary electrical apparatus for this plant. It will consist of one three-phase 400 K. W. 900 volt generator and one synchronous motor of similar size, which will develop 485 H. P. on its pulley. The loss in the line has been calculated at about 3 per cent. only. In estimating the economy effected by the introduction of electricity, the Boston Duck Company have announced that they will not count the cost of the development of the second water power made in 1880, when calculating the operating expenses of the complete plant, as the money put out for the hydraulic improvements cannot be recovered and will not therefore be counted in as part of the present development.

WATER POWER AT UTICA, N. Y.

Mr. E. D. Matthews, of the Utica Highlands Co. and Syndicate, and the Trenton Falls Power and Electric Co. writes us that his company has control of a great water power, and allied enterprises, and that they would like to interest capital on favorable terms. Local capital is timid, not appreciating the extent to which water power plants are now being developed. According to Mr. Matthews, experts report that they have 14,000 H. P., at low water, at Trenton Falls, and that it could be easily and cheapily transmitted to Utica. The company holds for sale its power, and has control, it seems, of about 2,000 acres and 8 miles of gorge. Such power ought to find a ready and profitable market in Utica.

THE BRITTON PLAN FOR UTILIZING THE NIAGARA RIVER.

It is reported that William H. Britton, who is in the employ of Iribacker & Davis of Buffalo, is the inventor of a wheel or motor attached to a steel outrigger and submerged completely in a current of water. A motor like this with a 12-foot diameter and having 12 blades, submerged in a 12-mile-an-hour current (such as will be found in the gorge below the whirlpool, where it is proposed to locate them) will be expected to develop a power of from 160 to 200 horse-power. From the submerged current motor a shaft will connect with an overhead wheel, which in turn will be connected with the dynamo. The cost of each outrigger, with two wheels attached, will, it is estimated, come to from $5,000 to $6,000, and can be located every 12 feet anywhere in running water.

FIRST COMMERCIAL USE OF THE NIAGARA POWER.

A special dispatch from Niagara Falls of August 26 says:—At seven o'clock this morning the Niagara Falls Power Company first turned on the electric power generated by its dynamos and turbines from the torrent of Niagara River for actual commercial purposes. The current was transmitted to the works of the Pittsburgh Reduction Company, which a few moments later opened for business with a score of men. To-morrow morning forty men will be at work. The official beginning of the commercial enterprise was witnessed by the chief officials of the power company and affiliated concerns with great satisfaction. The current was generated by the second dynamo, and is estimated to have been about 2,000 horse-power.

SCOTCH WIND AND WATER IN WESTERN AUSTRALIA.

A special dispatch of Aug. 20 from Glasgow, Scotland, says:—An invention designed to provide motive power for the gold fields of western Australia has been patented by two gentlemen of this city. The invention contemplates the substitution of electricity and compressed air for the water power now in use. The Rothschilds and the government of western Australia have become interested in the patent, and a company will be formed with a capital larger than that of any stock company organized within the century.

HAWAIIAN CABLE.

The Hawaiian Government has granted a subsidy of $40,000 a year in aid of a telegraphic cable between the islands and the United States; and it is proposed to secure a similar subsidy from this country.

METALLIC LACTATES FOT ELECTRO-PLATING.

In connection with a paper on the electrolytic deposition, for analytical purposes, of metals dissolved as lactates or glycolates, Dr. Jordis, of Munich, pointed out that lactic acid provides an excellent solvent for electro-plating. As yet experiments have only been made in the laboratory with plates of 30 square inches surface. The deposits form so uniformly and easily, however, and adhere so well, that there is great hope for technical processes based upon Dr. Jordis' researches. The expensive free lactic acid is not required. In Germany lactic acid is quoted at 590 marks—about $145—per 100 kilograms (220 lbs.); a fairly pure acid can be obtained for 300 marks, while pure lactates of calcium and zinc, from which the acid is generally separated, cost 190 and 485 marks. Coatings of copper and brass of varying shades on iron, zinc, or copper, of zinc on iron and copper, and of iron and of nickel, can be obtained without difficulty, without any special apparatus. Whether the latter point will be confirmed in operations on a larger scale remains, of course, to be seen. As to zinc, Dr. Jordis does not appear to have been particularly successful. In any case, the process has great interest for engravers, whose blocks are not as a rule of large dimensions, and particularly for the silver-plating industry. Amalgamated brass is, in a bath of lactate of silver, covered with a pure white coating of silver, which takes the highest polish. It would be a great boon if we could replace the dangerous cyanide of potassium by the harmless lactic acid. The connection with milk might suggest bacteria, as the decomposition of the lactic acid into carbonic acid and acetal aldehyde need not, in the vat, proceed as certainly as it does in platinum dishes. But lactic acid is itself regarded as antiseptic, and the electric current, though perhaps not so fatal to micro-organisms as is often asserted, does not favor their development. The communication was brought before the second annual meeting of the German Electrochemical Society, which assembled at Frankfort-on-the-Main in the first week of June, under the presidency of Professor Ostwald.

THE INFLUENCE OF MOVING MATTER ON THE ETHER.

The problem of the motion of ether with or through ordinary matter has been again attacked by Herr L. Zehnder, who recently contributed an interesting paper on the subject to *Wiedemann's Annalen*. He endeavored to ascertain whether the ether is pushed along by atoms, or whether it passes through their substance without resistance, or, finally, whether only a portion of the ether adheres, and this portion only is carried along. Herr Zehnder's apparatus consisted of a cast-iron cylinder in which an air-tight piston moved. A small tube led out from one end of the cylinder, doubled back upon itself, and returned to the other end. Now, if the cylinder was exhausted of air, so as to leave nothing but ether behind, and the piston was then worked, the inference would be that the ether would stream through the small tube with a velocity as much above that of the piston as the ratio of the sectional area of the one to the other. The ratio was 560 to 1; and exhaustion was carried to the 40,000th part of an atmosphere. To ascertain whether the ether moved in the sense contemplated, a beam from a brilliant sodium flame was passed through two thick parallel glass plates; the second one being silvered at the back. This plate, by its two reflecting surfaces, split the beam of light into two, each part travelling through one portion of the small tube. Then the same beams were reflected back upon the thick plate, and returned along the way they had travelled, being finally reflected into the reading telescope by the first plate. Interference fringes were thus produced in the field of view, the motion of which would have indicated a movement of the ether; but no such motion was observed when the tubes were thoroughly exhausted, so that it was concluded that the ether passes through solid bodies. A similar negative result has been obtained by Dr. Oliver Lodge and others, in the efforts they have made to discover if there is any molecular drag on the ether.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED AUG. 27, 1895.

Accumulators:—

Secondary Battery, I. A. Timmis, London, Eng., 545,390. Filed Feb. 28, 1895.

An element for secondary batteries consisting of a thin sheet of metal corrugated in parallel uninterrupted continuous lines, and folded or plaited in continuous lines intersecting the corrugations.

Alarms and Signals:—

Electric Annunciator, G. J. Galbraith, Boston, Mass., 545,069. Filed Apl. 27, 1895.

Elevator Indicator, L. Malm, Cleveland, Ohio, 545,127. Filed Jan. 5, 1895.

Devices whereby a lamp can be made to glow at each successive movement of the finger and illuminate the index number on the dial of the floor indicator.

Fire Alarm Box, T. Walsh, Montreal, Can., 545.141. Filed Apl. 12, 1895.

An attachment in the form of an automatically operated grip or handcuff acting to detain the person operating the alarm until the arrival of the firemen.

Electric Signaling Device, W. Gillette, New York, 545,357. Filed July 5, 1894.

Details relating to a hotel telephone system.

Conductors, Conduits and Insulators:—

Electric Conduit, O. J. Kintner, New York, 545,296 Filed Mch. 16, 1893.

Means for maintaining a circulation of hot air through interior conduits to keep them dry and to ventilate the rooms.

Distribution:—

System of Electrical Distribution, T. A. Edison, Llewellyn Park, N. J., 545,495. Filed Dec. 6, 1886.

A system comprising high tension generators at the central station with rotary convertors reducing the potential at substations.

Dynamos and Motors:—

Means for Synchronizing Electric Motors, E. Thomson and E. W. Rice, Jr., Swampscott, Mass., 545,111. Filed March 8, 1893.

See page 000 this issue.

Commutator or Collector Brush, C. L. Coffin, Detroit, Mich., 545,347. Filed Feb. 5, 1895.

Consists of a strip of sheet metal comprising a solid non-perforated portion and perforated portions having a continuous edge.

Electrometallurgy:—

Process of and Apparatus for Refining Metals Electrolytically, W. H. Wiggin, Worcester, 545,328. Filed May 29, 1894.

The plates are constantly agitated in vertical planes.

Lamps and Appurtenances:—

Electric Arc Lamp, H. T. Harrison, London, Eng., 545,359. Filed Nov. 19. 1892.

Details of construction.

Miscellaneous:—

Hysteresis Compensator, B. Abdank-Abakanowicz, St. Maur, France, 545,042 Filed Mch. 17, 1893.

The method of correcting or neutralising the effect of hysteresis in electro-magnetic apparatus, which consists in employing in such apparatus a main and an auxiliary magnetic circuit and neutralising the effect of the residual magnetism of the first circuit by that of the second.

Thermostat, G. Hill, New Brunswick, N. J., 545,076. Filed Jan. 3. 1895.

Electric Gas Lighting Apparatus, J. W. Palmer, Nashua, N. H., 545,091. Filed Jan. 9, 1895.

Details of construction relating to the wiper.

Electro Magnetic Tool, C. F. Carpenter, Louisville, Ky., 545,149. Filed Aug. 20, 1894.

A percussion tool for cutting stone, metal, etc.

Means for Indicating Coincidence of Phase of Two Alternating or Polyphase Current Machines, J. H. F. Görges, Berlin, Germany, 545,282. Filed April 4, 1894.

An indicator for indicating when the separate currents generated by auxiliary coils correspond in potential, and a differential indicator for indicating when the said currents correspond in number of periods.

Electric Target, Milton T. Weston, Kenton, Ohio, 545,327. Filed Dec. 8, 1894.

Railways and Appliances:

Underground Electric Railway, D. F. Graham, Springfield, O., & W. P. Allen, Chicago, Ill., 545,070. Filed June 21, 1894.

A system which will permit of operation either by electrical energy or by the motive power transmitted through the means of a moving cable.

Trolley, J. L. Hanson, Omaha, Neb., 545,073. Filed June 4, 1895.

Insulated Support for Trolley Lines, F. X. Olcott, New York, W. J. Belcher, & F. C. Billings, Hartford, Conn., 545.151. Filed April 22, 1895.

Adapted to be assembled in the form of a straight line hanger or in the form of a pull-off, either double or single, for maintaining the alignment of a trolley line.

Electric Railway, J. C. Henry, Westfield, N. J., 545,158 Filed April 20, 1895.

A three wire system employing two generators of different potential and in which the motors are regulated without resistances of any kind.

Trolley Line Clamp, W. J. Belcher, Hartford, Conn., 545,187. Filed April 11, 1895.

Conduit Electric Railway, C. H. Johnson, San Jose, Cal., 545,204. Filed Feb. 23, 1894.

A rail conductor is supported on special insulators on which bears a trolley suspended from the trolley arm of special construction.

Underground Electric Railway, E. E. Moore, Chicago, Ill., 545,208. Filed Nov. 16, 1894

A double conduit placed between the tracks with special arrangement for drainage.

Trolley Controller for Electric Railways, L. W. P. Gray & P. G. Doescher, New Orleans, La., 545,358. Filed May 23, 1895.

Means whereby the trolley-staff or pole upon cars driven by electricity shall be prevented from flying upward in case it should jump from the main conductor; also to provide means whereby the motorman shall be able to control the current passing through the trolley into the car motor.

Guard and Guide for Electric Trolleys, J. R. Tristler, Westwood, O., 545,398. Filed June 1, 1895.

Electrically Operated Mine Car, H. B. Dierdorff, Columbus, Ohio, 545,404. Filed Dec. 24, 1889.

Details of construction.

Telephones:—

Telephone Holder and Cut-Out, A. F. Boardman, Somerville, Mass., 545,191. Filed Jan. 2, 1894.

A telephone switch operated manually by the insertion and withdrawal of the telephone receiver in and from a spring clamp.

Combined Telephone Receiver Support and Switch, G. F. Shaver, Yonkers, N. Y., 545,253. Filed Dec. 6, 1894.

The act of placing the receiver on its support throws a lever which makes the desired connections.

Telephone and Return-Call System, T. R. Brimner, Baltimore, Md., 545,402. Filed Aug. 16, 1894.

The object is to provide for establishing a telephone and return call between the office and rooms of a hotel without change in the wires of the annunciator instrument of those leading from the office to the rooms.

Telephone, G. F. Shaver, Yonkers, N. Y., 545,416. Filed June 8, 1895.

A system in which the connections of the signaling devices are not changed on taking down or putting up the receiver.

LEGAL NOTES.

A RED-HOT ASSOCIATED-UNITED PRESS LITIGATION.

As John R. Walsh of Chicago came ashore from the Teutonic last week, he was served with a complaint in a suit for $200,000, brought against him by the United Press for betrayal of trust and violation of his fiduciary obligations, while acting as Director and Treasurer of that corporation.

The complaint sets forth among other things that Walsh, while acting as Director and Treasurer, and having full knowledge of the business affairs of The United Press, secretly formed a purpose of despoiling and destroying The United Press for his own personal benefit and that of a rival organization, and how, to that end, he disclosed to Victor F. Lawson and Melville E. Stone, both executive officers of a rival corporation, the business secrets of The United Press, and exhibited to them statements in writing purporting to have been taken from the books of the plaintiff to show the financial condition of the corporation whose trusted Treasurer he, at that time, was, and made to them false and fraudulent representations that The United Press was in a state of panic and bankruptcy.

By these means and by various other misrepresentations and slanders, it is charged, Walsh was able to divert from The United Press, business to the amount of upward of $70,000 a year, included in this being the sums paid by the Chicago *Herald* and the Chicago *Post*, owned by John R. Walsh, and the Illinois *Staats-Zeitung*, controlled by him indirectly, its proprietor being under heavy financial obligations to him, and various other papers indirectly controlled or influenced by him, the details being plainly set forth in the complaint.

Having done this, the complaint declares, he, in February, 1894, demanded payment of a sum of money then owed to him by The United Press, and resigned his positions as Director and Treasurer of that corporation. When the money was promptly and fully paid, and The United Press driven into neither a condition of bankruptcy nor of panic, Walsh sought to withdraw his resignations in order that he might be once more in a position to obtain further information to use in hostility to the interests of The United Press, and for his own personal profit and aggrandizement, and it was not until May 15, 1895, that his final resignation was secured and accepted.

AN INTERESTING LAMP THEFT CASE IN NEW YORK CITY.

Last week, in New York city, Judge Jerome sentenced Thomas Jones, of 329 Stanton street, to six months' imprisonment, and Jeremiah O'Brien, of 402 10th street, and John Tracy, of 213 Lewis street, to four months each in the penitentiary, for endeavoring to steal lamps from the Edison Illuminating Company. It is the custom of the illuminating companies to give to their customers new lamps for those burned out, and on Friday afternoon, August 23, O'Brien and Tracy brought a large box of burned out lamps to the 26th street station of the Edison Company and, stating that they came from the Manhattan Club, asked to have them exchanged. As the Manhattan Club was not a customer of the Edison Company and, moreover, as a large part of the lamps were not Edison lamps, the request was refused. The men took the box to Broadway, where O'Brien was waiting with a truck, and while driving through Fourth avenue and the Bowery the three shied such lamps as were not Edison lamps at venders and passers-by, and in so doing hit one of the Edison employés who had been directed to follow the men. The Edison scouts who had been following them up, thinking that perhaps they would attempt to exchange the lamps at the Edison station in Duane street, notified the Superintendent there and when Tracy and O'Brien arrived they met with a cordial reception. The men there represented that they came from Childs' restaurant in Cortlandt street. The police were notified and arrested Jones who had remained outside the building awaiting developments, together with Tracy and O'Brien who had been detained in the building. One of the latter made a break for liberty, but ran into the arms of a stout employé who had been placed at the door in the event of such emergency.

As this is the first conviction for such an offence, it will be of interest to illuminating companies throughout the country.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

PROSPERITY OF THE BALL & WOOD CO.

THE Ball & Wood Co. of New York, reports that never in the history of its business has it had so many orders on its books as at present. This condition of affairs has compelled it to make not only a large addition to its works in building a new boiler house and re-arranging its steam plant, but also in the purchase of more large tools. Recent orders include engines for Milwaukee, Wis.; Terre Haute, Ind.; McGregor, Ia.; Helena, Mont.; Denver, Col.; Colorado Springs, Col.; New Orleans, La.; Altoona, Pa.; Wilkesbarre, Pa.; Flatbush, N. Y.; besides a large number for the new buildings now going up in New York City.

Both from its Chicago and New York offices, this Company reports some stiffening in prices, and altogether it is confident that the improvement of business will continue.

OKONITE CABLES.

The Okonite factory at Passaic is busy turning out two immense cables for the Metropolitan Telephone Company, to carry wires under the North River. Each of the cables has twenty-four conductors, and is over a mile long. The Okonite Company recently manufactured two similar cables to connect New York with Brooklyn. Another piece of work just finished is a cable three miles long and covered with lead armor, made all in one piece. It was shipped to Lenox, Mass., where it will be laid in a subway.

A BRUSH CONTRACT IN CANADA.

A special dispatch from Trenton, Ont., of Aug. 22, says: The contract for lighting the town for ten years has been awarded to the Brush Electric Company of Cleveland, Ohio, represented by Col. W. S. Rogers. The magnificent water-power, capable of producing 12,000 horse-power, north of town, on which a suitable power-house was constructed last year, will be used for the purpose. Besides an incandescent system of lighting, the company will develop the power by putting in large generators, and distribute the power through the town for manufacturing purposes.

ELECTRIC POWER IN SAN FRANCISCO.

THE San Francisco *Report* says that in that city during the past year over 600 users of power have given up other driving machinery in favor of the electric motor.

NEW ENGLAND NOTES.

SPRINGFIELD, MASS.—The Standard Telephone Company is making negotiations for the establishment of an exchange in this city. The New England branch of the Standard Telephone Company, known as the Eastern Standard Telephone Company, has headquarters in Boston, and is capitalized at $9,000,000.

THE BEACON LAMP CO. met with flattering success with their 11,000 lamps used in the Knights Templars' decorations. Mr. J. R. Masury, electrician of B. F. Keith's new theatre, reported that he used three makes of lamps in his Knights Templars' decorations, two-thirds of them were of the Beacon make, and in their four hour test they lost but one Beacon lamp, and 40 and 200 of the other makes respectively. The conditions under which they were used were very trying, owing to the intense heat due to close grouping of the lamps. The Beacon Lamp Company are justly proud of this result.

GINN & Co., the largest book publishers in New England, have recently decided the question of the isolated electric lighting plant for their new building at Cambridgeport, Mass. They have given up the idea of attaching motors directly to the various presses, and their power equipment will consist of a slow speed engine for the main building, and a direct connected engine and dynamo plant for furnishing about 1,000 incandescent lights. After carefully considering the various types of apparatus on the market, they have placed their order for a direct connected engine and dynamo plant, consisting of a Siemens & Halske slow speed dynamo, and a Woodbury automatic high speed engine. It is their intention to have one of the finest plants in New England.

COLUMBIA, S. C.—A party of leading citizens of Athens, Ga., have been inspecting the electric power transmission in the cotton mills at Columbia, and will now put in at Athens, it is said, an electric mill of 10,000 spindles. The leader of the party was Capt. J. J. C. McMahan.

NEW YORK NOTES.

MR. THURLOW WEED BARNES, of the Standard Telephone Co., is understood to announce that his company proposes to do only long distance work.

ALTOONA, PA.—Mr. E. B. Green, the energetic superintendent of the Edison local company is going in this year for electric heating, and hopes to work up a good load for his new plant.

THE CHESLEY ELECTRIC CO., W. S. Chesley, general manager, &c., 601-5 Newark street, Hoboken, have closed a contract with the American Sugar Refining Co. to rebuild three 30 K. W. Edison dynamos that have been in a fire. Business is quite brisk and the working force has been increased.

BROOKLYN, N. Y.—There has been filed the certificate of incorporation of the Union District Messenger company. The company is a somewhat novel one, and its operation is to be confined to the limits of the Twenty-sixth ward, the residents there to be in charge. It is proposed to construct and operate telegraph lines there. The incorporators are Simon C. Ostrom, Henry Kohlert, Thomas F. Livingston, Emanuel Newman, Joseph K. Clark, Richard J. Kelly and Louis L. Hoop. The new company has a capital of $12,000.

WESTERN NOTES.

ROCHESTER, MINN.—The telephone exchange which has been put in this city by Messrs. F. S. Haines and J. A. Melone is being put in operation.

BARABOO, WIS.—All the stock for the proposed telephone exchange in this city has been floated, and the system will be put in at once. Frank Bell has the contract, and the Standard telephone will be used.

ST. PAUL, MINN.—Articles of incorporation of the American Signal and Power company, of Minneapolis, have been filed. Capital stock, $100,000; limit of indebtedness, $50,000. The business of the corporation will be the furnishing of electrical supplies.

DETROIT, MICH.—The directors of the Harrison Telephone Co. have elected as president, Albert Pack; first vice-president, Charles Flowers; second vice-president, R. A. Brett; third vice-president, C. P. Collins; treasurer, Collins B. Hubbard; secretary, W. L. Holmes.

THE ELECTRIC STORAGE BATTERY CO. has opened a branch office at 309 Dearborn street, Chicago, in charge of Mr. C. W. Woodward, well known in storage battery work. A large number of Chicago plants are now utilizing Chloride accumulators, including those of the Chicago University, Chicago Telephone Co., Western Electric Co., &c. The firm of Pierce & Richardson will be connected with this branch in the capacity of consulting engineers.

COLUMBUS, O.—The Interstate Telegraph and Telephone Company, of Columbus, has been incorporated by P. J. McCaffrey, George S. Thompson, Charles J. Ewin, Thomas Thompson and Matthew A. McGrath. The object is said in the articles of incorporation to be to construct, own and operate telegraph and telephone lines in the states of Ohio, West Virginia and Kentucky, and doing a general telephone business with offices in Columbus, Cincinnati and Bellaire, and having these cities as termini of the main lines. The main lines will pass through the counties of Franklin, Pickaway, Madison, Fayette, Clinton, Warren, Clermont, Hamilton, Licking, Muskingum, Guernsey and Belmont. The capital is $10,000.

FINANCIAL.

HOOSICK FALLS, N. Y.—The financial showing of the Hoosick electric line for the past year has been exceedingly good. The total receipts from July 13, 1894, to July 13, 1895, were $13,026.62. The total number of passengers was 270,888, which does not include children under five years of age.

TROY, N. Y.—The Troy City Railway in the year ending June 30, had gross earnings $454,078, and after paying $101,774 interest on bonds had $105,000 left to pay out in dividends. The operating cost including taxes was only 58 per cent. 8,652,722 passengers were carried by 128 motor cars and 48 horse cars, on 31 miles of track.

☞ Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.

THE
Electrical Engineer.

Vol. XX. SEPTEMBER 11, 1895. No. 384.

ELECTRIFYING ZION:—THE BIG COTTONWOOD POWER TRANSMISSION, SALT LAKE CITY, UTAH.

BY

George Heli Guy

I.

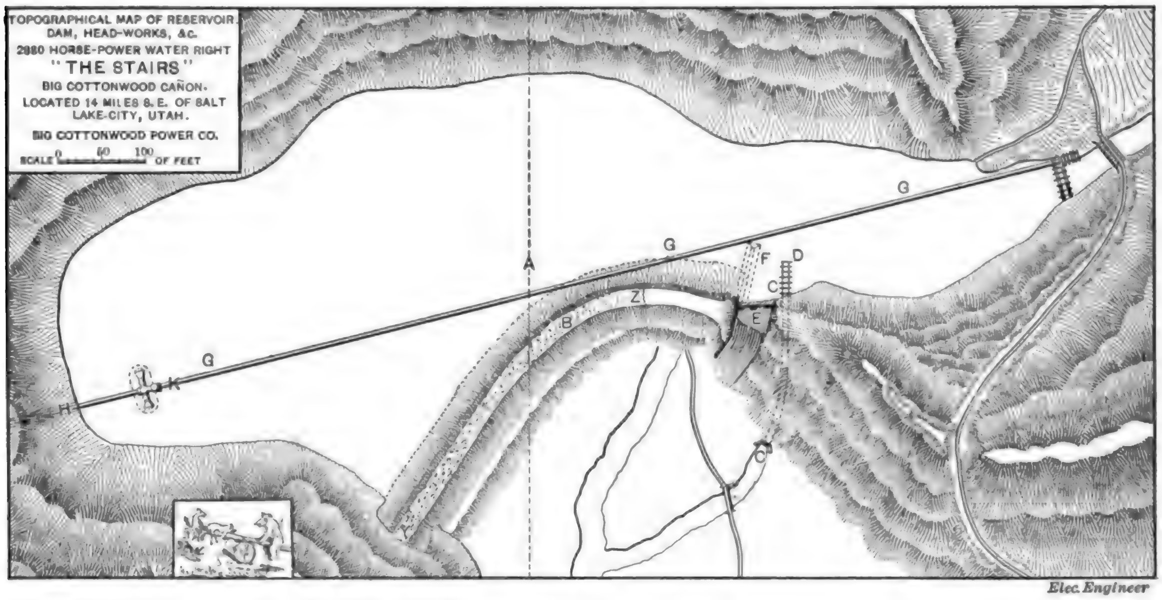
B. M. Jones

A KEEN and travelled observer, who puts the longitudinal limits of his wanderings at Turkey in the East and Utah in the West—from Moslem to Mormon—says a visit to Salt Lake City convinced him that from a sociological standpoint the followers of the Prophet Smith are more interesting as a study than the followers of the Prophet Mahomet. One needs to see the capital of the Church of Jesus Christ of Latter Day Saints, with its great ten-acre blocks, its broad, rectangular streets, its mountain water system, its quaint Mormon walls, temple and tabernacle, to appreciate the marvel of the Mormon exodus of 1846, and the stupendous works of the wondrous chief and builder, Brigham Young. The lever which became such a mighty power in the hands of this great natural leader of men is now discarded, but the work remains. Brigham Young practiced and advocated plural marriages because he wanted his colony to increase. To him it meant fructification and rapid colonization. But polygamy is now dead in Utah, and the people have faced toward a new life. Confident in the strength of its honesty of purpose and its splendid half-century record of privation, patient industry, prosperity, culture and wealth, the great Mormon colony of the West is seeking touch with the rest of mankind, and expanding into wider sympathy with the outside world. Gentiles are now welcomed into the best Mormon social circles. The community on every hand shows signs of vigor and success, socially, politically, and financially. Since the abandonment of polygamy, the membership of the church has increased amazingly, and its missionaries in all corners of the globe tell of the rapid accession of converts that is being brought about by the removal of the primary cause of outside hostility. In the West alone, there are 400,000 communicants of the Church of the Latter Day Saints. The territory of Utah is to be raised to Statehood, and its material wealth is seen in the number and magnitude of its home industries. But its career is only just begun. It has within itself a fund of resources that will bring it into a leading place among the forces of the age, and it is to the development of these agencies that it is now bending itself. The sublime Wahsatch range, under the shadow of which Salt Lake City springs out of the plain, is studded thickly with water streams, caves, and pockets, fed by the springs and drainage of the mountain, the overflow from which has always been utilized by the Mormons for the fertilization of their valley farms. The grandeur and beauty of its peaks and lakes are unequalled even in the Bernese Alps, and the picture of Lake Blanche, with its setting of snow-mantled cliff, shown on this page, will suggest to the traveller in Central Europe the rugged and awful profile of the Matterhorn. This and seven other of the Wahsatch lakes, lying still, dark, and solemn, at altitudes of 11,000 to 13,000 feet, are now to be the means of filling the valley below with light and gladness. In the picturesque Big Cottonwood Canon, where the granite blocks for the ponderous and imposing Mormon temple were quarried, these waters are being dammed, and converted into a power that will develop the resources of Utah in mines, products, and manufactures, to an extent almost unparalleled in the history of the West. The Big Cottonwood Power Company has practically completed its plans for the generation and transmission of electric power from the various water supplies in the Big Cottonwood Canon, thirteen miles south-east of Salt Lake City, for the supply of light and power within the limits of the city, and to the factories and small towns in the vicinity.

LAKE BLANCHE: ONE OF THE FEEDERS OF THE BIG COTTONWOOD WATER POWER.

II.

The power station is located in the Cañon, at "The Stairs," 14 miles by pole line from the distributing station of the Salt Lake & Ogden Gas and Electric Light Company, in Salt Lake City. At this station, there is a minimum flow of 3,400 cubic feet of water per minute, which,



TOPOGRAPHICAL MAP OF RESERVOIR, DAM, HEAD-WORKS, ETC., "THE STAIRS," BIG COTTONWOOD POWER CO.

working under 380 feet head, produces 2,447 H. P. any and every hour in the year. During nine months of each year, it will give nearly 4,000 H. P. The storage reservoir at the head of "The Stairs," has an available capacity of 24 hours' continuous flow of the stream, making all of the water available by using an excess during maximum loads and allowing the reservoir to accumulate during minimum loads. 58,800 H. P. hours per day of 24 hours, is looked for from this source, of which 68 per cent. can be delivered in Salt Lake City in contract form, making 40,000 H. P. hours net daily. The 68 per cent. efficiency is derived from: Pelton water wheels 80 per cent., G. E. generators, 94 per cent., G. E. transformers (raising) 97½ per cent., line transmission 95 per cent., G. E. transformers (reducing) 97½ per cent., or a total of 68½ per cent. The map of the reservoir shows a pipe line extending from the head gates, submerged in the bottom of the reservoir, to a penstock or receiver wood housing with "grizzlies" located just below the bridge. This pipe, of steel-banded redwood, is anchored to the bottom by rock piles, and is to be used in the event of its being necessary to drain the reservoir, without interfering with the running of the station. This is accomplished by closing the head-gate valves, and opening the reservoir valves in the drainage tunnel, and the station will thus be supplied from the natural flow of the stream, during such time as the reservoir might be empty.

III.

The outside dimensions of the generating station are 34 feet by 100 feet. The generating plant consists of four 450 K. W. three-phase General Electric generators, separately excited, non-compounded, set with armatures, parallel to each other, facing up in true line in the building as shown in plan and elevation on page 248. Each generator is driven by one heavy special Pelton wheel, 60 inches in diameter, provided with two nozzles 3¼ inch diameter. The straight nozzles are provided with a gate valve for shutting off, and the lower nozzle is equipped with a hood regulator, so that both good regulation and economical use of water are secured. Each nozzle at 370 feet effective head, produces 310 mechanical H. P., and runs at 300 revolutions per minute, its economical speed. The water wheel is keyed directly on the armature shaft, in lieu of a pulley. In addition to the generators named, four 12½ K. W. exciters, made up in two sets, will be used; both generators of each set being connected together by friction couplings, and each generator to be driven by a 14-inch Pelton wheel, with cast housings. Each set will consist of two generators, and two wheels will be built up on a cast-iron base-plate, making a rigid and direct connection. This application provides exciting energy in two units, and at all times either one or two exciters are in reserve. The exciters are to be run in multiple, and all connected to one common "bus line" on the switch-board. The three-phase generators will also be operated in parallel. There will be six raising transformers, 265 K. W. each.

IV.

The poles for the line construction were selected from live growth of Sand Point (Idaho) cedar. The smallest are 40 feet long, and 8 inches in diameter at the top. They are placed 100 feet apart. The line conductors consist of 12 wires, four circuits of three wires each; all No. 2, soft-drawn bare copper, and connected to the same common "bus line," at the generating and at the distributing station. The line loss, in delivering 1,520 kilowatts at 10,000 volts, will be something less than 5 per cent.

The transmission line from generating to distributing station is 14 miles by pole line. The distributing station is owned by the Salt Lake & Ogden Gas & Electric Light Company, who rent it to the Big Cottonwood Power Company at a nominal rent. It contains, for "step-down" transformation, nine 175 K. W. air blast transformers, from the secondary side of which the Electric Light Co. buys the current wholesale by meter. This arrangement is a most convenient one for both companies. The actual terms of the contract are that the electric light company is to be supplied with all the current it can dispose of for electric lighting and power, in units of 10 H. P., and under, the Big Cottonwood Company reserving the right to supply power to motors in units exceeding 10 H. P., and the right to reach such wholesale users of power by wires erected on the electric light company's poles, throughout all the districts within the city limits. The contract begins January 1, 1896, and runs for a term of five years. Its conditions are that the current is bought at 2,000 volts, three-phase, at a stipulated price per K. W. hour, which will be used to supply electric light and power for any purpose up to 10 H. P., and for elevator service up to any limit desired by the lessees. 2,000,000 units annually is the minimum limit of the consumption of current.

The present production of the electric light company is practically 3,000,000 units per annum by the use of coal after the usual central station methods, and the contract provides that as soon as the transmission power plant is

in operation, the steam plant of the electric light company is to be abandoned, the price to customers reduced, and other changes made that will be to the advantage not only of both companies but also to that of the public, by promoting the production of cheap electric power.

V.

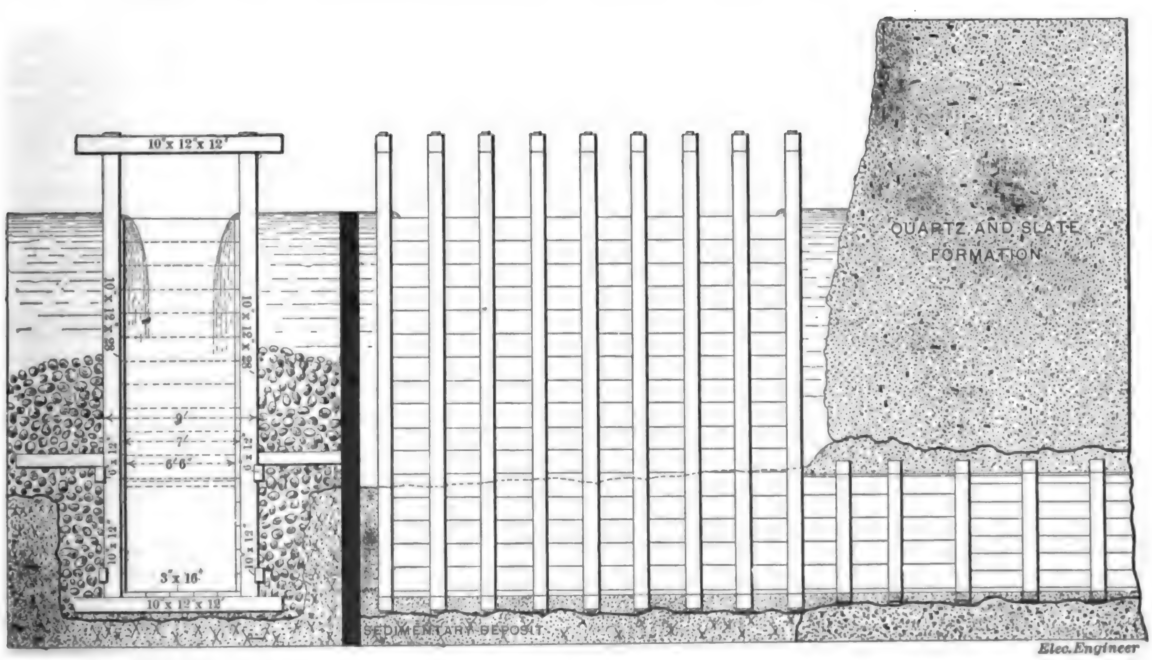
The final cost of the complete development is estimated at $300,000. An estimate of $300,000 for the original outlay for "The Stairs," would give for construction expenses—at 2,258 H. P.—$132.72 per net H. P. delivered in the city ready for use. The future of the company seems to be well assured. The company's affairs have been so well administered that much more than half the power to be developed has already been disposed of absolutely, and the guaranteed total revenue from completed contracts is over $100,000 annually. Although the company is confining its operations for the present to "The Stairs" supply, it has other valuable water rights partly developed by means of which it could at any time largely supplement its output.

VI.

It is worth while here to review briefly the natural advantages of Salt Lake City, which must be borne in mind if anything like an adequate idea of the importance and far-reaching effects of this great semi-Mormon enterprise is to be arrived at. Cheap electrical power will open up possibilities for electro-chemical work, such as the manufacture of aluminum. The district has bauxite in abundance, and in this industry power is all-important, and freight is hardly considered. For the manufacture of salt products, bleaching powder, disinfectants, soda, sodium, calcium carbide, &c., all the raw materials are on the ground, and cheap power only is needed. The electro-deposition of copper will certainly grow into a huge industry, for the extensive leads of copper ores are as yet undeveloped. A large copper smelting plant is now about ready to start. The electro-deposition of gold and silver is also a coming industry which will rapidly expand when cheap current increases the economy of the process. These are classes of work depending for their successful prosecution almost entirely on power, and requiring materials mined or found in the Salt Lake country in enormous abundance. In mills and factories the ordinary industrial operations likely to be created by cheap power are wool scouring, paper making, the manufacture of cotton fabrics and the making of flour. With the increase in these factories there will be a call for better facilities for iron workers and engineering work, which will require further power. There will be a prompt and large demand for current for electric transit. Cheap power will enable trolley lines to be pushed out all over the Salt Lake Valley, to be used for bringing farm produce into the city and ores to the smelters. With these improved facilities for transportation, the farming industry of the Salt Lake Valley will increase enormously, and a large fruit trade will be established. Two electric roads are already operating successfully; the Salt Lake City Railroad, with about 70 miles of track, and 45 cars, and the Rapid Transit Company, with about 28 miles of road and 24 cars. These roads already stretch out from 5 to 10 miles from the centre of the city. The output of gold and silver ore with lead bases is infinitely larger than statistics show, owing to the fact that enormous quantities of ore are shipped to Colorado smelters. Before long these ores will be smelted in Utah by electrical processes. The headquarters of the large mines, such as the Ontario, Centennial Eureka, Mammoth, Anchor, Crescent, Silver King, and the various mines in Park City, Tieutic, Bingham and Mercur, are all located in Salt Lake City. The first successful practical application of the cyanide process for extracting gold ores was made at the Mercur mines, located within 10 miles of the city. There are four large smelters and five sampling works. These smelters and the mines require large quantities of power continuously through the year, and though the application of electricity to mining is somewhat slow, it will surely become general. The Ontario mine has taken the lead by putting in a small monocyclic light and power plant, utilizing the waters from the great drain tunnel.

VII.

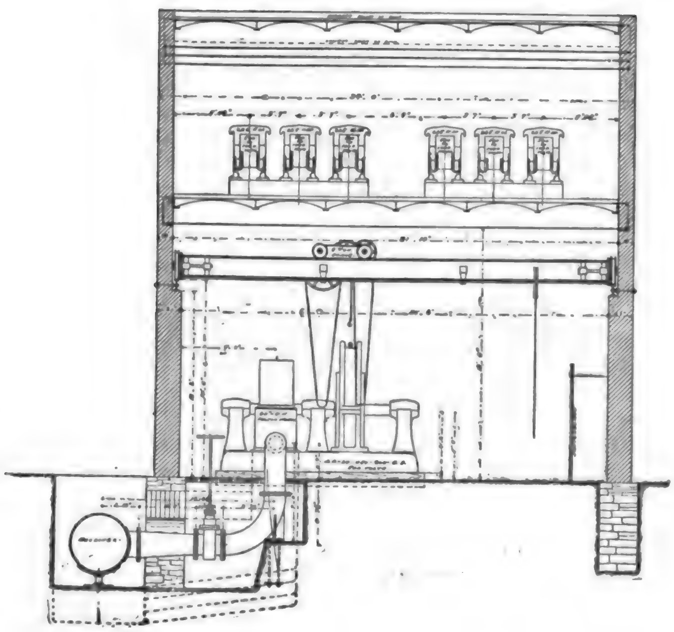
This is only a partial list of the commercial possibilities which will be opened up by the new conditions. But the Big Cottonwood transmission is remarkable not only for the immense development of which it will be the incentive, but as affording at its distributing station, an instructive illustration of supreme ingenuity in grafting new methods on to old appliances, and in combining the best points of more or less antiquated, and of modern practice in a harmonious and highly effective system of electrical distribution. It is fortunate that this critical work has fallen into such hands as those of R. F. Hayward, the able general manager of the Salt Lake & Ogden Gas & Electric Light



OVERFLOW HEADGATE AND TUNNEL FLUME, AT "THE STAIRS," BIG COTTONWOOD POWER CO.

Company, whose deservedly high reputation as an electrical engineer extends far beyond the limits of the State in which he has so successfully labored and into foreign countries.

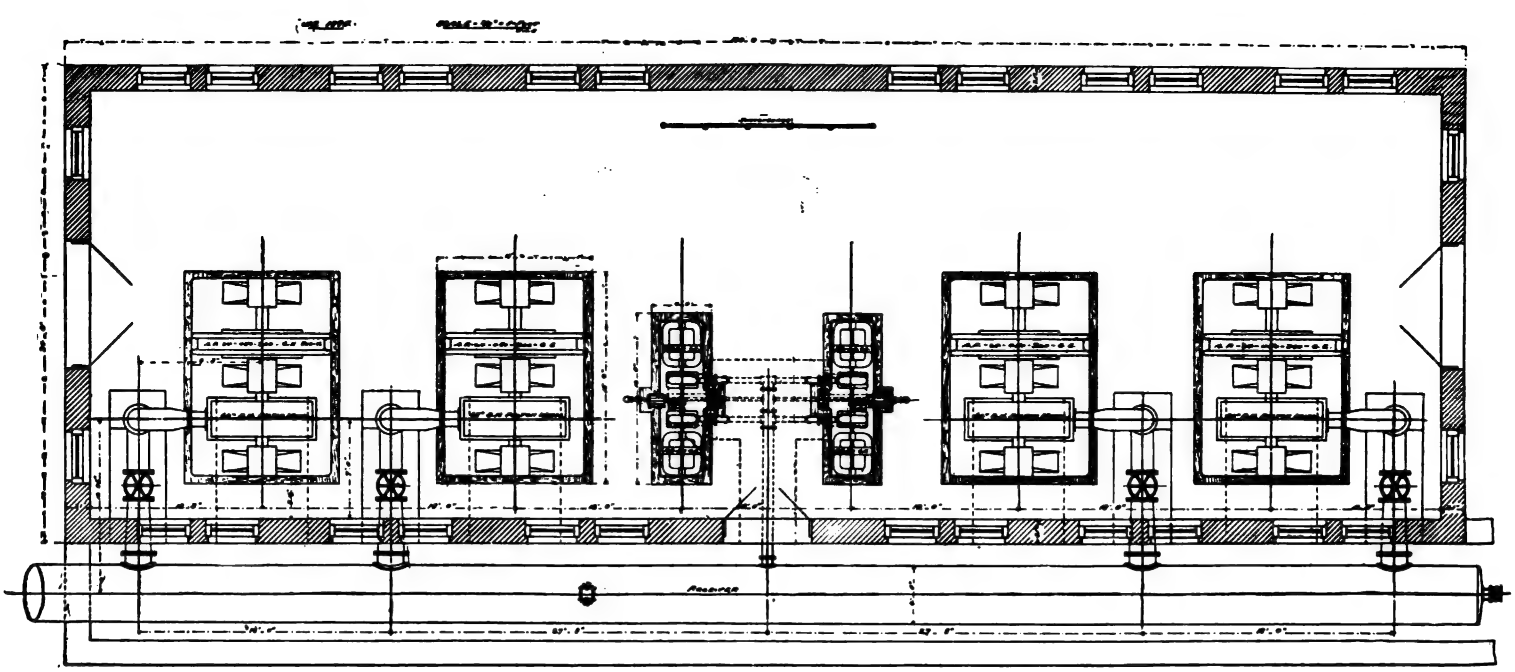
The new system, when complete, will consist of a net-



POWER HOUSE OF THE BIG COTTONWOOD POWER CO.—TRANSVERSE SECTION.

work of primary mains with a network of low tension secondaries, wherever the houses are in close proximity to each other. The primary mains will be at 2,000 volts. They will run along every street east and west and will have equalizing cross mains on several streets running plated. The transformers will be placed at street intersections in banks either fixed on the poles or in any suitable location near the intersection. In the commercial districts there will be a bank of transformers at every street intersection; but in the incidental districts one bank will be placed at every other intersection, the blocks being 792 feet square. Arrangements will be made for switching out alternate banks of transformers during light loads to save the waste of energy. To do this both the primaries and secondaries of the transformers will have to be controlled. The feeders will be brought from a distributing station situated near the centre of the town. The current will be supplied from the generators of the Big Cottonwood Power Company's station on the three-phase system. The feeders and primary mains will therefore consist of three wires each of the same size. The secondary mains will consist of three wires and a neutral wire. The voltage between any one of the three wires and the neutral will be 115, and this will be the voltage of the lamps. Motors, synchronous or non-synchronous, can be connected at any point to the secondary mains, or, when the motor is large, separate transformers will be used. It is intended to eventually use the alternating current for all arc lamps, in which case they will be connected to the secondary mains with small transformers. For street lighting it will be necessary to make special arrangements for switching the lamps on and off. At present there is a mixture of all kinds of systems in the station, but when the new system is complete, instead of the multitude of heterogeneous wires and circuits now existing, there will be three 2,000 volt primary wires and four secondaries on each street running east and west, and only four secondaries on streets running north and south.

The distributing station will be a substantial fireproof building, with a room for the 10,000 volt step-down transformers, a room for the 2,000 volt switchboard, and a room fitted up with instruments for testing and calibrating meters, etc. The current will be brought from the step-



POWER HOUSE OF THE BIG COTTONWOOD POWER CO.—PLAN.

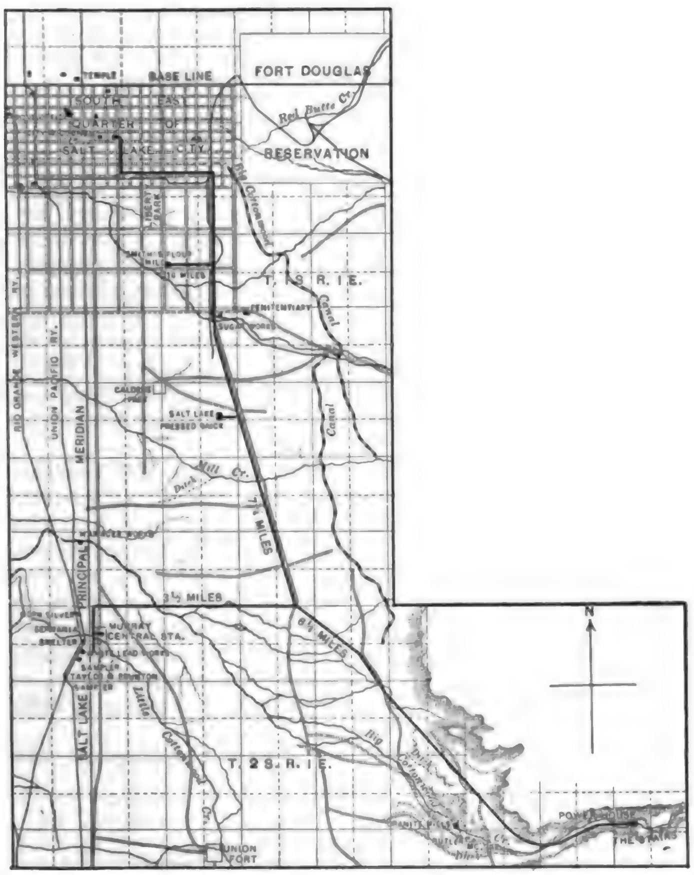
north and south. There will eventually be ten feeding points, though at first only six will be required. The secondary mains will be used almost entirely; only when the houses are very scattered will separate house transformers be used. In the commercial district, the secondary and primary mains will eventually be put underground, though this is not immediately contem-

down transformer to the distributing board. On the first panel will be a three-phase Thomson wattmeter for recording the energy received; also three amperemeters, one in each leg of the system, to show the balance; also, a station voltmeter to show the volts on the secondary wires at the feeder points, for which purpose, pilot wires will be put up. From the ammeter the current will pass along three

bus bars to the several three pole switches, from whence it will pass through fuses to the feeders. The feeder switches are designed for 100 K. W. each. Only ten feeders will be at first arranged for, though more will be added as they are required.

The distributing system and feeders have been designed of ample capacity for a very small drop, and with the complete system of primary and secondary mains the regulation will be very perfect. By cutting out transformers during times of light load, it is expected to obtain a very high distribution efficiency.

The change from the old to the new system will be no easy matter, and will have to be done gradually. In order to take the initial steps immediately three 150 kilowatt three-phase alternators (General Electric) will be driven by the existing steam engines, and will supply energy in the commercial district until the Cottonwood plant is



Map Showing Location of Power Line.

ready. When the Cottonwood supply is established, these generators will be used as synchronous motors to drive the arc lighting machinery, and when the direct current arc lamps are replaced by alternate current lamps the machines will be available for use as motors whenever required. It is contemplated to use presently the old single-phase alternators as motors. In this way much of the old plant can still be utilized.

VIII.

The Big Cottonwood is thus to take its place among the great power transmissions of the country. With it will always be inseparably connected the name of Robert M. Jones, who planned the scheme and piloted it to success with characteristic skill and tenacity. Mr. Jones is a distinct figure in the history of electrical work in the West. He was born in Ashtabula Co., Ohio, in 1853. In 1870 he joined a camp engaged in government surveys in Indian territory. After two years he obtained the position of U. S. Deputy Surveyor, and in that capacity was closely identified with civil and mining engineering through New Mexico, Arizona, Colorado, Wyoming and Utah, until 1884, as he describes it: "A dismal siege of fourteen years; most of the time in advance of civilization, soap and railroads." During this period at intervals he had the supervision and handling of mining and milling machinery, and held the post of Master Mechanic of the Quartermaster's Department, of the District of New Mexico and Arizona for two winters. In 1880 he brought out a "solar transit," combining the meridian-giving qualities of the Burt solar compass, with the accuracy of the engineer's transit. Up to 1885 the electrical industry in the Intermountain region was confined to telegraph and limited telephone work. In electric lighting there were only three small Brush stations, at Denver, Cheyenne and Salt Lake City, respectively. Mr. Jones took a prominent part in the organization of the Laramie (Wyoming) Electric Light Company, conducting the business as secretary and manager, and planning and superintending the mechanical construction of the station, which was equipped with Edison apparatus. At this time the Laramie station was rated the seventh as to capacity in the United States, and for three years of Mr. Jones's management it was the second as to dividends. Mr. Jones was the first to recognize the value of the Sprague direct current motor for Western work, and he installed three of the first motors made—25 H. P.—for driving a 100 barrel capacity flour mill in Laramie. The installation worked without a hitch. It was at the time noted in the East as a matter for surprise that the very earliest applications of electrical transmission of power could be made in such an out-of-the-way country as Wyoming. In May, 1889, Mr. Jones began the construction, under private contract, of the electrical equipment of the Salt Lake City Railway with Sprague apparatus, and he has since been associated with practically all the important electrical installations in Utah and Wyoming. In point of fact, he holds a record of over 90 per cent. of the entire electrical work done in those territories. Since 1886 Mr. Jones has been actively engaged in the engineering development of the Big Cottonwood transmission which is now regarded as the third installation in the country in point of the power developed and the importance of its commercial bearing.

WHAT HINDERS TRANSMISSION AT 50,000 VOLTS?

BY EDW. P. BURCH,

Electrical Engineer, Twin City Rapid Transit Co.

In The Electrical Engineer of Aug. 21, p. 186, I note in a description of the line to be used in the transmission near Fresno, Cal., of some 7,000 H. P. at 11,000 volts, the writer states that "thirty miles of the route are through an open level country under ideal conditions of transmission."

In one of our stations we often use two 100-light arc machines in series and have in regular service an "Excelsior" dynamo, which supplies current to 151, T.-H., 10.5 ampere, 50 volt lamps, on a 21 mile circuit, most of the lamps being at shops and at a lake six miles from the machine. The circuit runs through the city, and then along boulevards where hundreds of trees rub against the K. K. wire which has been in service five years. Green glass insulators and common 30 foot poles are used.

The line insulation during the past year has averaged one million ohms to ground, and almost as high between legs. The minimum insulation after long soaking rains seldom goes to 100,000 ohms between legs or to ground, and during some very wet weather often remains as high as one million ohms. The leakage is distributed and we have no trouble; the machines run for months without "slopping over;" 7,000 volts potential between legs is common, and this during wet weather,—we often run higher. Had we men to keep our circuits always clean,

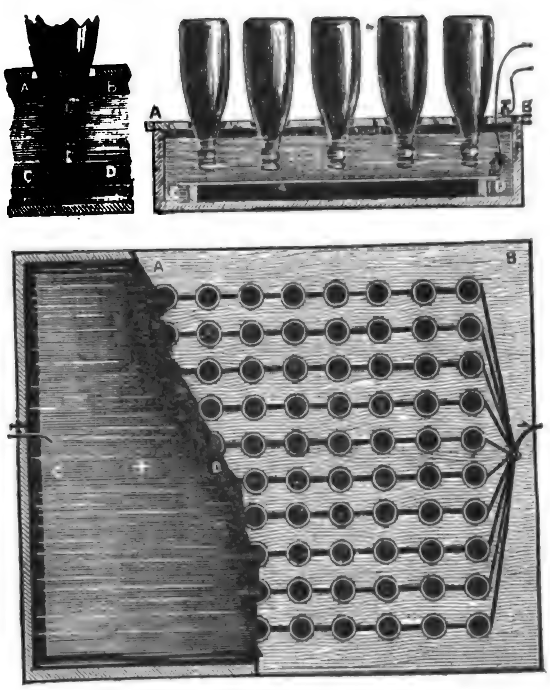
with good insulators and no trees, it seems as if we could easily stay at ten million ohms insulation resistance (which is what we now average during the winter).

The point I am coming to is, what is hindering power transmission engineers from using, say, 50,000 volts pressure. If transformers are in series the strain is distributed and danger to life and apparatus is small. The line will certainly be all right. Who will state why higher potentials are not used when general economy calls for it?

MINNEAPOLIS, MINN.

SEALING CHAMPAGNE BOTTLES ELECTRICALLY.

In a recent number of *La Nature*, Mr. A. M. Villon describes a novel method of sealing champagne bottles. The loss and deterioration of champagne due to the escape of gas has long made some process of perfect air-tight sealing desirable. M. Villon accomplishes this by covering the cork and a part of the neck with a thin layer of copper electrically deposited. For this purpose the neck of the bottle is covered with a conducting substance such as black lead, zinc or copper powder, and plunged in a galvanic bath, as shown in the accompanying illustration.



SEALING CHAMPAGNE BOTTLES ELECTRICALLY.

This bath has a cover of paraffine wood, A B, with conical holes, which are lined with copper rings. All these rings are connected among themselves, and with the negative pole of the dynamo; while a copper sheet in the bath is connected to the positive pole. The bottles are simply inserted in the holes, neck down, and when a layer of $\frac{2}{10}$ to $\frac{3}{10}$ of a millimetre has been deposited the current is stopped. The deposit may be gilt, silvered or given any desired shade in special baths. The process of course can be employed to seal bottles for mineral waters, preserves and a variety of products.

ABDANK'S HYSTERESIS COMPENSATOR.

The researches of Ewing, Hopkinson and others have shown how greatly the action of iron depends upon its previous magnetic history, and hence when iron masses are employed in electrical indicating and other apparatus these effects of residual magnetism, coming under the more general class of hysteresis phenomena, introduce errors. As a result, indicating instruments of this type have been shunned in the past where accuracy was considered desirable. The simplicity and cheapness of this type of instruments has nevertheless given them considerable vogue, and the most recent attempt to remove the cause of objection to their use will therefore be of interest.

M. B. Abdank-Abakanowicz, of Paris, well known to many American electricians, has just devised what he calls

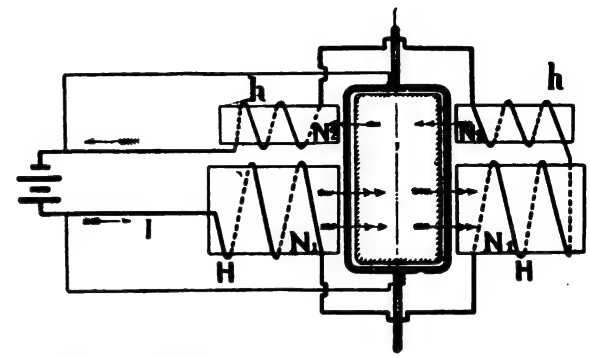


FIG. 1.—ABDANK'S HYSTERESIS COMPENSATOR.

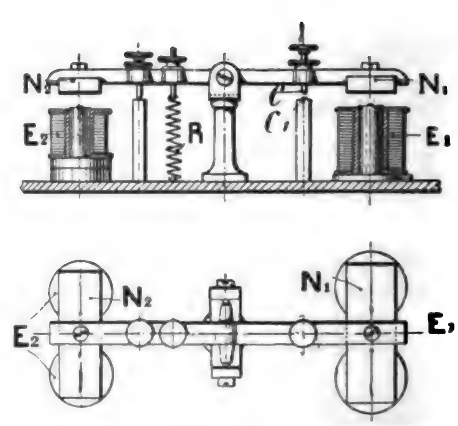
a hysteresis-compensator, to effect the desired purpose. This he accomplishes by combining with a magnetic circuit one or more masses of iron or steel, constituting what he calls a "secondary differential magnetic circuit," the action of the lines of force of the secondary circuit being opposed to those of the principal circuit. By properly choosing the dimensions of the secondary, with reference to those of the principal magnetic circuit, a differential value may be obtained for all currents within the range of the apparatus, which will be proportional to those currents. In other words, the effect of the residual magnetism of the first circuit is neutralized by the residual magnetism of the second.

The accompanying diagram Fig. 1 shows the application of these principles to a continuous current wattmeter. The potential is measured by the movable coil and the current is made to traverse the coils H, of the principal electromagnet and the coils *h* of the secondary or compensating electromagnet. The core N′, which produces the principal flux, is made of metal having the smallest amount of hysteresis possible, of soft iron, for instance, while N², which produces the flux for compensation, is made of cast iron or steel, or some metal having a high coefficient of hysteresis.

The double arrows in the diagram represent the



FIGS. 2 AND 3.—ABDANK'S HYSTERESIS COMPENSATOR.

directions of the magnetic fluxes and the single arrows those of the current. By varying the sections of the two cores N′ N² the ampere-turns applied to these cores and the air-spaces of the magnetic circuits, it is possible to make a combination such that the residual magnetism is either entirely or only in part compensated, and that the

resultant magnetic flux will be always proportional to the current, in which case the resultant torque of the armature will be proportional to the watts. Practically the same method may be applied to the case of a solenoid acting on a core of soft iron, which core it is desired shall be drawn in by the action of the solenoid to a certain predetermined point when the current shall have attained a certain predetermined value.

Figs. 2 and 3 show the same principle applied to a relay. The principal electromagnet E′ acts on the soft iron armature N′ in opposition to the spring R and against the action of the differential electromagnet E² and the armature N², which have a high coefficient of hysteresis. The two electromagnets are supposed to be excited by the same current. By choosing suitably the elements of the magnetic circuits of the two electromagnets it is easy to arrive at such a combination as will insure that the contact between *c c′* will always just take place when the current has attained a certain predetermined value, whatever may have been the previous values of the current. The practical rule to follow in this case is as follows: The attraction due to the residual magnetism of the electromagnet E² and of the armature N² ought to be equal to the attraction produced by the residual magnetism of the electromagnet E′ and of the armature N′ for the position of contact.

ELECTRIC TRANSPORTATION DEPARTMENT.

OPERATING ELECTRIC AND STEAM ROADS ON THE SAME TRACK, LOUISVILLE, KY.

The accompanying engravings show views taken from photographs on the railway of the Kentucky & Indiana Bridge Co., extending between Louisville, Ky., and New Albany, Ind., over the cantilever bridge across the Ohio River. This railway is of peculiar interest, as it is the only one in the world, so far as our information extends, over which steam and electric trains are regularly operated on the same tracks. In view of the increasing tendency toward the use of electric motors for suburban passenger service, and the desire to retain steam locomotives in use for freight service and perhaps for heavy express service on the same lines, the experience upon this short line of railway is of especial interest.

In an interesting letter appearing in our excellent contemporary, *The Engineering News*, Mr. Geo. MacLeod, superintendent of the Kentucky & Indiana Bridge Co., describes the salient features of this road as follows:

Prior to August 25, 1893, the Kentucky & Indiana Bridge Co. operated its suburban line between Louisville, Ky., and New Albany, Ind., by steam; but on the above date an electric system was installed, and since then a 15-minute service between the two cities has been in operation. This change in motive power was made because it was decided that by substituting electricity for steam, a more frequent service with a correspondingly increasing travel could be had at a lower cost per passenger mile. The suburban trains when operated by steam were run every 30 minutes, instead of every 15 minutes, as at present.

The Kentucky & Indiana Bridge Co.'s tracks extend from First St. in Louisville to Vincennes St. in New Albany, a distance of 4.11 miles, crossing the Ohio River on its own bridge, which is located at the foot of 32d St., Louisville. The bridge, with the approaches, is a mile in length; the bridge proper, in design a cantilever, is 2,435 ft. long, having seven spans, the longest being 483 ft. The draw span over the Indiana channel has a length of 370 ft. The bridge, a view of which is shown in Fig. 3, carries a single track railway and double highways, one on each side of the railroad.

Besides the above-mentioned tracks, this company controls and operates the Louisville Belt Line and the New Albany Belt & Terminal Railway, and runs its electric cars in connection with the New Albany Railway, an electric street railway whose cars connect at Vincennes St., New Albany, with the suburban trains of the Kentucky & Indiana Bridge Co. Of the 4.11 miles of track used by the suburban trains, 2.11 is double track, the remainder is single track, consisting of the bridge and its approaches, and an iron viaduct between Eleventh and First Sts., Louisville.

The electric trains use the bridge and the tracks above described, in common with the freight and passenger trains of the Baltimore & Ohio Southwestern Railway and the Southern Railway Co. (which roads use bridge and belt lines) and the switch engines of the bridge company, which latter are used in the transfer of freight between the industrial works, factories and warehouses on the bridge and belt tracks, and on the different railways entering Louisville and New Albany. There is an average of 270 trains run over this 4.11 miles of main track daily, of which number 141 are electric trains and 129 are steam trains and engines. The road is operated under the block system; there are ten stations on the line and the schedule time of the electric trains, including the ten stops, for the 4.11 miles is 17 minutes.

FIG. 1.—ELECTRIC AND STEAM TRAINS ON KENTUCKY & INDIANA BRIDGE CO.'S RAILWAY.

The cars are 28 ft. long, inside measurement; and the motor cars are vestibuled, with trolley-stand and brake at each end, and equipped with General Electric Co.'s W. P. 50-H. P. motors. The overhead trolley wire of No. 0 copper wire is carried upon span wires; the poles are of white cedar, 30 ft. long, and spaced every 125 ft. along the line. On the viaduct and approaches to the bridge the line is supported by arches, formed by 3-in. pipe, trussed on posts and top. The hangers on the bridge proper are of the ordinary barn type, fastened to the struts by wooden blocks. The No. 0000 stranded feeder wires are carried on the same poles with the span wires; they are carried over the top of the drawspan of

the bridge, being supported at only one point, the centre of the span, on a pivoted arm.

These electric trains have now been in operation two years.

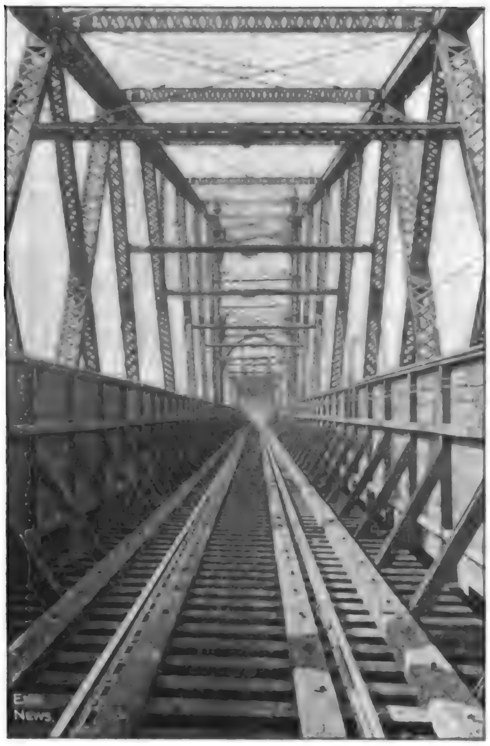


FIG. 3.—ELECTRIC AND STEAM RAILWAY BRIDGE OVER THE OHIO RIVER, LOUISVILLE, KENTUCKY.

We have never had any accident, with the exception of one derailment, which was occasioned by a misplaced switch. The electric trains are preceded and followed by steam trains. The time allowance between trains is two minutes.

Fig. 1 is a view showing an electric train passing a switch engine with a cut of cars, near 24th street, Louisville, Kentucky. Fig. 2 is a view of the Seventh street Union Depot, showing an electric train on the main track and steam trains in the shed.

Our experience for the past two years with the electric service proves to our satisfaction that the safest, cleanest, speediest and most economical method of handling suburban passenger traffic on steam railways is by trolley cars operating on the same tracks with steam trains of all classes, and that this can be done successfully without danger to the trolley cars, or detention to or interference in any way with the steam service.

FIG. 2.—ELECTRIC AND STEAM RAILWAY DEPOT, LOUISVILLE, KY

REPORT OF THE PROVIDENCE, R. I., CAR FENDER COMMISSION.

The following important report has been submitted by the Fender Commission to the Providence City Council :—

The commission appointed by resolution No. 845, approved July 10, 1895, to inquire into and report to the Council at the earliest practicable date what in their opinion is the most desirable safety fender or life guard to be placed upon the street railway cars of this city, respectfully beg leave to submit herewith a partial report.

That your commission organized on July 12, two days after its appointment, and immediately proceeded to inquire into the action taken in other cities respecting car fenders. Having examined the reports of the various commissions appointed in Baltimore, New York, Brooklyn and Philadelphia, your commission proceeded to examine into the merits of various patented and other devices, some with and some without working models, that were exhibited before them by various persons. Of these contrivances only four were regarded with favor by your commission. These were the fenders invented or owned by Arthur H. Jelly, and the Consolidated Fender Company. But your commission do not consider that these fenders are perfect. No fender should be adopted without a wheel guard, which, in the opinion of the commission, should extend entirely around the car.

Your commission are convinced that the most successful device for saving life on street railways is a light projecting fender which shall readily pass over, without injuring, the human form which it may fail to trip and catch, or which may be already prostrate; and which is supplemented by a wheel guard close as possible to the wheel to be brought into action automatically rather than by the foot of the motorman, and provided with powerful springs to bring the guard into contact with the rail and street surface.

Without a wheel guard such as has been suggested by your commission, either the Jelly automatic or the Consolidated fender may be advantageously used, but it is the opinion of your commission that there is not any fender that is always sure to save life. A good, intelligent motorman is the best preventive of accidents on street railways, and to that fact perhaps is largely due the immunity we have had in Providence from frequent accidents during the three years the electric cars have been in operation.

The managers of the railroad company have afforded the commission every assistance in the consideration of this subject, and have provided cars at all times upon which to test the various fenders submitted for trial. They have agreed to equip their cars with suitable wheel guards and with one of the fenders selected by your commission just as rapidly as it is possible to build them.

Your commission therefore submit the accompanying resolution approving the Jelly and Consolidated fenders, and unanimously recommended its passage.

FRANK F. OLNEY, Mayor and Chairman; ROBERT E. SMITH, Commissioner of Public Works; GEORGE L. VOSE, Chairman of the Committee on Railroads.

Accompanying the report was the following resolution :

Resolved, That the City Council, in accordance with the provisions of Clause X of Section 1 of Chapter 667 of the city ordinances, approved July 18, 1895, does hereby approve as a desirable safety fender or life guard, either of the rescue or safety appliances known as the Jelly Automatic Fender, or the fender

of the Consolidated Car Fender Company, provided the same is used in connection with a suitable wheel guard, and approved by the commission appointed by resolution No. 845, approved July 10, 1895.

The resolution was passed.

POWER CONSUMED BY BRUSHES IN RAILWAY MOTORS.

BY JNO. C. HENRY.

SEVERAL months ago THE ELECTRICAL ENGINEER published a contribution of mine relating to the losses in electrical machines, more particularly in railway motors, and also published a description of my magnetic brushholder, which was designed to avoid much of the wear of commutators and brushes, and at the same time to increase the motor's efficiency by decreasing the losses caused by the heavy pressure of the brushes against the commutators. I reported that in some of the old style, double reduction motors I found the practice was to use a brush pressure of about twelve pounds. This, at a car speed of twenty miles per hour, called for work equivalent to over 200,000 foot pounds per minute.

At the time of writing, the actual mechanical loss was unknown, as no data was available showing the co-efficient of friction between radial carbon blocks and the commutators. Since then we feel greatly indebted to Messrs. Cox and Buck of Columbia College whose paper published in THE ELECTRICAL ENGINEER of August 7 clears this matter up. Fig. 7 of the article referred to, shows that with radial carbon brushes the tangential pull is about the same as the brush pressure. From this data it must be evident the loss in the case I referred to was over six-horse power, from the friction of the brushes alone. Since then I have measured the pressure used on some of the more modern, single reduction machines, one class of which used eight pounds, another ten pounds. With the latter, at a speed of fifteen miles per hour, which was about the average speed of the cars, the loss appears to be about two mechanical horse power. It is quite possible that my investigations have been confined to extreme cases; but on the other hand it should be remembered that Messrs. Cox and Buck were dealing with smooth commutators, such as the railroad companies do not always use. Quite recently Messrs. Houston and Kennelly, whom we regard as excellent authority on dynamo electric machines, in their technical papers referred to the loss from brush pressure, giving the impression that the percentage could only be expressed in decimals, and that it was small and might be neglected. While this is doubtless true with large dynamos, it is incorrect as to railway motors.

Subsequent investigations may change my views, but at the present writing I am of the opinion that there is a chance to increase the efficiency of railway motors from five to ten per cent. In considering this subject it should be borne in mind that all causes in electric machines which tend to lower their electrical efficiency are of a destructive character. In the case herein referred to the brushes and commutators are being destroyed.

FAVORING THE CONDUIT TROLLEY FOR NEW YORK.

Ex-State Senator George W. Plunkitt has given much thought to the underground trolley system. He says: "I am so convinced of the excellence of the underground trolley that I have made an offer to the Eighth avenue company to put it into successful operation on half a mile of the line at Macomb's Dam. I to stand all the expenses, &c., and to foot all the loss if the system should not prove satisfactory in every way. I hope by October to have the matter settled. I want to get to work before the frost gets into the ground."

FINDING FAULT WITH THE BALTIMORE LOCOMOTIVE.

S. B. Caswell, an expert mechanical engineer of Indianapolis, Ind., has just returned from the East, where he gave a good deal of attention to the matter of substituting electric motors for steam locomotives. As a result of his investigation Mr. Caswell said: "The work of the motors is, so far, very unsatisfactory, and it is doubtful whether they will be used any great length of time. So far they have been a constant source of trouble and expense, owing to the defect in the overhead trolley system, which it is difficult to remedy. A peculiarity of the electric motor lies in the fact that its tendency is to start its load with a sudden jerk. There is no gradual acceleration of speed, but a bound forward as if the impulse were the result of an explosion. Such a motion will do for a light car, but when it comes to a ponderous mass of machinery weighing ninety tons, and attached by compact couplings to a train of cars weighing 850 tons, the impossibility of starting such an enormous weight by a sudden impulse is apparent to any mechanic. The strain on the trolley and the machinery has developed so many weak points that the most expert mechanics in the employ of the electrical companies are racking their brains in the effort to discover some new method of applying the electric force to the machinery, but so far they appear to have had little or no success. A machine of any kind that weighs 180,000 pounds, and has all its weight resting on its driving wheels, must be possessed of vast utility in order to counterbalance its disadvantages on account of the terrific strain on the tracks. Two steam locomotives, each weighing forty-five tons, would probably be as effective in moving traffic as that huge bulk of steel and iron which is proving so troublesome in the Belt tunnel."

STORAGE BATTERIES TO REGULATE THE ANACONDA TROLLEY ROAD.

A contract has been closed with the Anaconda Copper Mines for 270, 500 ampere hour Chloride accumulator cells which will be used for regulating the load on the dynamos operating the trolley line used for hauling material from the mines. The battery will also be used for lighting during two or three months of the year. For the latter work, it will be charged from the railroad circuit and discharged in 5 series in multiple.

THE SPEED THAT ELECTRIC MOTORS HAVE TO BEAT.

In the struggle for supremacy between the Great Northern Road and the London and Northwestern the distance between London and Aberdeen, which is 540 miles by the latter, has just been made in the sensational time of 8 hours 32 minutes or 512 minutes. This shows an average speed of 63.47 miles an hour over the whole distance, including all stops, which leaves all other records for such a distance far in the rear. Before these roads began their record-breaking struggle, the New York Central held the palm by making the run of 436½ miles from New York to Buffalo in 425¾ minutes actual running time, and 439½ minutes elapsed time, including all stops. On August 22, the Great Northern smashed the New York Central's proud record by making the dash from London to Aberdeen, 527 miles by its route, in 520 minutes. The same day the London and Northwestern was only a shade behind with 540 miles in 535 minutes. But the Great Northern, with its shorter route, was still fifteen minutes to the good in getting from London to Aberdeen. It was this fifteen minutes that put the spur into the iron horse of the London and Northwestern and resulted in its making the long route eight minutes faster than the short route had been accomplished. This great feat was accomplished by traveling part of the journey at the rate of seventy-five miles an hour.

A GERMAN STEAM ROAD CONVERTED INTO AN ELECTRIC.

A VERY important step has recently been taken in Germany looking to the introduction of electricity on steam roads. The first attempt of this nature is now being carried out on the branch road connecting Türkheim and Wörishofen, where the road makes direct junction with the Bavarian state railway. The cars will be of large size, each equipped with motors, and designed to haul the passenger and freight cars of the main road as trailers. At the depot at Türkheim a third standard gauge track will be equipped electrically, so that switching can be done either by steam or electric locomotives. The work is being carried out by Naglo Bros., of Berlin.

TROLLEY "LIGHT RAILWAY" FOR DERBYSHIRE, ENGLAND.

The long and animated discussion in England as to light railways appears to have fruit already in the plan for such a road from Derby to Ashbourne—12 or 14 miles—with side arm trolley suspension. It is proposed to build the generating station near the Brailsford Brook, about 7½ miles from Derby, as that seems to be the best site, the heaviest part of the road being at the Ashbourne end. If sufficient hydraulic power could be obtained from the brook a large saving might be made in generating the current. The following is a rough estimate showing the cost of the line: Cost of permanent way, including materials, laying, etc., £25,600; overhead equipment, £18,600; generating station, including land, buildings, engines, etc., £12,000; rolling-stock, including six motor cars, six travelling cars, and six goods cars, £6,100; total, £62,300 ($315,000). It is estimated that there would be 19,280 journeys made per annum, and that the mileage would be 250,000 per annum. The cost would be about 12 cents per mile, or a total of $31,000 per annum. The population of the district is about 105,000, and assuming—as is quite reasonable—that the number conveyed annually, reached that figure, the income from passenger traffic alone would come to $95,000. With regard to traffic along the road, 600 traps have been counted through the Mackworth Toll Gate on one Friday.

The Hartford, Conn., Street Railway Co. has taken an old horse car and turned it into a peach freight car, bringing the peaches in from Glastonbury for the merchants who buy them. Peaches by trolley are voted a great success down Hartford way.

JEFFREY COAL HANDLING MACHINERY IN THE COLUMBUS, O., STREET RAILWAY PLANT.

The general application of labor saving appliances to power plants, is becoming more general every day, especially in the stations of street railway companies. We illustrate herewith an installation of coal handling machinery, recently erected by the Jeffrey Manufacturing Company, of Columbus, O., in the new and well equipped power station of the Columbus Central Street Railroad Company at Columbus, Ohio. This power station is one of the finest of its kind, not only from an architectural standpoint, but also in its mechanical equipment. The Jeffrey Manufacturing Company designed the coal handling machinery for this plant. The coal which is usually nut, slack or pea is brought in ordinary railroad cars upon the side track, immediately adjoining

Coal Handling Machinery in The Columbus, O., Street Railway Plant.

the power house. The coal is then discharged into a large V-shaped hopper of a size to admit the storage of ten cars; from this hopper the coal is taken by a Jeffrey conveyer, thence under the roadway, a distance of about 100 feet, and is discharged into a Jeffrey bucket elevator inside the power house. It is then elevated to a height of 35 feet and is discharged into another Jeffrey conveyer, located upon the top of the storage hoppers. The coal hoppers are connected with the automatic stokers by specially arranged spouts, and by means of valves and levers, which are controlled by the man in charge, the coal is fed into the stokers as may be required. The coal hoppers are built of heavy sheet steel supported by wrought iron pillars. A small stationary engine drives this coal handling machinery, while the whole plant is of a capacity of more than double the present requirements of the power plant, which is now equipped with boiler capacity of 1,500 H. P.

THE NIAGARA FALLS GORGE ROAD.

The Niagara Falls & Lewiston R. R. (known as the Gorge Road) is already running over part of its track, having about five miles finished, from Lewiston to the Buttery elevator. The entire road will be seven miles double track. The company, of which Mr. J. M. Brinker, of Buffalo, is president, is getting its power from the Hydraulic Power & Mfg. Co.

"FIRED" FOR TAKING RISKS.

The Detroit Citizens' Railway Co. has recently discharged five car crews, ten men in all, for taking undue risks at railroad crossings. There is a state law on the subject and the company has also stringent rules.

PENNSYLVANIA STREET RAILWAY CONVENTION.

The fourth annual Convention of the Street Railway Association of Pennsylvania opened on Sept. 4 at the 9th Regiment Armory, Wilkesbarre. The sessions were held in the head quarters rooms, while the large drill-hall was given up to an exhibition of street railway supplies. President J. A. Rigg called the assemblage to order at 11 o'clock, and over a hundred delegates were present. Mayor F. M. Nichols welcomed the delegates cordially, but he took occasion to criticise the "greediness of the average street railway companies," several instances of which he quoted. J. R. Kenny of Berks county made the response instead of President Rigg. A. K. Balor, of the General Electric Company, spoke in the afternoon on "Power Consumption by Electric Railways." The subject was divided into two parts, the first being the apparatus itself, efficiency, etc.; second, handling methods and practices in the operation of street railways. The rest of the afternoon was taken up with general discussion on "The Laws of Street Railways," "The Prevention of Accidents and the Adjustment of Damages," "Belt Lines in Inland Cities," and "State and Municipal Taxation of Street Railways."

In the evening a complimentary concert was tendered the delegates, and on Sept. 5 there was an excursion over the Traction Company's line in the Wyoming Valley, followed by lunch.

The officers elected were B. F. Meyers, Wilkesbarre, president; John Lloyd, Altoona, first vice; R. E. Wright, Allentown, second vice; S. P. Light, Lebanon, secretary; W. H. Lanius, York, treasurer. The exhibits were good but not numerous.

A "TRILBY" CAR.

Some new trolley party cars have been built by the Philadelphia Traction Company. They have been built especially for trolley parties, and are all of the same size and design. They are reconstructed from the largest and best of the old cable cars, though little more than the frame of the old cars remain. The first car came out of the shops recently, and the other three will soon be finished. The first car is 34 feet long, and is mounted on double trucks. It has an aisle in the middle and is provided with reversible cane seats. A bronze rail at the sides prevents accidents from persons leaning or falling out. There is no foot-board at the side on which the more frolicsome spirits of trolley parties can ride. The car has been named "Trilby," and the word is spelled in letters of electric fire on the transom at each end. Its decorations are very artistic, being entirely of green and white lights, arranged on hangers of green and white China silk. There are more than 400 lights, inside and out, and the effect is said to be beautiful.

SUBURBAN RAILROAD WORK AROUND ST. LOUIS.

Mr. G. W. Baumhoff, superintendent of the Lindell Railway Co., St. Louis, has contracted to build about ten miles of road for the St. Louis & Kirkwood Railroad Co., commencing at the southwest corner of Forest Park, thence in a southeasterly direction passing through Brentwood, Tuxedo Park, Kirkwood and Meramec Highlands, which is the western terminus; returning over the same route and connecting with the Chouteau Avenue division of the Lindell Railway. For this work, 60 pound T-rail will be used throughout, and the overhead trolley wire system. This road is strictly suburban, and will, it is said, cut into the commuter traffic of two steam lines.

SIXTY-ONE MILES AN HOUR.

Since Aug. 4, the electric locomotive in the Baltimore tunnel has been hauling the entire freight service of the B. & O. line through the tunnel, and on Sept. 6, it made a speed test at the rate of 61 miles an hour, equal, it is said, to about 75 miles an hour on the level.

Mr. George Gould is reported to have sent experts to Chicago to study the working of the electric elevated road there.

The Camden & Atlantic Railroad Co., at its semi-annual meeting at Atlantic City, N. J., last week, discussed the substitution of electricity for steam on its system; but did not announce any conclusion.

The Siemens-Halske Electric, which recently acquired the Grant Locomotive Works, in Chicago, has now brought out a new steam locomotive for which many advantages are claimed. It does not propose to get left at either end of the game.

The Lenox Avenue Conduit Road has been such a success that it will be extended, and other branches of the Metropolitan system will eventually be equipped in the same way. Meantime, the company has difficulty in getting the material for its extension of the Lenox Avenue line, and has still to find out how things work in winter.

LETTERS TO THE EDITOR.

VIOLATIONS OF UNDERWRITERS' RULES IN NEW YORK.

The article which you published in your paper, under date of August 28, in relation to the disgraceful condition of the electrical wiring at St. Luke's Hospital, has been the cause of the writer receiving correspondence from contractors in this district, in which they express their appreciation that the matter has been finally taken up, and the inquiry set on foot why it is that the particular contractor who did the work at St. Luke's Hospital has been permitted at various times to do work equally as bad as, if not worse than, that at St. Luke's; and in the correspondence attention is particularly called to the electric light wiring placed in position by the contractor of the St. Luke's equipment in the New Criminal Court House, erected some two years ago on Centre street. Attention is also called to the unquestionably shameful work placed in position in the Hotel Majestic.

The writer has replied to these letters by stating that it was not his intention to attack any individual contractor or firm, but to mention a specific case of disreputable work, to say the least, for which the New York Board was primarily responsible, and which never could have been placed in position if it had not been for their action. The writer is fully aware of the conditions which existed, and which still exist on the two equipments mentioned (the New Criminal Court House and Hotel Majestic) and probably every consulting electrician and contractor in this district is also fully aware of these conditions, but they probably do not understand how it was that such conditions could arise with the New York Board having full knowledge of the facts in both cases.

The writer certainly desires to have it said to the lasting credit of Mr. Forsythe, of the New York Board, that in both cases just mentioned the work was condemned by him as improper and unfit, and that he used his best efforts to forestall the placing of such work in position.

If it had been the intention and desire to outline for the benefit of the readers of your paper, buildings in which work had been placed in position which was neither in accordance with the rules of the Underwriters, nor in accordance with the rules of good electrical engineering, a special edition of your paper would have been absolutely essential, and from daily observation made of the present class of work being placed in position in several of the buildings in this city, work of the same grade and character as that placed in position at St. Luke's Hospital is being executed.

The consulting electrical engineers and the reputable contractors (who are largely in the majority) should unite and enter upon a vigorous warfare against just such work as has been mentioned from time to time by the undersigned, and against which it is impossible for honest contractors to compete.

FREMONT WILSON.

NEW YORK, Sept. 4, 1894.

THE RELATIVE ECONOMY OF CONSTANT POTENTIAL AND CONSTANT CURRENT ARC LIGHTING.

I had not intended to again trouble the ENGINEER with any further disquisition on the above subject, but as the matter has been so fully gone into by Mr. Knowles and Mr. Wynkoop it may be timely to again refer to one interesting point in the discussion, so far not fully elucidated.

In my first communication I conceded, as claimed by Mr. Knowles, a loss in dead resistance on a constant potential arc circuit of 140 watts. While this is theoretically true, what are the facts in current practice?

Out of a very large number of specifications for arc lighting plants examined by the writer in past years, the majority called for 480 watts per lamp for constant current apparatus; that is, 50 volts per lamp times 9½ amperes, with an allowance of 5 watts, presumably for line resistance. This may fairly be considered current practice so far as constant current lamps are concerned.

Careful experiments at one of our Western universities have demonstrated the fact that a cored upper carbon gives a much better light at 8 amperes than does a solid upper at 9½. On a three-wire or other 220-volt circuit, four arcs are commonly used in series; with a dynamo potential of from 230 to 250 volts, to allow for drop in line, we can count on an average potential at the machine of not to exceed 240 volts; 8 (amperes) times 240 (volts) equals 1,920 watts, divided by four (lamps) gives us 480 watts per lamp, the same as with constant current lamps. Of course the better carbon can be used in the constant current lamp, but dealing with facts as they exist in every day practice, we get the same, or a better, light from the same number of watts with constant potential lamps as we have been using in the constant current lamp, plus a better dynamo efficiency, large units, etc. In other words, we gain at least 25 per cent. in cost of production, all factors considered.

If the cored carbons are used as they ought to be, in lamps properly designed to give a fourteen hour service with one pair of carbons, and different lengths used at different times of the year, according to the lighting hours, the cored carbons at present prices will not cost one cent more than the solid. I shall therefore answer Mr. Knowles by stating that I *should* use the constant potential system for a plant designed to do arc lighting exclusively, provided, of course, the cost of copper was not absolutely prohibitive.

But the modern engineer seldom has to deal with work calling for arc lighting exclusively; such conditions existed only in the early days of the business, before people found out that incandescent lighting could be had. Not only our cities but even our smaller villages are to-day using electric light, and there is no demand for an exclusively arc system. That system which gives us everything from one large machine of the greatest durability and efficiency, with the least possible complication, fewest employees and a minimum repair bill, is bound to survive. And it would seem that the constant potential system most nearly meets the wants of the present.

There are many things in this world which make us tired, and some things which make us more tired than other things; one of these is the constant repetition of the statement that constant potential arc lighting is not economical. The discussion to which you have so kindly given so much space may serve to show up the truth of the matter, especially when we get the figures which Mr. Wynkoop promises; we have loads of them here, from plants on a smaller scale than that in Brooklyn, and they are entirely satisfactory to those who believe in the new way of doing things.

W. N. STEWART.

MINNEAPOLIS, MINN., Aug. 28, 1895.

IMPORTANT NEW PATENT OFFICE RULE.

Heretofore inventors have been accustomed to make use of the two years' time in which to prosecute an application before a Primary Examiner in the Patent Office. The new rule allows only six months and went into effect April 15, 1895. Pending cases will be affected as though the last office decision were upon that date; therefore, all applications which were pending before that date should be amended or argued before October 15, 1895.

This is the essential feature of the rule and important at this time, because of the near approach of the limiting date, and the undersigned takes this opportunity of informing probably hundreds of inventors who may be depending upon the two years' limit.

EDWARD P. THOMPSON.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 99th meeting of the Institute, will be held on Wednesday, September 25th, the date having been changed from September 18th, by the Committee. A paper will be presented by Mr. Charles S. Bradley, on "Phasing Transformers." Meeting of Council will also be held September 25th. Applications have been received from over 30 candidates, for admission as new members.

N. E. L. A.

The Executive Committee of the National Electric Light Association proposes to hold a meeting this week to discuss the proposition to have an extra exhibit of electrical apparatus at the annual meeting in this city next year. President Wilmerding has sent a circular letter to the supply houses asking their views and advice.

CANADIAN ELECTRICAL ASSOCIATION.

This association will meet for its fifth annual convention at Ottawa, Can., on September 17, 18 and 19 when a good programe of business, papers and pleasure will be carried out. The Russell House will be headquarters.

THE NEW YORK STATE RAILWAY ASSOCIATION meets at Albany on Sept. 17.

THE OLD TIME TELEGRAPHERS meet on Sept. 11, 12 and 13 in this city, with headquarters at the Broadway Central Hotel. A royal time is expected. It will be the Fifteenth Annual Reunion.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION held its fifth annual meeting at Toronto, on Sept. 3, 4 and 5, when a number of reports and papers of interest to the medical profession were presented

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE has been holding its annual meeting, at Springfield, Mass., with wonted success. There was, however, little of interest to electrical engineers. In connection with the meeting, the Society for the Promotion of Engineering Education held its sessions. Papers were presented, with regard to electrical study, by Prof. D. C. Jackson and G. D. Shepardson.

THE OLDEST ELECTRICAL JOURNAL IN AMERICA.

VOL. XX. NEW YORK, SEPTEMBER 11, 1895. No. 384.

CONTENTS.

CITY ELECTRICIANS.

OF late years, the tendency in all electrical work has been towards specialization, and while to-day there are some men fairly well versed in many branches of the art, we doubt if a single one can be found who will assert that he is an expert in all. The younger engineers coming to the front are broadly educated in the various electrical engineering courses, but the moment after graduation, or even before it, they have made up their minds as to the particular field to which they will specially devote their energies. There are, of course, versatile men who move easily from department to department, but we fancy that their number is much fewer now than it once was; or perhaps it is that the art has widened all around them. We doubt seriously whether Mr. Edison is in close touch with some important work. Prof. Elihu Thomson has left certain branches severely alone, and Mr. Brush neglects every one. Mr. Tesla invents neither telephones nor telegraph keys. Prof. Short once sold telephone patents for a neat little sum, but to-day he is concentrated on long distance railway work. Mr. T. D. Lockwood, nimble minded as he is, has sacrificed pretty well everything for telephony. Prof. Houston writes manuals and dictionaries, and Mr. F. L. Pope has become historian to the profession.

But while all who are familiar with the magnitude of electrical development recognize the necessity of this devotion to specific pursuits, if eminent success is to be achieved, American municipalities are beginning to call for a class of men who shall unite a most bewildering range of qualities and aptitudes. We refer to city electricians, who multiply apace, and who in a few years, at the present rate of increase, will be hundreds strong. Ten years ago, there were not half-a dozen of them. Mr. Barrett, of Chicago; Mr. Walker, of Philadelphia, and Mr. Mead, of Pittsburgh, are among the first to whom the designation was applied, but even now, the titles vary and the duties are of a most onerous and miscellaneous nature. In New York, we have a Board of Electrical Control, but not a City Electrician; a good Superintendent of Fire Telegraphs—Mr. J. Elliott Smith—but no one to check the vagaries of the Board of Fire Underwriters. In Brooklyn, the work is split up between Prof. Plympton, Mr. Frank Mason and Mr. Watson; and so it goes all over the country.

We believe that the time has come when it is worth the while for cities of any size, to have a good Electrical Bureau of their own, with a good man at the head, and with competent subordinates; and the tendency of things is this way. At present, where no such central and unified authority exists, the chaos of rules, regulations, ordinances, franchises, and happy-go-lucky methods is appalling. If electricity were not the wonderfully safe thing it is, half our cities would have burned up long ago, and tens of thousands of our people would have been killed, so indefinite, uncertain and contradictory have been the control and supervision of the work done. But now, when every art and industry is being electrified, and when every city is beginning, almost in spite of itself sometimes, to have several electrical services, it is time to establish on firm ground the City Electrical Department and to have a good man at the top.

Where a city is unfortunate enough to have a municipal lighting plant of its own, the need for a City Electrician is obvious, but even when the light is contracted for, an official of integrity is needed to supervise the pole lines, see that the city gets its service efficiently, keep down the number of wires, and probably manage a subway system.

Then there is the enormous mass of inside wiring, with regard to which, until recently, few cities have had anything to say, so that electrical contractors had been bothered to death by the various insurance rules, good, bad and indifferent. Then there are the fire alarm system, the police signal system, the telephone service of the municipal buildings; and the electrical bell work from office to office. In Chicago, Mr. Barrett has lately had to deal with complicated problems of city pumping by electric power; in Davenport, Ia., Mr. Goldschmidt has had to look after the collection of a yearly tax on 5,000 poles in the street; in many cities, the questions of electrolysis from trolley lines have been referred to the city electrician; and now, last of all, many towns in Ohio have begun to put in municipal telephone exchanges, under a city officer.

We are far from regretting this magnification of the office of City Electrician. It seems to us an entirely right and proper thing, and while all these duties are a serious tax on the ability of any one man, we think that as time goes by, this type of electrical engineer will also become specialized—if only by his being a little broader man than those who narrow themselves down to determined careers in limited fields. This creation of a new market for talent should encourage the colleges that have laid out generous lines of electrical engineering study and reward them for their foresight and liberality. But it will be preposterous to expect and impossible to command the talent adequate to the work unless salaries are better. We cannot name a City Electrician whom we consider well paid to-day; and we can only hope that the increase in the duties will soon bring with it better recompense. The Patent Office cannot keep its men long, and the municipalities will not be more successful in retaining expert skill unless they give these highly trained and experienced men what they are worth.

WELSBACHS vs. ARCS FOR STREET LIGHTING.

At regularly recurring intervals we hear reports of improvements in processes of gas manufacture or gas utilization which will result in the final relegation of the electric light to innocuous desuetude. It is needless to say that thus far none of these predictions has come to pass. The most recent "scares" of this kind have been based on the Welsbach burner and on acytelene gas. The latter has hardly yet emerged from the "exhibition" stage and until more definite information is at hand as to the cost of producing carbide of calcium electrically in large quantities and inodorously no comparison can be made as to the competing power of this new aspirant for lighting patronage. But the persistency and energy of the promoters of the Welsbach light have already put more than one central station manager on his mettle. Thus far the competition has been between the Welsbach and incandescents for interior illumination; but it would seem that some energetic gas people are looking for larger fields to conquer and would even pit their new creation against the arc lamp for street illumination. The proposition seems almost ludicrous, but is nevertheless put forward with apparent seriousness by Senator McMillin, President of the Laclede Gas Light Co., of St. Louis, who claims that with the Welsbach burner streets can now be lit with gas more satisfactorily for the same money than can be done with electricity. Were it not for the cost of lighting and putting out the gas jets, he avers, the gas company could to-day light the city of St. Louis for 50 per cent. less than when the gas company had the previous contract, and give 25 per cent. better service.

It is hardly necessary to say that the statements cited above are apropos of the approaching expiration of the city electric lighting contract, and hence on that account alone ought to be taken with a grain of salt. But aside from this fact, we think that Senator McMillin would have a pretty hard time proving that gas in any form can light the streets *more satisfactorily* for the same money than it can be done by electricity at the present ruling prices for city electric light service. Whatever merits the Welsbach burner may have as an illuminant for interiors, it has *not* been proved adequate for street lighting, subject as it must be to the inclemency of the weather, street vibration, and comparatively rough handling. The cost of lighting and putting out the gas burners which has stood in the way of the reduction of cost with gas, so deplored by Senator McMillin, is unfortunately still to be contended with, but we had no idea that nearly 50 per cent. of the gas company's receipts went into the pockets of the St. Louis lamp lighters. How fortunate, for electric light companies, that a turn of a handle at the station puts them in a position to pay dividends! But whatever foundation in fact Senator McMillin may have for his statements, we think that he has reckoned without his hosts. The American public, we are convinced, has cut loose for good from gas as a street illuminant. We need only point to the number of municipal electric light plants now installed and to others going in all over this country to show that the electric light is the only light which is at all considered "satisfactory" for the purpose. No one will accuse our gas friends of lack of enterprise, but we have yet to hear of a municipal gas plant installed, in this country at least, since the advent of electric lighting. While, therefore, we apprehend no interference with street lighting work by the gas companies, the note sounded by Senator McMillin may well be considered as indicating the drift of the opinion and effort of some of our gas friends, which ought to be kept steadily in mind by members of the electric light fraternity ready to slacken the march of improvement.

WHAT IS THE SPEED OF THE TELEPHONE?

We print this week a most able and interesting communication from Mr. P. B. Delany in which he follows up and strengthens his arguments in favor of mail telegraphy. He holds to his contention that the telegraph, in its present condition, has fallen far behind the wants of the age, but he adds that even the telephone and telegraph combined barely scratch the surface of possible work. The figures do not impress us so much against the telephone, as they do Mr. Delany, for admitting that there are 40 letters exchanged to 1 telegram there are only 4 letters to 1 telephone talk, which, we think, tells more than anything else the marvellous hold that the telephone has secured on social life in less than 20 years. The number of letters would at any rate be greater by 800,000,000, or thereabouts, if we had neither electrical agency; and it remains to be seen how much further, by cheaper telephony and Mr. Delany's radical scheme of mail telegraphy, the present three billions of letters can be reduced.

This discussion is barely opened, it would seem, and we shall therefore have several occasions to return to it and the principles involved; but meantime we would greatly like to see taken up the challenge that Mr. Delany throws down to the telephone. It is of course a very serious objection that the telephone offers no record—a defect that presents an opportunity to the Gray telautograph; but Mr. Delany further says calmly that the telephone, with two wires, is good only for 60 words a minute, and, even with a stenographer, its higher capacity is doubtful. We differ from Mr. Delany in toto, but it is curious that there are no statistics in support of the high speed of the telephone. It would be extremely interesting to have an authentic, official test made; and we venture to suggest it to the Bell authorities—say for a conversation and a transmission of news between New York and Chicago. The data for argument in the case will then be more available and specific.

TELEPHONY.

THE STRUGGLE BETWEEN TELEGRAPH AND TELEPHONE.

BY PATRICK B. DELANY.

I HAVE been much interested in the attention you have been giving to the telegraph and telephone situation of late, and although in general touch with both subjects, I was startled by your graphic presentation of the power and proportions gained by the telephone during the few years of its existence.

It is easy to understand that if the telegraph and telephone continue their growth in the future in the same ratio as in the past, it will not be long before the telephone is greater than the telegraph, in property and earning capacity. Indeed, judging from the great disproportion in the development of the two systems, and the constantly increasing gains of the telephone relatively, the decline of the telegraph, if conducted on the present plans, may be reasonably expected.

There is no escape from the self-evident fact that the telephone has been managed with energy and enterprise, while the telegraph has been guardedly confined to the old conservative grooves, blind to the march of events, and deaf to the demands of development. Before the telephone was born the telegraph might have, to a large extent, occupied its field and earned a large revenue from telegraphic *conversations*. The demand for such facilities was *forced* upon the notice of the telegraph companies constantly, but the idea was frowned down, and only in rare cases, and as a great favor, were privileges of this kind granted. It is my firm belief that even at this late day type-written conferences by telegraph would be popular and profitable if the telegraph companies would take the trouble to bring people to the ends of the wire as the telephone companies are doing.

Viewing the whole subject of communication and correspondence broadly, one cannot fail to be impressed with the fact that after all the telegraph and telephone combined do but a small proportion of the work. There are about three billion sealed letters carried by the Post Office during the year, or about 40 letters to one telegram, and this difference in number is owing mainly to the difference in cost.

It might as well be admitted at once that the telephone holds the field for local communication, mainly because of the subscriber system, the lump sum yearly charge, regardless of the number of messages, and its ever ready facilities. The local telegraph, as every one knows, is slower than the long distance lines. It takes less time on an average to send a telegram from New York to Chicago than from Madison Square to Wall St. Nor is the telephone service to occasional or outside users much better in this respect, as everybody that has wrestled with a local pay station outfit, its "Hello's," "Number's," "Busy now's," etc., etc., can testify. With subscribers it is different The facilities are so much more convenient and the service so much quicker, that in these days no telephone subscriber would think of sending a telegram to his correspondent in the same town.

Leaving local communication to the mails and the telephone, the more important question of communication between distant points is the one to be dealt with, and it is to this domain that the struggle for supremacy between the telegraph and the telephone will be confined.

I cannot believe that telephony at nine dollars for five minutes' use between New York and Chicago and proportionate charges all over the country will ever become popular to any great degree, even though it should yield the 150 words per minute with which you credit it, a speed however which I think is more than double its capacity in the hands of the average user. There are but few public speakers that will average 150 words per minute in delivering an address. That such a rate can be wrung out of a telephone with all the interruptions, repetitions, and miscellaneous skirmishing in getting down to work, seems highly improbable.

It seems to me that a word a second, 60 words per minute, or 300 clearly understandable words in five minutes, would be a very liberal rate for telephony, and this without any record, unless one employs a stenographer to take it down, thereby adding to the trouble and expense, and introducing another fertile element of doubt and distraction. When it is remembered that this rate of 60 words per minute involves the use of *two* wires, the capacity of the telephone for correspondence is not as great as that of the telegraph, even with its present slow method of hand working; for a quadruplex will carry 60 words per minute over one wire. Reckoning the eight operators engaged in the telegraph work as a partial offset against the second wire of the telephone, matters will still be in favor of the telegraph with the additional advantage that in the case of the telegraph the 60 words per minute may be type-written, whereas the telephone message is in the user's head, not always a reliable reference.

The cost of 300 words typewritten by telegraph at regular rates would be $9.10, or ten cents more than the telephone charge, assuming 300 words to be a fair clean up product of five minutes' conversation.

Thus it would seem that as at present organized for work the telegraph and the telephone are about on a level. But the telephone has insuperable advantages in its subscriber system and the facilities afforded for *completing* a conference or transaction on the spot. So long as a business man in New York can, without leaving his office chair, confer with another business man a thousand miles away, and get his reply on the moment, he will pay the price *whenever the occasion warrants*, but he will not write telegrams, send them to the telegraph office and wait from one to four hours for the answer, *at the same cost*.

It is plain however that at the present rates the telegraph and telephone combined cannot get more than four or five per cent. of the number of messages carried by the Post Office. They will continue to be used in cases of urgent necessity represented by this percentage and no more.

In the battle for supremacy, the telegraph is infinitely more resourceful than the telephone. With the present system of operation, but five per cent. of the carrying capacity of the present telegraph wires isutilized, and with larger copper wires speeds may be enormously increased. Not so with the telephone; the speed of which must, under most favorable conditions, be limited to the rate of human articulation.

When telegraphy is broadened to its proper function the mails will be carried by it over all important routes, and the railway time for a letter from New York to Chicago will be practically eliminated, or reduced from about 25 hours to the telegraph speed of a few seconds—and with a rate of 15 cents for 50 words, or 90 cents for 300 typewritten words against nine dollars for the same message over the telephone, using two wires, the degree of urgency requiring the use of the telephone would be of great rarity, while at the same time, the incentive to save so much time over the regular mails would result in an enormous traffic for the letter telegraph.

No telegraph engineer will now deny that it is practicable to send 1,000 words per minute over an 850 pound per mile copper wire from New York to Chicago, producing a record from which type written translation can be made at the rate of 50 words per minute, or that 1,000 words can be prepared for transmission as quickly and as cheaply as it can be telegraphed by hand. Therefore it would be difficult to avoid the conclusion that automatic or machine telegraphy with chemical recording, will carry the bulk of the correspondence too urgent for the regular railway transportation and not urgent enough for the telephone and its great expense.

Letter telegraphy is only a question of copper, construction, and chemical automatic working. The telegraph with a differentiated service, amplified to meet the various grades of exigency, and with rates made possible by machinery which will bring into use the 95 per cent. of efficiency now wasted, should stand in no great dread of the telephone.

APPEAL OF THE BERLINER CASE TO THE U. S. SUPREME COURT.

In the U. S. Circuit Court at Boston on Sept. 3, the United States took an appeal in the Bell Telephone case involving the validity of the Berliner patent.

In the United States Circuit Court of Appeals, Judges Colt, Putnam, and Nelson sitting, Counsel J. J. Storrow for the appellant, in the case of the American Bell Telephone Company vs. The United States, made a motion for a mandate dismissing the bill brought by the United States, in accordance with the decision of this court on the appeal of the Bell Company. The Court forthwith ordered the mandate to issue, whereupon Counsel Causten Browne, for the Government, took an appeal in open court, and the appeal was allowed. The appeal takes the case before the United States Supreme Court, and has the effect of superseding the mandate, leaving the case in statu quo, to be heard anew by the court at Washington.

The first decision in this suit by Judge Carpenter was in favor of the Government. The case was taken to the United States Circuit Court of Appeals, where the decision below was reversed. The action taken by the same body now in permitting an appeal to the United States Supreme Court, settles a point of jurisdiction concerning which there had been some doubt. The right of appeal to the Supreme Court in patent causes is now most strictly limited by the creation and existence of the Circuit Courts of Appeal.

LONG DISTANCE TO LOUISVILLE, KY., OPEN.

ON Sept. 6, Mr. W. A. Vail, co-operating with Capt. Gifford and the local exchange, threw open to public use the long distance line which brings Louisville in touch with telephonic civilization. The first talk to New York was had between Police Commisioner Fred Grant and President Logan Murray, of the Louisville American National Bank.

TELEPHONES IN CASES OF SICKNESS.

THE Southern New England Telephone Co., under the able direction of President Morris F. Tyler, has always been one of the most progressive organizations in the field. It has to-day 6,446 telephones in the State limits, and has greatly developed its long distance and other services. It has at present no less than 200 men engaged on construction work.

A novel idea, just put into execution by the Southern New England Company has occasioned considerable comment. A few weeks ago a circular letter was sent out to all physicians in New Haven whose offices are connected with the exchange of the Southern New England Company, explaining the details of the plan. The letter stated the fact that in many cases sudden attacks of illness made the use of a telephone from the house of a patient to the residence of a physician of the greatest convenience. To meet this need the company announced that upon the request of a person in the city limits and with the endorsement of the physician attendant, a telephone would be placed in the house for a period of thirty days for the sum of $5, and if the family wished then to continue the service, the same rates would be made for each succeeding month.

The letter outlined a scheme which has never been tried in this part of the country, if anywhere, and its outcome has been awaited with considerable interest. Superintendent Baker was asked the other day how the plan was succeeding. He said:

"We place the temporary telephones in residences simply as an advertisement for the company to show the people what a benefit an instrument is. We have not yet met with responses enough to pronounce the idea a success, but it seems as though, in a case of illness in a family, $5 would be a nominal price for insuring prompt telephone service. We certainly are putting in the telephones for the bare cost of materials and labor. The idea was proposed by Morris F. Tyler, president of the company."

Several physicians who were asked their opinion on the matter stated that they thought the plan was an excellent one, and one which favored them exceedingly.

TELEPHONIC COMPETITION AT WABASH, IND.

A special dispatch of Aug. 22 from Wabash, Ind., says: The Central Union Telephone Company to-day submitted propositions to local business men to supply service for one year at $1 per month for business houses and 66 cents per month for residences. This is a cut of $2 per month from the old business rate, and $1.30 from the residence rate. The Central Union refused, a few months ago, to make any reduction when appealed to, and the Home Telephone Company was organized by Wabash people and a fine system is about completed. It is on this account that the Central Union makes the reduction. As the Home Company has 188 year contracts, it is letting the other fellows do the fighting.

THE FENCE TELEPHONE LINE IN COLORADO.

The Prowers County, Col., Land and Irrigation Company has established telephonic communication between headquarters at Lamar and the office at Granada. There are also four stations between the two points. The peculiar feature of this line is the fact that no wire was strung, the top wire of the railroad company's fence being used in place of the regulation wire insulated on poles. The scheme works admirably, speech being transmitted with great clearness, and there is no trouble from induction. The distance covered by this fence telephone is about twenty miles. Across Clay creek and in the towns the fence wire s connected by telegraph wire.

TELEPHONE NOTES.

LOUISVILLE, KY.—The Ohio Valley Telephone Company will be ready to do business in Louisville about the 1st of September.

ERLANGER, O.—Poles are being set through Boone County for the long-distance telephone line to New Orleans.

MENASHA, WIS.—The Wisconsin Telephone Company has been refused a franchise at Menasha, the vote being a tie of the city council.

BALTIMORE, MD.—Electricians Jacob E. Miller and Samuel R. Boone, of the City Police Department are recasting the whole telephone service, which is being greatly improved and extended. Metallic circuits will be used.

BALTIMORE, MD.—The Standard Telephone Company of Washington and Baltimore City, of Baltimore city, has been incorporated with a specified capital stock of $140,000, by Messrs. John W. Woodland, Bruce B. Gootee, General Felix Agnus, Wm. S. Thomas and Robert M. Galt, all of Baltimore, as incorporators. The directors named include all of the incorporators except Mr. Thomas, and also Messrs. Theodore J. Mayer, Elbridge S. Johnson, George W. Cross, Lemon G. Hine, Frank Hume and Wm. W. Fierce.

LAKE FOREST, ILL., is being provided with a telephone service.

MARBLE CITY, COL.—A telephone line is to be built between Marble City and Crystal.

BLOOMINGTON, ILL.—The Home Company promises to be in operation by September 1st.

MCKEESPORT, PA.—The Bell Telephone Co. is about to compete with the new local company and offers cheaper rates.

PORT BYRON, N. Y.—A telephone line has been constructed between Port Byron, Conquest and Spring Lake.

WESTMINSTER, MD.—The plant of the Western Maryland Telephone Company has been completed.

ATHENS, GA.—The Bell Telephone Company will put in at once a direct line to Atlanta.

ST. LOUIS, MO.—E. P. Woelk, manager of the East St. Louis Telephone Exchange, is looking into the matter of placing all wires in St. Clair and Madison counties underground.

SPRINGFIELD, MASS.—A branch of the Standard Telephone company, which was organized last spring is to be started in Springfield.

LEXINGTON, KY.—The new improved switchboard to be used by the telephone company is expected to arrive in about a week. This new board will be large enough to accommodate 1,000 telephones.

CHESTER, PA.—Joseph Messick, I. E. Cochran, Jr., Joseph Deering, John H. Kerlin, H. V. Smith and Ward R. Bliss have applied for a charter for the Delaware County Telegraph and Telephone Company, which will be organized with a capital stock of $25,000, divided into 1,000 shares of $25 each.

MENOMINEE, WIS., will put in at once a complete telephone system. One hundred and twenty-five instruments at first, and it is expected that number will be considerably increased. The outfit has been ordered from the Standard Telephone and Electric Company of Madison.

ELIZABETH, N. J.—Although the Elizabeth Telephone Company some time ago got a franchise from the City Council to build an opposition local line to the New York and New Jersey Company, the new enterprise lags and no vigorous effort is being made to go ahead with the work of construction.

EUREKA, MO.—In order that it might secure direct telephonic connection with its properties, the Centennial-Eureka Mining company has closed a contract with the telephone company for a branch line from the Eureka exchange to the hoisting works. The construction of the line is to commence at once.

WABASH, IND., is in the throes of a telephone war. A home company, with 180 subscribers, has been organized and will start up in a few days. The rates will be $1.50 and $2.00 per month. The Bell people have ordered an under-cut, and will probably furnish telephones free, if necessary, to kill their rival.

TUNBRIDGE, VT.—The Rapid Telephone and Telegraph Co. has succeeded the Tunbridge and Strafford Telegraph company and has established offices at South Royalton, Tunbridge, Strafford, South Strafford, Royalton, Stoughton's Mills and East Bethel. It will extend its lines to other villages at once.

CLEVELAND, O., will soon have cheaper telephones. The Subscribers' Automatic Telephone company of Cleveland is to be capitalized at $1,000,000. At the head of the local company will be a dozen capitalists and bankers who occupy prominent positions in Cleveland.

GREENWOOD, IND.—The Greenwood Telephone Company, with a capital stock of $3,000, has filed articles of incorporation. The incorporators are Grafton Johnson, J. F. Crawford and Albert Johnson. The company proposes to establish a telephone system in Greenwood.

BUFFALO, N. Y.—The contract for the use of telephones for the Fire Department has been signed. By its terms the department secures the use of 83 telephones for one year from July 1, 1895, for $960. This is $815 less than was paid for the telephones of the department last year.

NEW IBERIA, LA.—The New Iberia Telephone Exchange, a home corporation, is now placing its poles in position and gives promise of excellent service to New Iberia and the adjacent towns. The contention as to the right of the Great Southern Telephone and Telegraph Company to do business here is to be passed on later by the city council.

WABASH, IND.—A telephone war has been opened here when the Central Union Co. reduced its rates from $3 and $2 per month to $1 and 60 cents, for business houses and residences, respectively. The cut was precipitated by the home company, which is just completing its new system and which proposed to furnish service at $2 and $1.50, rates which the Central Union declined to accept.

Electric Lighting.

THE WARREN ALTERNATOR.

Our illustrations represent an alternator that has just been introduced by the Warren Electric Co., of Chicago, in which the aim has been to secure the greatest possible simplicity of construction together with the highest efficiency of operating, both electrical and mechanical. The designers of the machine Messrs. C. C. Warren and H. B. Warren, set themselves the task of building a machine without commutator or collector rings, brushes, or moving wires of any kind, and the result was the machine illustrated in Figs. 1 and 2, built on the "inductor" plan. The armature coils in this machine, shown in Fig. 3, are attached to a stationary removable laminated ring, Fig. 4, which fits accurately into the bell-shaped steel frame, the large circular exciting coil shown in Fig. 3 being attached to the steel frame. As none of the coils are attached to any movable part, it is clear that no brush or sliding contact is required.

The only revolving part of the machine consists of a cast steel cylinder, on which are pressed lamina that form the rotary poles, Fig. 5. Thus constructed the revolving portion of the machine is simply a solid mass of steel, through the polar projections of which the magnetic flux is delivered to the opposite poles of the laminated annulus to which the coils are attached. In other words, the rotating part is simply the core of a magnetic field,—the rotating flux path. It is made to fill the opening in the closed end of the frame shell so closely, and the polar projections move so extremely close to the poles of the annulus as to diminish the air gap reluctance to the smallest fraction, as shown by the fact that less than half of one per cent. of the kilowatt capacity of the machine is required for excitation.

Fig. 4.—Stationary Removable Ring Armature.

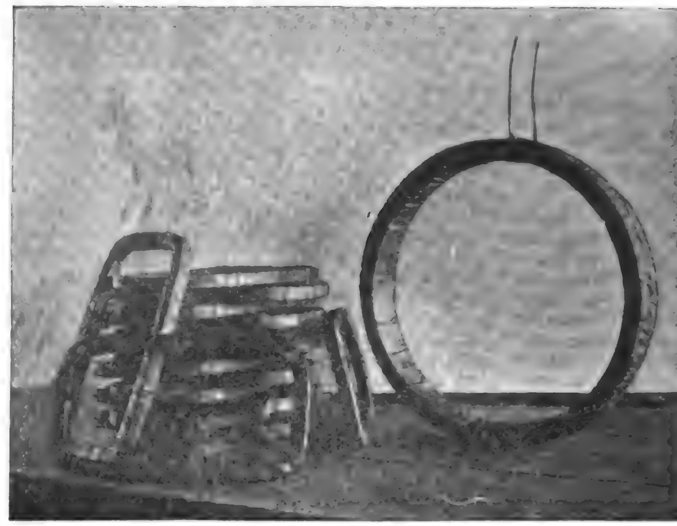

Fig. 3.—Armature Coils and Exciting Coil.

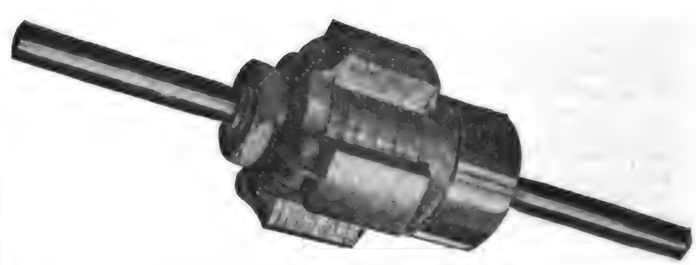

Fig. 5.—Rotating Magnetic Core.

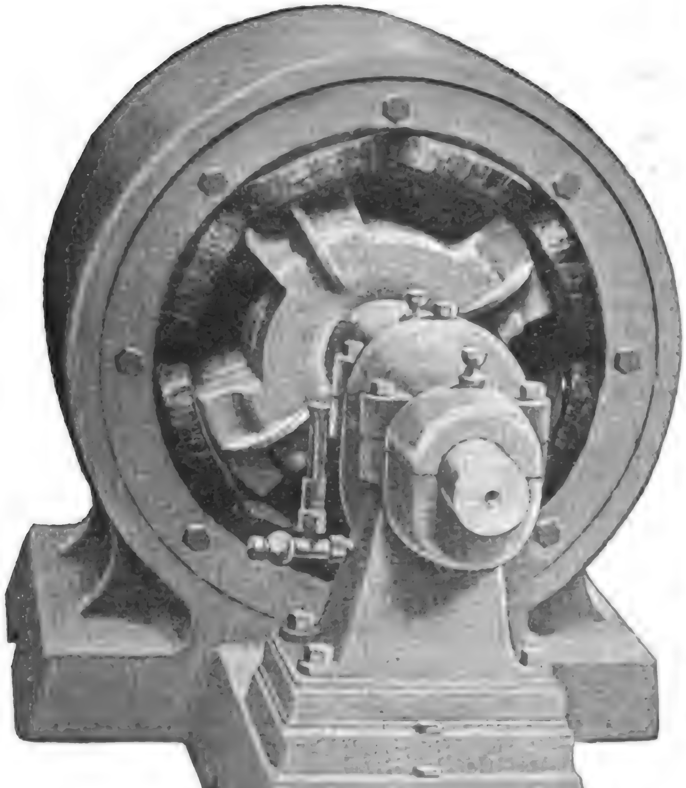

Fig. 1.—Warren Alternator, Open End, Showing Coils and Rotating Magnetic Core.

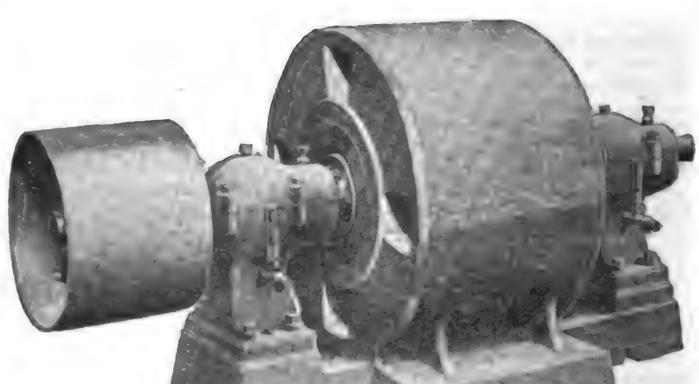

Fig. 2.—Warren Alternating Current Generator, Shown Complete.

The armature coils are wound on forms, are small, and, being attached to the stationary removable ring, are easily replaced in case of an injury from a lightning discharge or accident. Owing to the peculiar construction of the machine, it permits of various ways of connecting up for different voltages without in any manner changing the machine, or requiring new coils. Thus it may be connected for a 110 or 220 volt system, and used without

transformers for short distances; or for 1,000 or 2,000 volts to be used with transformers for long distance transmission; or it may be connected to operate a 110 volt circuit and a 1,000 volt circuit both at the same time.

Its low frequency, (7,200 per minute), adapts the machine to operate arc lamps to greatest advantage and with perfect freedom from the hissing and humming noise at the lamp, which is quite marked when run from alternating currents of the usual high frequency.

The mechanical features of the Warren alternator have had most careful consideration. The exceptionally long self-aligning and self-oiling bearings carrying a forged steel shaft of large diameter, permit running the rotor at the least possible clearance from the stationary parts; thereby reducing the reluctance due to air gap to the smallest fraction.

The 40 and 60 K. W. machines will be built as shown in the accompanying illustrations, with the frame cast of steel in one piece, making a compact and durable form of construction. In larger sizes the upper half will be cast separate and bolted to the lower half in the usual manner. Although the standard frequency adopted is 7,200, the machines will be built for any higher frequency.

KNIGHT TEMPLARS' ELECTRIC ILLUMINATIONS IN BOSTON.

The city of Boston was *en fete* the last week in August, the occasion being the holding of the Triennial Conclave of the Knights Templars, there being nearly 40,000 members of that order present. The quaint old Hub never looked so brilliant, for the citizens vied one with another in their efforts at decoration and illumination, the result being effects that were never surpassed anywhere.

It is no exaggeration to say that since the introduction of electric lighting, nowhere and at no time have more elaborate or extensive illuminations been attempted; this being the candid opinion not only of the people generally, but of those who have had charge of important undertakings of the kind, whether in Europe or America. It would take up too much space to enumerate or describe all the illuminations, but inasmuch as there were two building more lavishly adorned than the rest, it must suffice to give a brief description of those two, dismissing the rest with the statement that all of them were artistic and brilliant. These two were the immense dry goods establishment of Houghton and Dutton, corner of Beacon and Tremont streets, and the Masonic Temple, corner of Tremont and Boylston streets. The work of equipping both buildings was entrusted to the Edison Electric Illuminating Co. and was an immense success.

The first named building has a stone front nine stories high, the two sides standing on the streets mentioned.

Beginning at the top it may be said that along the cornice were the three words: "Fraternity," "Fidelity," and "Charity," formed in red and white frosted incandescent lamps of 16 C. P. capacity, there being 964 in all, the letters being four feet high and thirty-two inches wide, the outline of each letter being formed by a row of red and a row of white lamps. There was also a ring of lamps around the clock which was nine feet in diameter and composed of eighty-five red and white lamps.

Below, on the round corner of the building was the Masonic Compass and Square, ten feet in height and composed of red, white and blue lamps, the blue lamps representing the Masonic Blue Lodge. Four hundred and seventy lamps were required to complete the design. Below was the Templar's Cross, sixteen feet square, containing 1902 lamps, the two outside rows being frosted, the rest red. Then came the word "Welcome" in letters four feet high and thirty-two inches wide. This word had 370 lamps red and white. Underneath were the two letters "K. T." eight feet high and five feet six inches wide, there being 465 lamps in the two letters. On the Beacon street side appeared a "Salem" Cross ten feet high and fifteen feet wide, containing 425 lamps including red and white lamps for the borders, with purple lamps for the body. On the Tremont street side there was first the "Passion" Cross, ten feet high by fifteen feet wide, in which were 204 red lamps. A long streamer was suspended from the roof nearly to the street level down each column, and on each streamer were lamps eighteen inches apart, red and white alternately. The upper points of these streamers were united by arches, thus accurately defining the outlines of the entire building.

By means of a revolving switch, operated by a one-half H. P. motor, the lamps were flashed every fifteen seconds, so that brilliant effects were produced and the color of the entire building changed continually.

The current for this single installation of 5,692 lamps, equal to about 3,000 amperes, was taken entirely from the Edison underground circuit. About ten miles of wire were used, and the entire work was done in less than a month.

In describing the second important and imposing illumination on the Masonic Temple it may be stated that along the cornice across the front were the words "Fraternity," "Fidelity," "Charity" wrought in red and frosted lamps, there being 964 in all, the letters being 4 ft. high and 32 inches wide. Covering nearly the entire front of the building was a huge Templar's Cross 70 feet square, the outlines of which were formed by 518 red and frosted lamps. In the centre of this cross was a Salem Cross composed of 128 amber lamps. At the top of the design were grouped a Cross and Crown, composed of 120 red and amber lamps. In the left arm of the immense cross were Square and Compass, in the centre of which was the letter "G," composed of 167 blue and white lamps. In the right arm of the huge cross was a double triangle made up of 79 red and white lamps, and a Keystone of 137 frosted lamps. Each of these emblems was 10 feet square. The entire installation at the Temple was made up of 2,108 lamps requiring over 1,000 amperes of current which was taken from the underground circuit in the same manner as the larger work above described.

From the foregoing details it will be seen that no less than 7,500 lamps were in circuit; yet notwithstanding that this unusual quantity of about 4,000 amperes was called for from 7 to 12 o'clock every night, the Edison Co. experienced not the slightest difficulty in supplying the current needed.

It is generally considered that the Houghton & Dutton display was the most elaborate ever attempted. It certainly attracted the attention of hundreds of thousands of visitors during the week and was deservedly admired by all.

An idea of the general lavishness of display may be formed from the fact that the Beacon Lamp Co. supplied to the Boston Electric Light Co. some 10,000 lamps for special illuminations, 1,000 going to Keith's Theatre, which is brilliancy itself even under normal conditions.

STATEMENTS AS TO THE WELSBACH BURNER.

The last issue of the *Progressive Age* contains some very interesting data as to the Welsbach burner. As a great many of our readers are directly affected we quote some of the statements:—Messrs. W. P. Biddle & Bro., Welsbach agents at Knoxville, Tenn., write under date of Aug. 21: "We have been selling the Welsbach light since Feb. '93, and have placed about 1,500 burners, of which there are 1,500 burning. We know all the people that use our burners and when we think it is about time for them to have a new mantle, put one on. We have very little trouble with the gas-pressure. We never have to use the reamer, except where the piping in the building is clogged or too small. We only find that on old buildings, as the gas company has issued rules now for piping all buildings. The Palace Hotel, lighted with our burners, now averages a gas bill of about $45 per month, while when they used electrics it cost them about $80 per month, and ordinary tips about $75. We put the No. 29 light in halls and kitchens where there is much draft, as they give sufficient light and no chimneys break. We are experimenting now with street lights. If we don't get the city contract we will make it all the hotter for the electric light company. We have destroyed as many as five oil lamps in one place, a clothing store, and it only took about 20 Welsbachs to replace them. One drug firm here had 14 incandescent electric lights and a gas bill of $3 to $4 each month, making a total of about $17 per month. The proprietor said that if we could bring his light bill down to $10 or $12 he would be satisfied. We sold him nine burners and his bill the first month was $4.80. We have seven drug stores now using our burners. We like the mica chimney and think it a great addition to the Welsbach. One way to use them, where a user has 10 burners, say, is to buy 3 or 4 mica chimneys and keep them moved about from lamp to lamp, always keeping the micas on the worst mantles. We use now, on an average the year round, 100 mantles per month on 1,500 lamps, say."

Mr. John H. Keppelman, Superintendent of the Consumers' Gas Co., of Reading, Pa., sends in under date of Aug. 21 the following interesting information collected from their experience with lighting the streets of that city with Welsbach lights: "We have 308 Welsbach lights in successful operation, scattered all over the city. In some cases they are within 4 feet of steam railroads and at others (and most of them) close to trolley-cars. Neither of these supposed terrors has any effect on the lamps. Neither rain nor storms affect them. Bugs and flies are the only disturbing elements. We mount them in a Philadelphia-pattern square lantern closed all around. Our riser is ¾-inch pipe in which we place the necessary cock, ¾ x ⅛. Then one No. 20 Welsbach light with mica chimney, and around the Mica chimney the Welsbach No. 1028 shade made of glass tubing. The latter we think is quite an addition, as it hides the mantle, diffuses the light, and makes the lamp appear quite massive. We do not use by-passes but light with a match. Our schedule is every night and all night. Of the 308 lamps installed, the first 30 were started on April 18 last; and of these 30, 4 still have their original mantles. We believe we shall be able to operate each lamp with an average of 4 mantles per annum, and were our lanterns tight, or at least bug-tight, not more than 3, or possibly less, would be required. Our lanterns are the property of the city, and had been stored away for many years, out of service. We collected and repaired them, but they are not in the best condition. A convenient bugless lamp would be a great advantage."

Mr. Richard H. Reed, proprietor of Taylor's Hotel, Jersey City, N. J., recently wrote to his local Welsbach agent as follows: "Upon receipt of this I desire that you send a representative down, that I may confer with him in regard to fitting out the rest of the hotel with Welsbach lights. I find those I am using more satisfactory than the electric lights for my purpose, and they have saved enough in gas to pay for themselves at least twice since having been put in. They have reduced my electric light bills nearly $200 per month, and upon the installation of the Welsbach lights I desire to see your representative about, I shall discontinue electric lighting entirely."

What have electric light men to say to this? Our own comment on the situation appears on page 257.

ACYTELENE AND CARBONIC ACID AS ILLUMINANT.

According to Dr. Krüger, of Charlottenburg, Germany, a mixture of equal volumes of acytelene and carbonic acid gas can be used with all ordinary gas burners and gives an excellent light, and which is practically entirely without the explosive qualities possessed by the pure acytelene gas. Compressed acytelene and carbonic acid gas can be obtained commercially in Germany, so that gas illumination can be obtained independent of gas companies' pipes.

MARK TWAIN ON METHODS OF ILLUMINATION.

Knocking over his candle in a Vancouver hotel bedroom recently, on his way to Australia, Mark Twain remarked:—"I look on that candle as a sort of link between gloom and darkness; it is not very closely connected in my mind with the idea of light. I remember very well when most of the hotels were lighted with coal-oil lamps. They were not bad; and if you could get the hall porter to let you have half a dozen of them you could generally decipher the difference between the outlines of the bed and the bureau.

"When gas became more generally used I hailed it as a glorious innovation, and I soon discovered that the economical landlord had a way of dealing with that gaslight that left you a little bit worse off than you were with the lamps. Then came the electric light. I thought that when that came into general use we had as last got into an era of a good bedroom light, but I find that I have again been deceived. They put up a nice electrolier with about four burners on it, but you generally find that three of them have that smoky appearance that betokens a burnt out filament. You send word to the office to have it repaired. For this they keep a bellboy dressed up in overalls so as to look like an electrician. In response to your call up comes this suit of overalls with the bellboy inside of it and monkeys with the burners that won't light up. He pretends to fix them, but he never does. They continue non-illuminant up to the time of your departure.

"Besides that I find that in most of the towns they run their electric light on a fixed-hour system. The light comes in at a certain time and goes out at a certain time. In this hotel, for example, we have to go to bed as a rule with the candle, because the light quits at 2 A. M. In these fixed hour towns it does not make any difference how dark or gloomy the afternoon may be, or how early the shades of evening gather round, you cannot get your light until a certain hour. If it gets dark at 6 P. M. you have to amuse yourself chasing shadows until 8."

UNDERGROUND WIRES IN REDWOOD DUCTS.

The new Mutual Electric Light Company, Mendocino, Cal., in which P. B. Cornwall and A. Bayward are largely interested, is placing underground wires all over the city. In doing this they have discarded the use of terra cotta and substituted redwood instead. They use redwood planks three inches thick, twelve inches wide and from eight to twelve feet long. These are grooved with three to four grooves. The planks are buried four or five feet deep, and one plank placed on top of the other gives sufficient room for numberless wires.

The planks are grooved at a planing mill and taken to works where they are completely saturated and covered with asphaltum. This renders them impervious to water, and there is no reason, it is asserted, why the planks will not last from twenty to forty years.

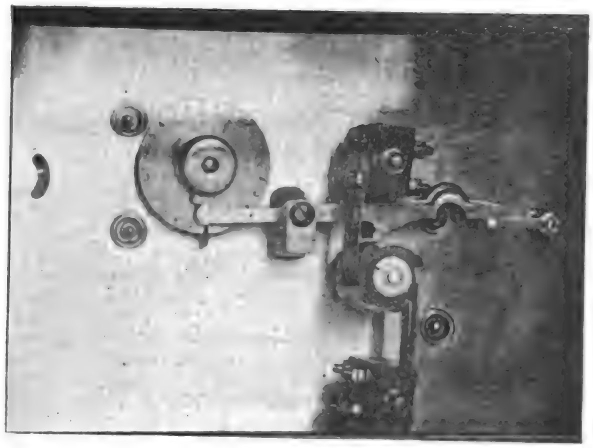
TRYING TOWER LIGHTS AGAIN.

At Springfield, Mo., a movement is on foot to have an electric light tower built in the centre of the square. It is proposed to build a steel tower eighty feet in height and have four arc lights placed thereon. One light will be located forty feet from the ground, one sixty feet and the other two on top.

THE REDDING AUTOMATIC ELECTRIC TIME SWITCH.

This instrument is designed for use in places where it is desired to light and extinguish incandescent lamps automatically at certain specified times. It is therefore particularly adapted for use in stores to light up the lamps in the show-windows on Sunday evenings and holidays; in apartment houses, to light the lamps in the halls on the approach of darkness and extinguish them at the proper time in the evening; and in many other situations where it is desired to light or extinguish lamps or turn on or turn off at more or less frequent intervals, or turn on or turn off the current for any purpose.

The instrument placed in a neat wood frame not shown in the accompanying engraving is provided with an accurate 8-day



The Redding Automatic Electric Time Switch.

clock movement and time dial to show the exact time of day and to operate the switch. The latter is double poled, very powerful in action, and will control any number of lights or quantity of current desired.

In the engraving, the time dial is shown on the left. In front of the dial are two brass wheels or cams with a single projecting tooth on each which control the action of the switch; one cam turns the current on and the other turns it off. The cams can be turned around on the dial so as to set the teeth opposite any hour desired and when so set and secured by means of a set nut, they will turn with the dial and at the designated time press on the two levers also shown in the engraving.

When the first tooth is brought around and pressed against the lever opposite to it and that lever is depressed it releases the cylinder of the switch, allowing it to make one-quarter of a revolution and closing the circuit. The switch then remains stationary until the second tooth is carried around and presses against the other lever. That lever is then depressed and allows the cylinder to turn another quarter of a revolution, thus turning off the current. The circuit then remains open until the first tooth is brought around again, when the operation is repeated. The switch can be made to operate at more frequent intervals by placing additional teeth on the cams.

This instrument, which is designed and manufactured by Jerome Redding & Co., of Boston, was originally designed for a special use but its utility and value for many purposes was immediately recognized and there is undoubtedly an extensive field of usefulness awaiting it.

CITY ELECTRIC PUMPING FOR CHICAGO.

City Electrician Barrett, of Chicago, is having measurements taken of the various engines and pumping apparatus in the different water-pumping stations throughout the city, with the idea of formulating some scheme whereby the motive power can be supplied by electricity. As soon as measurements sufficient to form a basis to work upon are submitted to Mr. Barrett, the matter will be taken up with Mayor Swift and plans drawn and estimates made as to the probable cost of the change in the system.

THE MOST NOTABLE ADVANCE.

Mr. Arthur J. Farnsworth, electrical engineer, Mamaroneck, N. Y., writes: "I believe that the advent of the Data Sheets constitutes the most notable advance that has ever been made in technical journalism."

Power Transmission.

THE EFFICIENCY OF WORM GEARING CONNECTED TO ELECTRIC MOTORS.

In a paper read before the Electrotechnical Society of Vienna, Mr. Ernst Egger described, with the aid of illustrations, various kinds of electrically-operated elevators. The author stated that when worm gearing was employed for transmitting the power direct from the motor shaft to the drum, it was particularly advantageous to use low speed motors. This expression of opinion has elicited a response from Mr. Emil Kolben, of the Oerlikon Engineering Works, who flatly contradicts that assertion in the *Elektrotechnische Zeitschrift* of August 15th.

In correcting this erroneous idea, which has generally been held, Mr. Kolben states that high speed motors should be exclusively adopted in conjunction with worm gearing, if the work is to be commercially practicable, and a good efficiency realized. It is from this standpoint that the question is of importance to electrical engineers, since, although no particular difficulties are met with in the construction of motors to run at low speeds, yet the motors are heavy, bulky and expensive, so that the use of such motors in many cases is excluded. As, on the one hand, the employment of worm gear is regarded with great mistrust, and yet, on the other, this kind of gear is the most important reducing mechanism for electrically-driven tools, cranes and lifts, and for vehicles, Mr. Kolben thinks it right that some facts should be adduced for the benefit of the electrical industry.

Proceeding to deal with this question, the author points out that a great prejudice against worm gear has hitherto existed, on account of its having been regarded in the old text and hand-books as an inefficient means of transmission; and not unjustly so, when the method of constructing the gear is considered. After referring to the work in this direction by Profs. Thurston and Kimbal and Mr. Towne in the United States, and by the late Mr. A. Reckenzaun, who obtained an efficiency of 87 per cent., and subsequently by Mr. Sellers, in Philadelphia, the author discussed the efficiency tests recently carried out by Prof. Stodola, of the Zurich Polytechnic, with the ordinary double thread worm gear of the Oerlikon Engineering Works.

The worm was 80 mm. in diameter, had a multiple ring bearing and engaged with a worm wheel having 28 teeth, the wheel being of bronze, 373 mm. in diameter. The whole of this gear was placed in oil in a cast-iron box. The gear was coupled to a 20-H. P. electric motor, and the brakeing tests were made on the worm wheel shaft. The results were as favorable as in the case previously mentioned. At 1,500 revolutions, a useful performance of 21 H. P. was given on the brake, the efficiency amounting to 87 per cent. The author, who had previously conducted a series of experiments which agreed with the result above cited, is of opinion that the efficiency with the motor fully loaded, will increase even beyond 90 per cent., if the following points are considered in the construction and fitting up of the gear for direct coupling with electric motors.

1. The starting speed should, according to the output, amount to from 6 to 12 metres per second, instead of from 5 metres to 3 metres, as has hitherto been customary. This condition necessitates the use, not only of high motor speeds, but also of a large diameter of worm, and consequently great distances between the teeth, powerful teeth, and ample bearing surface. By this means the total friction will be reduced. For the purposes mentioned the motors required range from 2 H. P. to 25 H. P., with usual speeds varying between 1,600 to 800 revolutions a minute. As the elevator drums to be operated, the driving spindles of machine tools, and the car axles of tramcars, have speeds of from 150 to 40 revolutions a minute, it is possible to obtain in the most simple manner, without any intermediate gear, the whole speed reduction by means of worm gearing, with a single or double thread worm having a ratio of reduction of 10 to 1 or 20 to 1.

2. The mechanical production of worm gear requires the greatest care, if it is to be useful for the direct coupling of motors. The worm must be turned out of a solid piece of tool steel, and be tempered, smoothed and polished. The crown of the teeth should be made of hard phosphor bronze, and if of large diameter, it should be drawn hot on to a cast-iron arm crown. The teeth are to be properly cut and polished. The whole gear is to be enclosed in a box and allowed to work in an oil bath. This arrangement will reduce the friction coefficient between steel and bronze from 0.01 to 0.005. Gear constructed in this manner runs noiselessly, has only a slight wear, and a life of several years.

3. In order to reduce to a minimum the friction of the whole mechanism on the starting of motors at full load, the pressure is taken up by starting discs arranged on both ends of the worm.

ELECTRIC POWER FOR SANTA ROSA, CAL.

A plan is on foot to utilize electrically the water power near Santa Rosa, in the canyon near Healdsburg. It is estimated that from 2,000 to 5,000 H. P. can be developed initially, and 10,000 H. P. ultimately. The distance is 17 miles.

LAKE MAY POWER FOR LEE, MASS.

A special dispatch of Aug. 26 from Lee, Mass., says: The initiative steps are being taken by parties interested to procure the water privileges on the Lake May stream, form a stock company and put in a $75,000 electric power plant that will run some 18 or 20 mills and factories in Central Berkshire. The following firms are interested: Smith Paper Company, Eaton, May & Robbins Paper Company, Hurlbut Paper Manufacturing Company, and the following paper firms: Benton Bros., G. K. Baird & Bro., Eaton, Dikeman & Co., Forest Mills, and the other investors are Clark & Spencer's, Dowd's and McLaughlin Machine Shops, and a number of smaller flour, wire and shoddy firms. The scheme is somewhat novel, and has not been tried in New England before, though it has worked successfully in Nevada and California. The lake, which is high in the mountains, is to be drawn through a conduit 18 inches at the beginning and 4 inches wide at the foot of the mountain. It will be a little over two miles long, and by the connection of a Pelton water wheel and electric machinery is expected to give a horse power exceeding 2,000, or sufficient to run all the mills within a radius of 10 miles, the power being transferred, of course, by wire.

The scheme will furnish power at one-quarter the present cost per horse power to the paper industries of the western part of the State, which are at present somewhat handicapped, because of the shortage of water in summer, and the excessive charges of freighting coal. The charges on coal are much higher than in any part of the State east of Springfield, and even in the north part of Berkshire the price is $1.50 per ton less.

A meeting of the capitalists has been held, and the scheme laid before them by Mr. Upton, an electric expert, and a committee consisting of G. K. Baird, A. W. Eaton and E. S. Rogers was appointed to see what could be done with the present owners of mill privileges on the stream. Mr. Upton says it is the only location in the State where an almost direct fall of 600 feet can be obtained, and it will be a boon to the manufacturing interests of Western Massachusetts.

TO DEVELOP POWER AT TOPEKA, KAN.

There is a gigantic scheme on foot by an eastern syndicate, says the *Topeka Journal*, to buy all the private electrical plants in the city and consolidate them under one management. The same syndicate, it is reported, intends to purchase the street car lines, and to build the lower dam, by means of which it will operate both the lights and the cars with water power. The deal has not yet been consummated, but the indications now are that it will be made. Early last spring Congressman T. E. Burton, of Cleveland, O., was in Topeka for a week. When he had gone it was announced that a Cleveland syndicate had purchased the Brush electric light plant. Congressman Burton did not represent himself alone and the syndicate which he was behind is said to be able to control almost any amount of money. W. W. Hazzard, of Cleveland, is another of the prominent members of the syndicate. This action of the Cleveland syndicate has another meaning. An attempt has been made to get these same gentlemen interested in the construction of the lower dam, and it is reported that the representatives of the dam company were successful, except that the syndicate has a condition attached and that is that they succeed in the consolidation of the electrical companies in Topeka.

The reason of this is evident. If they had control of the electrical plants in the city they could secure their supply of electricity from the power house at their own dam and thus operate their plants at a small expense. So that if the syndicate succeeds in the purchase of the plants in Topeka they will also build the lower dam.

The Cleveland syndicate also includes the gas plant in their designs and it will also be purchased if the plan is successful. J. B. Bartholomew is the man who is now manager of the Brush plant, and he is representing the interests of the Cleveland capitalists, and that fact adds to the probable truth of the report that if the syndicate succeeds in purchasing the electrical plants they will also build the lower dam.

UTILIZATION OF THE LACHINE RAPIDS, MONTREAL.

It is over a year since the Lachine Electric Lighting corporation received water power privileges at Lachine Rapids from the Dominion government for the purpose of generating electric current and transmitting it to the city of Montreal. After incorporation on a two million dollar basis the next move was the acquirement of land at the site of the magnificent water power. That matter has been attended to and a splendid site has been chosen that will meet all the exigencies and requirements for many years to come.

Financial matters and stock takers were the next affairs to be looked after and for that purpose it is evident, says the Ottawa, Ont., *Free Press* of Aug. 23, that the management of the corporation has been keeping its eye on Ottawa. Yesterday Mr. McLea Walbank, of Montreal, arrived at the Russell and

was assigned a room next to that occupied by Mr. G. B. Burland. This morning the news was around among the financial men of the city, that G. B. Burland had taken shares to the extent of $50,000. This forenoon Mr. R. M. Cox, the millionaire timber merchant of London and Liverpool who by reason of his recent heavy investments in Ottawa and Canadian affairs, and his annual half year's stay with us may be safely considered one of us, was closeted with Mr. Walbank for a couple of hours, and the news spread around with equal rapidity to the former case, that he also was a shareholder carrying a large sized amount of stock which is universally believed to be $30,000.

POWER FROM THE SAN LORENZO RIVER, CAL.

News has reached Santa Cruz from San Francisco that Mr. Fred W. Swanton has made terms with Henry Cowell for the purchase of his water rights on the San Lorenzo river, and that if sufficient co-operation from the citizens can be secured, there is a possibility of placing an electric power that will give Santa Cruz a boom in locating minor manufacturing establishments and make light, heat and power cheap.

POWER AT STEVENS POINT, WIS.

Stevens Point is figuring on making use of its water power to generate electricity for the running of machinery in the city. It is claimed that the water power is sufficient even in low stages to furnish 1,500 horse power. Primarily, it is to run the water and light works and the electric street cars, but incidentally, it will furnish power wherever it is wanted. They claim that it can be furnished at a cost of $30 per horse power per year while steam costs $50. Then it will save on insurance and be ready for use without firing up and be used only in such quantities as may be wanted. This is eminently practical. They certainly have an immense power going to waste which can be distributed all over the city very cheaply.—*Milwaukee* (*Wis.*) *Journal.*

MISCELLANEOUS.

SCIENTIFIC USES OF LIQUID AIR.—IV.

BY PROF. J. DEWAR, F. R. S.

(*Concluded.*)

A second series of experiments were made with a set of cast test pieces of metals and alloys. The test pieces, all cast in the same mould, were 2 in. long with ½in. spherical ends, the cylindrical portion being two-tenths of an inch in diameter. The spherical ends of the test pieces rested in similar cavities made in a special set of steel supports that fitted on to the testing machine. Crystalline metals give castings that are far from uniform one with another, and it is very difficult to get even comparable results with methods like zinc, bismuth and antimony. The following table gives the experimental results:—

TABLE II.

BREAKING STRESS IN POUNDS OF CAST METALLIC TEST PIECES. DIAMETER OF ROD 0.2IN.

—	15°C.	– 182°C.
Tin	200	390
Lead	77	170
Zinc	35	26
Mercury	0	31
Bismuth	60	30
Antimony	61	30
Solder	300	645
Fusible metal (Woods)	140	450

It will be noted that in this list the breaking stress, by cooling to —182° C., has been increased to three times its usual value in the case of fusible metal, and to twice its usual value in the case of tin, lead and solder. The results with zinc, bismuth and antimony are exceptional, seeing they appear to be diminished in tenacity. This, however, may be only apparent, because the stresses set up in cooling such highly crystalline bodies probably weaken some set of cleavage planes so that rupture is then comparatively easy. In any case is must be admitted that no reliance can be placed on the tenacity of highly crystalline metals. The breaking stress of mercury is interesting, and turns out to be at —182° C. nearly half that of lead at the ordinary temperatures.

The percentage elongation is not given in the foregoing tables, simply because the value of such measurements is of little importance when such short pieces of the metals are under observation. The general results of such observations are, however, interesting; thus, lead and tin at ordinary temperatures elongate before breaking about the same amount, whereas if tin is cooled to —182° C. it hardly shows any extension, and lead under such conditions shows no change, stretching as much at —182deg. as at 15° C. Solder and fusible metals stretch less, and the cross-section of the break is much less at —182deg. than at 15° C.

The above experiments can only be considered as preliminary to a more elaborate investigation of the actual variation of the elastic constants at low temperatures. It will require complex experimental arrangements to get reliable measurements of the Young modulus and the rigidity modulus at the temperature of boiling liquid air. In the case of fusible metal, a first attempt to compare the ratio of the Young modulus at 15 deg. and —182 deg. with the ratio of the rigidity modulus between the same limits of temperature, has resulted in finding that both constants are increased in the same proportion. From this it would follow that the resistance to compression of the substance at —182° C. must be increased in a similar ratio. The comparative behavior of strong steel spirals at 15° C. and —182° C. as to their elongation on the repeated addition of the same load was a subject examined on several occasions. The most careful comparison of such spirals, however, revealed no measurable differences in their elongation between the ordinary temperature and that of boiling oxygen. This may be due to the want of sufficient sensibility in the testing machine when applied to such delicate experiments. In the meantime it is reasonable to conclude that the rigidity modulus of very hard steel is not much changed by cooling it to —182° C. If balls of iron, tin, lead or ivory are cooled to —182° C. and dropped from a fixed height on a massive iron anvil the elastic rebound is markedly increased in all cases. The flat distortion surface produced on the lead sphere after impact is only one-third the diameter of the circular surface produced at the ordinary temperature when the lead ball falls from the same height.

The examination of the magnetic condition of matter at low temperatures is a subject of great interest and offers a wide field for investigation. In a former lecture the magnetic properties of liquid oxygen and air were discussed. Owing to the experimental difficulties, accurate quantitative measurements of the permeability have not yet been successful. Faraday was the first experimenter who examined the magnetic condition of matter at the lowest temperature that could be commanded in his time, viz., about — 110° C. He did not succeed in making any substance which was non-magnetic at ordinary temperatures assume the magnetic state at the lowest temperature of the solid carbonic ether bath in vacuo. Later experimenters have directed their attention more especially to the action of high temperatures on magnetism, and the work of Profs. Hopkinson and Ewing in this field of research is well known. Prof. Trowbridge examined the effect of a temperature of — 80° C. on a permanent magnet, and came to the conclusion that the magnetic moment was diminished by about 50 per cent. Prof. Ewing found that an increase of temperature of 150° C. above 10 deg. caused a reduction of the magnetic moment of a bar magnet by about 40 per cent., and that the magnet on cooling recovered its original state. This result would lead us to expect that if the same law is followed below the melting point of ice as Ewing found above it, then a bar magnet cooled to — 182° C. ought to gain in magnetic moment something like 30 to 50 per cent. The experiment of Prof. Trowbridge is, however, apparently opposed to such an inference. It appears however, that Prof. Trowbridge cooled a magnet that had not reached a constant state (that is to say, one that on heating would not have completely recovered its magnetization on cooling), because after the magnet had been cooled to — 80 deg. on regaining the ordinary temperature, it had lost 50 per cent. of its original magnetic moment. Such a magnet would apparently diminish in magnetic moment on cooling and heating the first time the action was examined, but a repetition of the process when the action of magnetization and temperature were strictly reversible might lead to an opposite conclusion. To settle this question a series of experiments on the magnetic moment of small magnets cooled to — 182 deg. were carried out. Small magnets from half an inch to an inch in length were made of watch-spring or steel wire, and were either used separately or in bundles; they were fixed rigidly in a block of wood by means of copper staples, and in this condition were easily clamped firmly in the field of a magnetometer. The cooling was effected by applying a cotton-wool sponge of liquid air. The relative deviations of the magnetometer are proportional to the magnetic moment of the magnet under the respective conditions of + 15° C. and —182° C. After the first cooling the magnet is allowed to regain the ordinary temperature, and the operation of cooling and heating is repeated three or four times. The following table gives some of the results, and these may be taken as typical of a large additional number unrecorded.

If the experiment marked (1) is examined we find cooling to — 182 deg. in the first cycle produced no change of magnetic moment, but that on heating to +15° C. the magnet had lost 30 per cent. of the original strength. In the second cycle cooling increased the magnetic strength of the magnet in the condition in which it is left after the first cooling by 33 per cent., and heating

diminished it by 5 per cent.; whereas in the third cycle cooling showed 36 per cent. increase, and no loss in heating. It was only after three alterations of temperatures from +15° C. to —182° C. that the magnet reached a steady condition. In experiment (3) the first cooling shows a loss of 24 per cent., while in experiment (4) the first cooling shows a gain of 12½ per cent.

CHANGE OF THE MAGNETIC MOMENTS OF PERMANENT MAGNETS AT +15° C. AND —182° C. PER CENT. OF THE VALUE AT THE BEGINNING OF EACH CYCLE, WHICH IS ALWAYS 15 DEG.

——	— 182° C.	+15° C.
(1) Hard steel, 0·5in. long and 0·4in. diameter		
First cycle	+ 0	— 30·0
Second "	+33·0	— 5·0
Third "	+36·0	0
(2) Soft steel.		
First cycle	+12·0	— 23·0
Second "	+51·0	0
Third "	+51·0	0
(3) Hard steel, 1·03in. long, 0·4in. diameter.		
First cycle	—24·0	— 43·4
Second "	+23·0	0
Third "	+23·0	0
(4) Nine steel wires in bundle.		
First cycle	+12.5	+ 3·0
Second "	+33·0	— 2·0
Third "	+33·0	0
Tested four days after.		
First cycle	+50·0	0

It is clear, therefore, that according to these experiments, every magnet has individual characteristics that may either result in no change on cooling or the addition or subtraction of from 12 to 24 per cent. in the magnetic strength. All the experiments, however, show that a repetition of the cycle of heating and cooling brings the magnet to a steady state, in which cooling always causes increase in the magnetic strength of from 30 to 50 per cent., and the re-heating brings about no loss in the original magnetic moment. Such a marked alteration in magnetic strength might be used as a thermometer in low temperature research, and it is my intention to extend the inquiry to the lowest temperature that can be reached by the evaporation of nitrogen in vacua. A simple mode of showing the sudden alteration of magnetic strength on cooling is to surround a permanent magnet made up of a bundle of steel wires with a coil of copper wire, leaving the ends of the magnet to project so that they can be dipped in liquid air. When the copper wires are attached to a galvanometer, and one of the ends of the magnet cooled, an induced electrical current occurs, due to the sudden magnetic change. Accurate observations must be made on the permeability and susceptibility of the magnetic metals at the temperature of boiling liquid air, and the above results are an indirect guarantee that this field of investigation will be fruitful in new scientific facts.

This lecture has already covered a very wide field. It is easy to put into a Friday evening discourse the work of a year. Members and friends have chiefly contributed to the research fund, which has enabled the Institution to extend the experimental plant needed for the prosecution of research in this field of inquiry, and they have strong claims to learn, in the first instance, the results of the general laboratory work. My object has been to illustrate the scientific uses of liquid air. To do this with any satisfaction requires what may be called a good deal of scientific prospecting. Is is one thing to discover where the ore lies, it is another thing to produce the refined metal. Investigations on the properties of matter at the temperature of boiling liquid air, must be in the first instance rather qualitative than rigidly quantitative. In my opinion, scientific progress is best served by conducting the inquiry on these lines. It will be easy to refine later on.

I have to acknowledge the great assistance I have received in the conduct of these experiments from my excellent chief assistant Mr. Robert Lennox, and I must also express commendation of the way Mr. Heath has helped in the work.

TEST OF ALUMINUM IN SEA WATER.

SOME months ago two plates of aluminum were sent to the Norfolk Navy Yard to be tested as to their ability to resist the action of salt water. One of them was pure aluminum, weighing 2 pounds 9 ounces; the other contained six per cent. alloy of copper. They were immersed for forty-five days, and at the end of that time the plate of pure metal was found to be only slightly affected, and the aluminum wire by which it was suspended was perfectly intact. It had lost half an ounce in weight. The alloy plate was found to be corroded and roughened over its entire surface, the wire by which it was suspended was eaten entirely away, and it had gained half an ounce in weight by corrosion.

The plates were again immersed, this time for three months. The report of this test, recently received at the Navy Department, says that the pure plate was slightly roughened over its entire surface, and that there were a few barnacles attached. After being cleaned it was found not to have changed in weight. The alloy plate was found covered with barnacles and corroded to a greater degree than the plate of pure aluminum. It was not weighed.

A practical test was made of aluminum in the construction of small boats by Mr. Walter Wellman, who had three constructed to carry his polar expedition last year. These boats, it is said at the Navy Department, have been brought back to Washington, and an examination made some time ago showed that the material had so deteriorated that it could be easily crumbled in one's hand.

ACTION OF THE ELECTRIC CURRENT ON FUSED SULPHIDES.[1]

BY JULES GARNIER.

AFTER having determined that carbon, heated to redness under the influence of an electric current of feeble voltage, is transported from the positive to the negative electrode, which fact permitted me to indicate a new method of iron cementation, I thought that this action of an electric current ought not to be limited to carbon. To determine this fact, I made experiments in the laboratories of M. Hillairet. I employed a tube of refractory material placed horizontally in a reverberatory furnace, and receiving the matter to be electrolized between the two electrodes in the heated part of the tube. The current was furnished by a Gramme machine. I operated it first on a raw nickel matte from Sudbury, Ontario. I placed a certain quantity of it in the middle of the tube between the two carbons. The spaces between the carbon rods and the walls of the tube were filled with refractory earth mixed with charcoal, to guard against the intrusion of oxygen, but not the exit of gas under feeble pressure which is formed during the electrolysis, and which can thus escape by the cracks which the heating produces in the clay mass. The matte being melted, I passed a current of 10 volts and 23 amperes; the current only showed feeble oscillations according to the voltmeters, proving that there was a great regularity in the conductibility of the molten mass. Moreover, the voltage was gradually lowered, although the temperature of the reverberatory furnace was almost constant, which went to prove that the nature of the mixture was changed. After an hour of heating, slow cooling and stoppage of the current, I opened the tube. The positive carbon rod was worn to a feather edge at its upper end, while the negative rod remained intact. Of the matte an analysis was made of those parts which were solidified at the point of contact of the two electrodes. Only the insoluble parts which existed in fragments of the walls of the tube strongly attached to the matte, even after cooling, were eliminated from the samples. Of the analyses given below, No. 1 is of the matte taken; Nos. 2 and 3 are respectively those of the material in contact with the anode and of the cathode after the electrolysis, and No. 4 shows an average of Nos. 2 and 3.

	(1)	(2)	(3)	(4)
S%	21.10	16.60	4.70	10.65
Fe%	33.30	35.40	49.10	42.30
Ni%	16.30	5.18	19.10	12.14
Cu%	29.00	39.90	26.13	33.02
	99.70	99 20	99.03	98.11

These analyses show that 50% of the sulphur is eliminated, which sulphur keeps with the copper, especially near the anode; that the iron remains near the cathode, where it seems to accumulate according to the average analysis, No. 4; that the nickel regularly increases in quantity from the anode to the cathode, and the copper diminishes in a regular arithmetical progression from the anode to the cathode. I think that one may conclude from the results of the above experiment that (1) the sulphur combined with the metals in the molten state, in the absence of air, when traversed by an electric current (the electrodes, at least, the anode, being of carbon), is gradually eliminated in the form of sulphide of carbon; (2) in a mixture of molten metallic sulphides, in the absence of air, traversed by an electric current, the electric conductivity of the mixture remains homogeneous at every moment, increasing little by little on account of the gradual elimination of sulphur; the metals and the remaining sulphur arrange themselves in such a way that each elementary section of the bath taken perpendicularly to the direction of the current, has the same electrical conductivity; thus the copper, a better conductor than iron or nickel, keeps the greatest portion of the sulphur, so that its conductivity may be reduced in the desired proportion.

It is possible, I think, from the above experiments, to explain certain observed phenomena; for example, the mode of distribution of the metals free from, or combined with, sulphur in veins.

ELECTRIC FURNACES AND THEIR APPLICATION TO THE TRANSFORMATION OF CARBON INTO GRAPHITE.[1]—I.

BY CH. STREET.

The honor of reading this Paper belonged of right to my colleague M. Charles Girard, and I have to thank him for having allowed me to give you an account of our labors.

Before describing our methods of transforming carbon into graphite, methods which are founded upon the employment of special electric furnaces, we thought it would be a good thing to review for your benefit the interesting attempts that have been made in the direction of applying electricity to metallurgy, by making use of the extremely high temperatures placed at our disposal by the electric current. We thought it appropriate for the Société Internationale des Electriciens to record the results obtained, in order that it might assist progress towards the distant goal which we shall certainly reach in the future. The limited scope of this communication and the fear of tiring you by a too detailed *exposé* obliged me to limit the number of inventions to which I shall call your attention.

Apparatus in which heat is produced by means of electricity

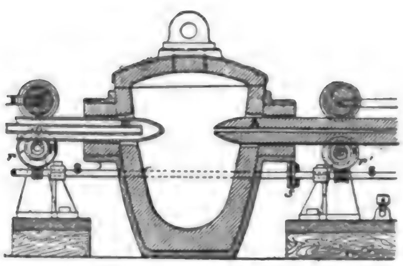

FIG. 1.

may be divided, like electric lighting apparatus, into two large classes; some furnaces are based on the incandescence of a resisting portion of the circuit, the others on the use of the electric arc. The latter are those which enable us to obtain the most powerful effects and which it would seem are destined to yield the most valuable results.

The International Electrical Exhibition of 1881 acquainted us with the two first electric furnaces which may be regarded as the starting point of all apparatus of the kind. The apparatus exhibited by Messrs. Siemens consisted of a carbon crucible heated by an electric arc in the interior (*see* Fig. 1). The carbon crucible containing the substance to be heated had two apertures through which the electrodes passed. A carbon lid enclosed the contents. The electrodes were either both of carbon or the positive was of carbon and the negative was of metal and kept cool by circulating water. The electrodes were fed forward automatically as they

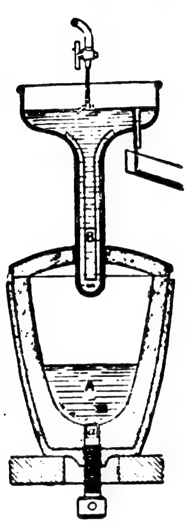

FIG. 2.

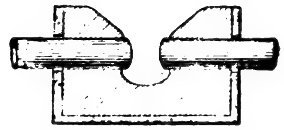

FIG. 3.

were consumed by means of a device which I will not stop to describe. The Siemens electric furnace could be arranged in another way when the material in the crucible was a good conductor of electricity. The current was brought to the bottom of the crucible by a platinum screw *a* (Fig. 2) and transmitted to the conducting substance A, which was thus placed in connection with the positive pole. An arc was established between A and the negative pole B, which was cooled by circulating water.

The second piece of apparatus to which I will allude is that of our colleague M. Louis Clerc. This consisted of a block of magnesia or carbonate of lime (Fig. 3), in which a cavity was hollowed out where the arc played. The electrodes consisted of two 20mm. carbons. In this furnace its inventor volatilized silica and lime.

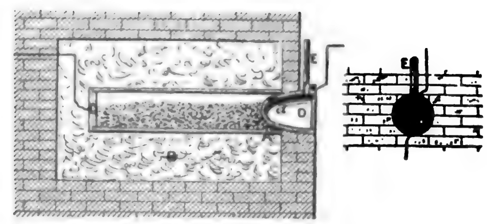

FIG. 4.

If my memory serves me aright M. Clerc, who publicly repeated his experiments every evening before the visitors to the Exhibition, sent M. Daubrée some very curious specimens of crystalline lime, products of the condensation of the substances volatilized in his furnace.

In 1885 Messrs. Eugene and Alfred Cowles took out a patent for an electric furnace which was the starting point of their interesting work on the production of aluminum. In this furnace the heat was produced by bringing the material to be treated to incandescence by means of the electric current, the charge being previously pulverized and mixed with powdered retort carbon (Fig. 4). The first apparatus which was made was intended for the reduction of zinc ores, and its use was extended to the reduction and fusion of other ores, especially aluminum, silicium, magnesium, and boron ores. This furnace consisted of a cylinder A, made of silica or any other non-conductor of electricity. This cylinder was surrounded with powdered charcoal B, or any other bad conductor of heat. One end of the retort was closed by a plate of carbon C, which formed the positive electrode. The other end was closed by a graphite crucible D, which formed the negative electrode. This crucible, at the same time as it served as a negative electrode, formed a gas-tight plug for the retort and a condenser for the zinc vapor. The charge, a mixture of ore and carbon, was introduced through the aperture closed by the crucible.

1. Paper read before the Société Internationale des Electriciens.

NEWS AND NOTES.

REPORTING THE INTERNATIONAL YACHT RACE FROM MID-OCEAN.

General Manager Ward and his colleagues of the Commercial Cable Co., as well as the staff of the Postal Telegraph Co., made a great hit on Saturday last by running out a special cable to the scene of the great initial race between the "Defender" and the "Valkyrie III." The "Mackay-Bennett" cable steamer with 14 miles of Siemens cable, hitched on to the Commercial Cable system, through its Coney Island shore end, and then ran out to the Sandy Hook race course. On board the moving steamer was a corps of telegraph operators, an office was thus set up in mid-ocean, and all the world, including New York, got the news of the progress of the race and the victory of the "Defender," instantaneously. It was a big idea and a brilliant success. The work is to be repeated each race day, and the "Mackay-Bennett" will carry the usual day and night cable laying signals.

ELECTRIC ELEVATOR WANTED FOR PARIS, TEXAS.

The Treasury Department, through the Office of the Supervising Architect, is inviting proposals until September 20, for furnishing and erecting, complete, an electric elevator (passenger) for the United States Court House and Post Office Building at Paris, Texas.

Respective bidders may address for further particulars, Hon. H. R. P. Hamilton, Acting Supervising Architect, Treasury Department, Washington, D. C.

TAXING POLES IN DAVENPORT, IA.

Each pole in Davenport is to be taxed 50 cents a year, and the City Electrician, Mr. Goldschmidt, estimates that the 5,000 poles in town can be reduced 20 per cent., an end that the tax will materially assist. The city electrician now has supervision also of all inside wiring.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED SEPT. 3, 1895.

Alarms and Signals:—

Railway Block Signal System, A. W. Hall, New York, 545,494. Filed June 15, 1895.

Electric Signaling Apparatus, J. H. Fildes, Chicago, Ill, 545,469. Filed June 12, 1895.
Consists in means for controlling the transmission of the signal actuated by a passing locomotive-engine or train.

Signal Box, N. H. Suren, New York, 545,689. Filed Mch. 6, 1895.
Increases the length of the stud on the outer door which operates the non-interfering plunger by making such stud telescopic in construction. Improvement on the Gardiner system.

Electric Alarm, W. S. Hull, Dallas, Texas, 545,658. Filed Nov. 26, 1894.
A special form of relay.

Semaphore Signal for Railways, J. W. Lattig, West Bethlehem, Pa., 545,701. Filed Jan. 5, 1895.
The semaphore carries a number of incandescent lamps which are illuminated in rapid succession by means of a revolving switch.

Indicator, B. F. Rittenhouse, Philadelphia, Pa., 545,736. Filed Apl. 13, 1895.
The push button encloses a coil with vibrating core the sound of which indicates the integrity of the circuit.

Electric Signaling Apparatus, B. Price, Baltimore, Md., 545,815. Filed April 24, 1894.
A device for sending a fixed combination of electrical impulses over the line and a receiving device for selecting the signals.

Electrical Burglar Alarm, J. R. Alexander, New Albany, Ind., 545,835. Filed March 20, 1895.
Wires are run through grating bars which protect a window; the alarm is sounded when the grating is disturbed.

Conductors, Conduits and Insulators:—

Cleat for Electric Wires, M. M. Wood, Chicago, Ill., 545,690. Filed Jan. 11, 1895.
In a cleat for electric wires, a body having a slot, the opening of which is substantially parallel or in line with the length of the wire, and which is curved within the cleat so as to form a hump or bend on the wire to prevent its longitudinal motion.

Electric Insulator, D. M. Rithenberger, Lancaster, Pa., 545,819. Filed March 8, 1895.
The insulator is provided with a transverse ligament around which the tie-wire is passed, the said wire then being twisted around the main wire.

Distribution:—

Electric Transformer, W. F. Brittin, Allegan, Mich., 545,670. Filed Nov. 16, 1894.
Relates to the form of the laminated core and the arrangement of the windings, the secondary being placed between portions of the primary.

Dynamos and Motors:—

Electric Motor, J. O'Neil, New York, 545,524. Filed June 2, 1894.
The armature has three poles revolving in a two pole field.

Alternating-Current Generator or Motor, E. Thomson, Swampscott, Mass., 545,554. Filed Sept. 29, 1891.
A field magnet and an armature magnet having a series of coils and the other having its poles subdivided into separate polar projections spaced according to the scale of spacing of the poles for the first.

Electric Coal or Rock Drill, H. H. Bliss, Washington, D. C., 545,570. Filed Sept. 6, 1888.
Details relating to a motor designed for strength and compactness.

Electric Motor, O. E. H. Kramer, St. Louis, Mo., 545,591. Filed Apl. 23, 1894.
Details of construction of a multipolar motor.

Electric Motor, O. E. H. Kramer, St. Louis, Mo., 545,593 Filed May 10, 1894.
Details of construction relating to two motors coupled to the same shaft.

Method of and Apparatus for Controlling Currents for Electric Motors, T. Von Zweigbergk, Cleveland, Ohio, 545,664. Filed Nov. 1, 1894.
A car controller with special devices for shortening the duration of the arcs by dividing the contact spaces.

Asynchronous Motor, M. Hutin & M. Leblanc, Paris, France, 545,698. Filed Apl. 19, 1895.
The method of starting and running single phase alternating current motors in either direction, which consists in rotating in the direction to be given to the armature and between the same and a circular row of alternately wound field magnets, a flux screen containing circuits closed upon themselves, and passing single phase alternating currents through the field coils.

Rotary Field-Motor, A. E. DuBois-Reymond, Berlin, Germany, 545,853. Filed Dec. 26, 1893.
In a rotary current motor the combination with a number of coils each connected at intermediate points with a number of contact terminals, said contact terminals being arranged in a circle, of a number of brushes, one for each coil, mounted to be moved over said terminals and adapted to make contact with corresponding terminals of the several coils whereby the effective lengths of the several coils may be varied at will.

Electric Tool and Machine, H. H. Bliss, Washington, D. C., 545,569. Filed Dec. 24, 1886.
A motor arranged to drive a boring bar. Intended for mining work.

Lamps and Appurtenances:—

Electric Arc Lamp, R. H. Jahr, Opladen, Germany, 545,694. Filed Nov. 26, 1894.
Consists in an auxiliary resistance determining the current flow through the regulating-helix and a connection between this auxiliary resistance and the main regulating resistance of the lamp, whereby both these resistances are caused to move in conformity with the current intensity and current tension necessary for the degree of brilliancy desired.

Electric Arc Lamp, R. Segerdahl, Chicago, Ill., 545,736. Filed Apl. 26, 1894.
Relates to a double lamp of the type in which the carbons are normally kept apart until the current is turned on.

Carbon Holder for Electric Arc Lamps, T. E. Adams, Cleveland, O., 545,755. Filed Feb. 15, 1895.

Adjustable Support for Electric or Other Lamps, L. Goddu, Winchester, Mass., 545,485. Filed Mch. 30, 1894.

Miscellaneous:—

Electric Igniting Apparatus for Gas Engines, H. Thau, New York, 545,553. Filed Oct. 20, 1894.

Electric Time Check Receiver, C. K. Jardine, Georgetown, British Guiana, 545,696. Filed March 26, 1895.

Electrical Annunciating-Target, O. Kauffmann, Sacramento, Cal., 545,699, Filed Nov. 15, 1894.

Railways and Appliances:

Support for Overhead Electric Conductors, M. Hanford, Malden, Mass. 545,495. Filed April 25, 1894.
A trolley wire connector.

Trolley Guard, J. T. Moody, W. Shawd and A. J. Baker, Springfield, Ohio, 545,520. Filed Feb. 23, 1895.

Trolley Arrester, H. F. Hildebrandt, Rochester, N. Y., 545,649. Filed May, 6, 1895.
Automatically arrests and controls the trolley arm when it becomes disengaged from the line-wire and brings it into a position where it can do no harm.

Trolley, Z. T. Furbish, Augusta, Me., 545,686. Filed July 12, 1895.
Details of construction.

Trolley-Wire Support, J. W. Meaker, Evanston, Ill., 545,806. Filed Nov. 17, 1894.
Consists of a clip of thin sheet metal held in position by a wedge.

Bond for Electric Railways, E. S. Wheeler, Saugatuck, Conn., 545,833. Filed Jan. 14, 1895.
A chair with a flange and a draw bar engaging with the opposite faces of the webs of the rails.

Electric Brake, W. L. Hedenberg, New York, 545,496. Filed May 7, 1894.
A controller is arranged to throw one or more coils into circuit at a time, whereby the shoes will advance towards the wheels to apply the brake with more or less force.

Switches, Cut Outs, etc.:—

Safety Appliance for Electric Conductors, A. E. Hutchins, Detroit, Mich., 545,629. Filed May 5, 1893.
An automatic cut-out put in operation by the sagging or the breaking of a wire.

Telegraphs:—

Telegraph Key, G. F. Philbrook, Lisbon Falls, Me., 545,532. Filed Jan. 19, 1895.
A weighted and pivoted button arranged to fall when the operator's finger leaves it, and provided with a contact-piece which closes the circuit.

Teletyper, C. Spiro, New York, 545,637. Filed Dec. 18, 1894.
An arrangement by which a typewriter can be used for transmission or for regular office work.

LEGAL NOTES.

SOME LIGHT ON THE OLD WESTERN UNION-AMERICAN BELL ROYALTY LITIGATION—A FAVORABLE BELL DECISION.

In the United States court of appeals, at Boston, last week, a decision was rendered in the case of the American Bell Telephone Company, appellant, vs. the Western Union Telegraph Company, et al., complainants, appellees, in favor of the appellant.

This suit, which was originally brought in the circuit court by the Western Union Telegraph Company, the Gold & Stock Telegraph Company and the American Speaking Telephone Company, and continued by the Western Union Company, was for an accounting from the Bell Company alleged to have been the right of the plaintiffs under certain contracts made by them with the Bell. (See the contract in THE ELECTRICAL ENGINEER, Aug. 28.)

The contracts gave the Bell Company the right to use certain inventions for the transmission of messages that were owned by those companies, the Bell Company agreeing to pay certain royalties. The plaintiffs claimed there was a large sum due them for royalties, and this the Bell Company denied. After the case was begun in court, hbot sides made a stipulation referring the case to Hon. John Lowell as master, "to hear the parties, report the facts and his rulings on any question of law arising in the case" to be taken.

The master heard the parties, and decided what his decision upon the facts and law would be, and communicated them to the counsel. Afterward he filed his report in the clerk's office, whereupon the Western Union Company, et al., the decision of the master being against them, moved the circuit court to allow them to dismiss their bill without prejudice to the bringing of another action for the same cause.

That court did allow them to have their bill dismissed without prejudice, whereupon the Bell Company took this appeal, claiming that at that stage of the case the lower court had not the right to dismiss the bill.

The court of appeals holds that the contention is right. W. G. Russell and J. J. Storrow for appellant; J. H. Benton, Jr., for appellees.

SIEMENS-HALSKE RAILWAY LITIGATION.

THE Siemens-Halske Electric Co. has sued the Metropolitan Elevated Railroad Co. of Chicago, for infringement of its third rail system put in by the General Electric Co., and has asked for an injunction.

THE TESLA PATENTS.

THE Westinghouse Electric and Manufacturing Co. has issued a circular directing attention to its Tesla patents, under which it is suing the General Electric and Stanley Cos., and asserting that these patents control all the developments of polyphase and multiphase working, both for lighting and for power.

"RELATIVE to the Data Sheets which you are publishing, I take great pleasure in adding my statement to that, doubtless, of all who have the privilege of receiving them, that they are of great value both as to the matter and as to its method of presentation."

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE QUAKER CITY DYNAMO AND MOTOR.

THE accompanying engraving illustrates the new dynamo and motor just brought out by the Quaker City Electric Co., of Philadelphia. This machine has been designed to meet the demand for a high grade machine for isolated lighting plants at a low cost. The frame is made of cast steel, the commutator of tempered copper, and the insulation and other materials used

QUAKER CITY DYNAMO AND MOTOR.

throughout in the construction of the machine are of the best quality suited to the purpose. The improved self-feeding brush holder permits the machine to be reversed, a most desirable feature for elevator motors. These machines, at present built in sizes ranging up to 25 H. P., are provided with self oiling bearings and regulate automatically between full load and light load.

PACKARD TRANSFORMERS.

The Electric Appliance Company are showing a good unsolicited testimonial letter on the Packard transformer from a customer who states that he has a large assortment of transformers on his lines, scattered among which are quite a large number of Packard transformers. During a recent severe storm of lightning eight transformers of almost as many different makes were completely burned out, while the Packard transformers were not injured in any way. The manufacturers claim that the way they are building the Packard transformer now, it is practically impossible to burn it out.

CROCKER-WHEELER ELECTRIC CO.

AFTER a continuous run of one thousand hours—Sundays excluded—the Crocker-Wheeler Electric Co. have caught up with their orders, which since their fire in the spring have been doubled. They have nearly replaced, also, their stock of parts and are therefore in position now to serve their numerous customers with greater promptitude than has recently been possible. When the magnitude of the disaster that fell suddenly upon this company is remembered, the feeling of pleasure and satisfaction will be general, at the rapid and gallant rally made by this standard concern which has done so much to foster and promote the electric power industry.

THE INTERNATIONAL ELECTRIC CO. OF ST. LOUIS

There comes to hand an announcement of the location in St. Louis of another factory for the manufacture of incandescent lamps. The style of the new company as incorporated under the laws of the State of Missouri, is the International Electric Company. The location of their factory is 19th and Olive streets, St. Louis, being within three blocks of that city's new Union Station. Their factory building is modern in every respect, being five stories high and especially adapted to the work for which it is to be used. The manufacture of the incandescent lamps is in the hands of Mr. J. M. Davey, who, for some ten years has been identified with the incandescent lamp business. The new lamp now being put upon the market about September 1st will be known as the "Davey High Grade." The object of the new company is to furnish a strictly high grade lamp that will appeal for approval alike to the central station, isolated plant and trade in general. The business management is in the hands of H. G. Ferguson, who has been actively identified with several large central stations in the West and who is familiar with electrical matters both theoretically and practically.

WESTERN TELEPHONE CONSTRUCTION CO.

The Effingham, Ill., Telephone Co. have awarded to the Western Telephone Construction Co. of Chicago the contract for 100 telephones and switchboard complete. The Western Co. have also furnished the Columbus Memorial Building in Chicago with a private telephone exchange which, it is asserted, surpasses for elegance and efficiency, anything else in this country. The switchboard is mounted on an oak table with nickel plated portable telephones. Among the recent shipments have been orders for Mexico and Yokohama, Japan.

NEW YORK NOTES.

MR. J. W. GODFREY, sales manager for the India Rubber & Gutta Percha Insulating Co., returned from Europe last week on the "New York," accompanied by his family and his nephew, Mr. R. J. Simes. What Mr. Godfrey has not seen is not worth the attention of the natives.

ROCHESTER, N. Y. has had another high voltage sensation, when H. W. Sherman received 2,000 Brush volts, but, like Frank Grover, was saved by his shopmates in the station, and was restored to consciousness under the rules of immortality enforced by Supt. G. A. Redman. It is far harder to kill a man by electricity at Rochester than at Sing Sing.

THE GOULDS MANUFACTURING COMPANY, Seneca Falls, N. Y., report the following sales of their triplex power pumps: Plattsburgh Light, Heat & Power Co., Plattsburgh, N. Y., one 1¾" x 2½" triplex power pump to be operated by electric motor. Mineral Farm Consolidated Mining Co., Aspen, Col., one 6½" x 8" triplex power pump and 5 H. P. motor for operating it. Bagnall & Hilles, Yokohama, Japan, one 5" x 8" triplex power pump to be driven by electric motor.

MR. EDGAR NEWMAN, of the firm of Schminke & Newman, 321 Magazine street, New Orleans, was in New York last week, incidental to a trip through the East. This concern represent the Nuttall, Beacon lamp, Baltimore car truck, Packard converter, Backus motor, Helios lamp, Safety wire and other specialties and have built up a large and growing trade in their Louisiana territory. Mr. Newman speaks most hopefully of the outlook.

WESTERN NOTES.

MR. W. H. MCKINLOCK, president of the Metropolitan Electric Co. of Chicago, has been through the East on business.

GRIER BROS., the Western Managers of the Bryant Electric Co., of Bridgeport, Conn., have removed from 1532, the Monadnock, Chicago, to 1436 in the same building.

THE BRYANT ELECTRIC CO. are getting out a new catalogue of their well known specialties, which they expect to have ready for distribution early in September.

THE PARTRIDGE CARBON CO. of Sandusky, O., write us that their carbon brushes are coming more and more into favor every day. The sales have more than doubled during the past year.

THE STANDARD ELECTRIC CO. find it necessary on account of the large number of orders on hand and the prospects for new business, to increase their facilities. Negotiations are now under way to secure new quarters.

MR. WILLIAM S. LOVE, who is well known in electrical and engineering circles in the West, has been appointed western agent for the Abendroth & Root Mfg. Co., of New York, and will have his headquarters at their office in the Monadnock Block, Chicago.

S. F. B. MORSE, of Chicago, who, as every one knows, is the popular representative of Kerite specialties in the West, has decided hereafter to drop the "& Co." from the name of his firm, and will henceforth "go it alone." We wish him every success.

THE ELECTRIC APPLIANCE COMPANY are making a special effort on telephone line materal, and are prepared to make exceptionally low prices on copper and iron line wire, pony glass insulators, pins, brackets and cross arms; making shipment in all cases promptly from Chicago stock.

PHILADELPHIA NOTES.

THE ELECTRICAL MAINTENANCE CO. of 50 Broadway, W. J. MacConnell, general manager, has opened a branch office at 1111 Betz Building, Philadelphia, and has placed Mr. J. W. Cregar in charge.

☞ ***Departmental items of Electric Light, Electric Railways, Electric Power, Telegraph, Telephone, New Hotels, New Buildings, Apparatus Wanted, Financial, Miscellaneous, etc., will be found in the advertising pages.***

THE
Electrical Engineer.

Vol. XX. SEPTEMBER 18, 1895. No. 385.

THE NEW STORAGE BATTERY PLANT OF THE BOSTON EDISON COMPANY.

BY

HISTORICAL.

ABOUT three years ago Mr. C. L. Edgar, general manager of the Edison Electric Illuminating Co., of Boston, made an extended tour through Europe, during which he made a careful examination of the workings of all the chief central lighting stations where storage batteries were being used as auxiliaries. He found many such stations in successful operation, and was most favorably impressed with the advantages offered by such installations.

Appreciating that in the most completely equipped and most carefully managed plants and systems there were times and conditions ever and anon arising and to be met when an efficient and reliable auxiliary would be most valuable, as in the case of an accident to engines or dynamos, an unusual demand for current at some unexpected moment, or the necessity for securing an even balancing of an extensive lighting and power system, Mr. Edgar became strongly impressed with the value of a good storage battery plant for the purpose, and so reported to his directors on his return home.

The result was, that after completing what is known as the Third Station, situated on Liverpool Wharf, Atlantic Avenue, Boston, with a very extensive steam and generator plant, it was determined to install a battery plant as an auxiliary. They accordingly contracted with the Accumulatoren-Fabrik Aktien-Gesellschaft, of Berlin, Germany, for a battery plant of the now well known and efficient Tudor type, which for about eighteen months has been in very successful operation.

The company's business continuing to grow so rapidly, and the demands made upon the resources of what is called their Head Place Station increasing month by month, they were compelled to add to its capacity. This they did by erecting a five-story building adjoining the station and equipping it as a storage battery plant. The work now being completed and the battery in regular use, some account and description of it cannot fail to be of interest.

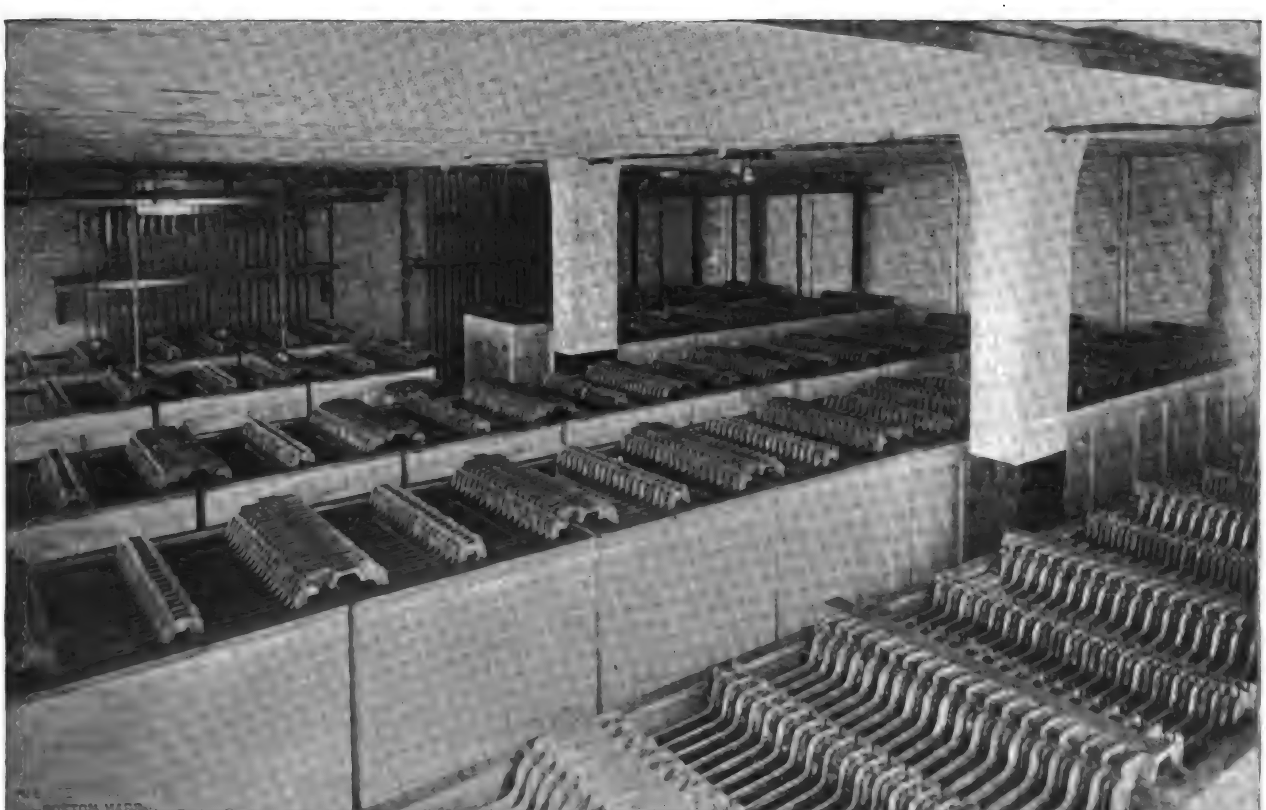

FIG. 1.—STORAGE BATTERY ROOM, HEAD PLACE STATION, EDISON ELECTRIC ILLUMINATING CO., BOSTON, MASS.

THE BATTERY.

The entire third, fourth and fifth floors of the new building are occupied with the battery which is composed

of 144 cells of the well known Tudor type, arranged in rows, as shown in the accompanying engraving, Fig. 1, and suitably connected with the rest of the lighting system as will be described later. Each cell is composed of a stout wooden box, lead lined, 3 ft. 10 in. long, 3 ft. 4 in. wide and 3 ft. deep. In this box are suspended the plates, each cell having 18 positive and 19 negative frames standing on edge. Each positive frame is composed of 16 plates 7 inches square; while each negative frame has four plates 14 inches square. These plates are all secured in their respective frames by lead strips soldered.

The floor space of the battery rooms is about 40 ft. by 36 ft., the cells being arranged in six rows as shown. The connections between the cells and switchboard are flat copper bars ½ inch thick and from 3 to 6 inches broad, according to requirements. Noting particularly one side of the entire system, all the 42 cells can be connected in series, while in addition a certain number have direct connection with the switchboard, so that by the automatic regulation, any number of cells, from 42 to 72, can be used in series for discharging. There are thus, 30 copper bars in each side of the system, 60 in all, and two neutral bars, which lead from the battery room to the switchboard. These bars are all supported overhead by iron hangers with fibre insulators.

In erecting this building for such a purpose, particular care was taken to secure good insulation. To this end the floor is made throughout of slate. On the floor are placed slabs of slate; on these are placed round porcelain insulators, and on these the cells stand. The voltage of each cell on discharge is 1.75 at the lowest, but averages about 1.85. On charge the voltage varies from 2.1 to 2.5.

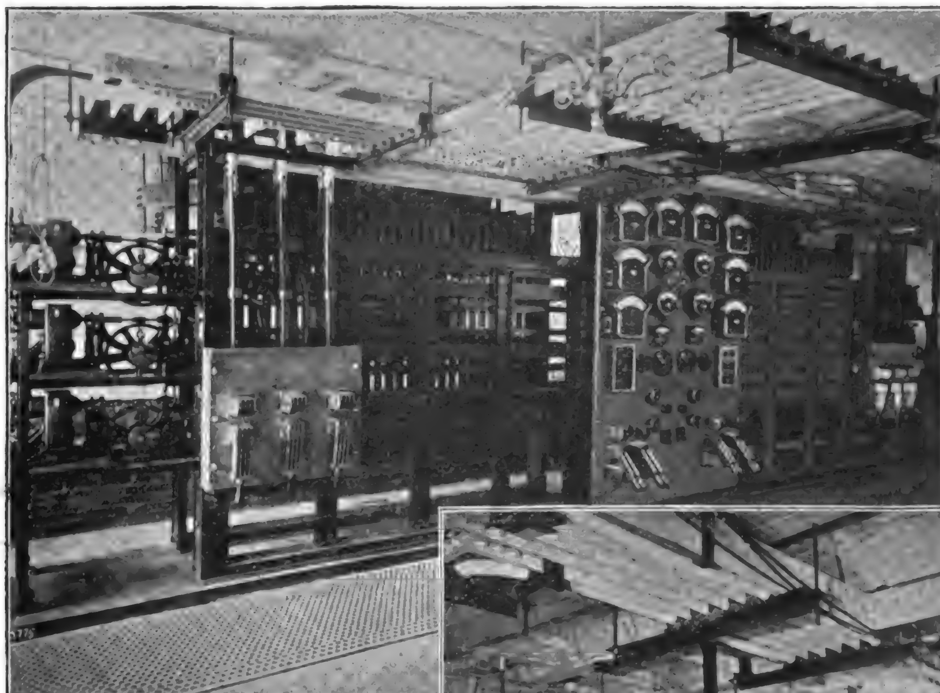

Fig. 2.—The Storage Battery Switchboard.
